The prognosis in either disease is sufficiently grave. A diabetic, however, after the age of fifty, with careful dietetic management, may prolong his life for many years and maintain a fair condition of health. Tuberculosis also, developing after middle age, often assumes a relatively benign and nonprogressive character. The lesions in the lungs are frequently of a fibroid type, tending to spontaneous arrest. Such a consumptive with suitable hygiene, diet, and careful regulation of his life may live out all his days and die of some unrelated disease. But usually when diabetes and tuberculosis are associated in the same individual, the mortality is so high as to make treatment of little avail. Naumyn, however, has reported the case of a diabetic, aged fifty-three, who was attacked with tuberculosis in both lungs and a tuberculous ulceration of the larynx, in whom the pulmonary process was arrested, the ulcer of the vocal cord healed, and the patient was in good health sixteen years later. Fraenkel has reported a case of apparent cure in a diabetic physician with well marked tuberculosis of the lungs. Such cases, unfortunately, must be regarded as extremely rare. A practical conclusion which cannot be too strongly urged is the importance of safeguarding the diabetic from tuberculous infection. Diabetics should be rigorously isolated from members of their family who are tuberculous. A recent case at the tuberculosis clinic of the Presbyterian Hospital well illustrates the danger of household infection. A young Irishman, who has been a diabetic for a year and a half, has lived in a tenement with his married sister, who has for three years been a consumptive of rather careless habits. Five months ago he began to cough and has now a well marked lesion of the right upper lobe. A similar case is related by Rénon. A man of sixty, who had been a diabetic for many years, but whose general condition was excellent, had a daughter aged twenty-one who became tuberculous. The father was intimately associated with her while she was taking climatic treatment in the south of France. The daughter died in a few months of acute phthisis. The father also was attacked with tuberculosis of the lungs of a rapidly progressive type, and died several months after the death of his daughter. Obviously, diabetics should not be received in hospital wards which harbor consumptives, nor should they frequent health resorts which are visited by large numbers of tuberculous patients.

Of six cases of associated diabetes and tuberculosis, recently under observation at the tuberculosis clinic of the Presbyterian Hospital, in all but one the diabetes preceded the development of the pulmonary disease. In this case the patient was undoubtedly tuberculous at least a year and a half before the appearance of any diabetic symptoms. Her

diabetes developed during pregnancy and she was delivered of a seven months' child which lived eight weeks. In four cases the tuberculosis developed eighteen months, twelve months, seven months, and two months, respectively, after the patients were known to be diabetic; in the remaining case the time could not be ascertained. This patient, a Hungarian Jewess, died seven months after the development of her tuberculosis. Three of the six patients were Hebrews. In four of the patients the family history was negative, both as to diabetes and tuberculosis, in one case a maternal aunt had diabetes, and in one, as already noted, the patient was probably infected with tuberculosis by a consumptive sister. Four of the cases were afebrile, and in the other two the temperature at no time has been above 100° F. The cases were equally divided as to sex. In the three women pruritus vulvæ was a marked symptom. In four out of the six frequent and considerable hæmoptyses were present. Tubercle bacilli were found in the sputum of three and were absent in three patients. In one patient it was possible to demonstrate the presence of glucose in the sputum with the phenylhydrazin test. The urine showed a strong reaction for acetone in all patients, and in one diacetic acid was also present. A trace of albumin was found in four of the six urines examined. The largest total quantity passed in twenty-four hours was seven and a half quarts, the highest specific gravity was 1.047, the greatest percentage of glucose noted was 7.2, estimated by the polariscope. In one case glucose was present in a urine of very low specific gravity, 1.009. The appetite was excessive in one patient, good in two, variable in two, and poor in one. Of five patients in whom the patellar reflexes were tested, they were abolished in but one. Bouchardat first directed attention to the fact that in diabetes the knee jerk is frequently absent. In one case a complicating laryngeal tuberculosis was present. In the case showing the highest specific gravity and greatest sugar content of the urine the patient several times appeared to be threatened with coma, as evidenced by great muscular prostration, irritability, sighing dyspnoea, drowsiness, and syncopal attacks. The husband of this patient has recently been attacked with tuberculosis of the lungs—apparently a clear case of conjugal infection. In a case of combined tuberculosis of the lungs and diabetes in a Cuban at St. Joseph's Hospital there was an extreme degree of ichthyosis of the skin of the entire trunk and limbs. In this case, as in a similar one reported by Lebert, the ichthyosis had existed for many years prior to the diabetes and tuberculosis.

The majority of the cases of this association of tuberculosis of the lungs with diabetes which I have seen have been in dispensary practice, and it is felt that as a rule in such practice insufficient care is taken in supervising the details of treatment of the diabetic element. In recent years, through the installation of nurses and better equipment of the outdoor departments of hospitals, there has been great improvement in the dispensary care of tuberculous patients, but the diabetic is still comparatively neglected. His diet should be at least as carefully prescribed as his medicines, and the ready made printed diet sheet does not meet this indication. A valu-

able and seemingly practicable extension of the work of district nurses and the diet kitchen, which has been so helpful in the tuberculosis clinic, would be instruction in the preparation and supervision of food for the diabetic, which is now very imperfectly attended to in the tenement home. This comparative neglect of diet is a difficulty which is also experienced in the care of the well to do diabetic. It is not possible in this country to send diabetics to well managed institutions where there are the modern facilities for dietetic treatment under expert supervision which exist abroad. It is probable that the patient who does well at Neuenahr, Carlsbad, or Vichy is as much indebted for his improvement to the painstaking attention to dietetic detail of the local physicians, and to the intelligent co-operation of the hotels and pensions in providing an attractive, ample, and varied menu which makes the dietetic cure a pleasure, as to the alkaline mineral waters which are drunk so seriously in these places. To Külz is due the credit for having first emphasized the importance of institutional treatment for the diabetic. In both tuberculosis and diabetes the careful regulation of the patient's daily life is the important factor, and this can, in most cases, probably be most easily and most efficiently carried out in a well conducted sanatorium. When the two diseases coexist the care of such a case is a dispiriting and usually fruitless task for the physician, but the unfortunate patient's condition may, at least, be made more tolerable, his life may be prolonged, and in rare cases he may, perhaps, recover through wisely directed and faithfully continued adherence to the necessary hygienic and dietetic requirements.

## THE ASSOCIATION OF TUBERCULOSIS CLINICS OF THE CITY OF NEW YORK.

BY JAMES ALEXANDER MILLER, M. D.,

New York,

President of the Association.

The tuberculosis clinic has taken its place as a permanent institution in our community. This fact is not as yet universally recognized, but I take it that in a few more years every dispensary will have discarded the old haphazard methods, and tuberculosis patients will everywhere receive treatment based as much upon the social environment as upon the physical condition of each case.

The study of these two factors in their relation to each other is the distinguishing feature of special tuberculosis clinics which mark the beginning of organized social service in the practice of medicine.

*Main Features of a Tuberculosis Clinic.*—The more evident advantages of the special tuberculosis clinics may be summarized somewhat as follows:

First. Greater individual attention and study are given to each patient by physicians who are more interested and more skilled in their treatment.

Second. The control of the patients both in the waiting and consultation rooms is more complete, so that any danger of infection to other patients is minimized.

Third. By means of visiting nurses, the social conditions and home surroundings of each case are studied and supervised in conjunction with the advice and treatment given at the clinic. A widespread campaign of education is thus carried on in the tenements.

Fourth. Extra diet in the form of milk and eggs is given to such patients as are unable to supply themselves. Such diet is dispensed upon the physician's prescription as a part of the treatment, and not as charitable relief.

Fifth. Close association with charitable societies, sanatoria, hospitals, and other institutions enables the clinic physicians to know which of such facilities are available for any patient, and to place any such care or assistance at his disposal as may be necessary.

Sixth. Patients who are discharged from hospitals and sanatoria, upon returning to the city, are supervised both at home and at the clinic, and the danger of a relapse is consequently much diminished.

Seventh. An excellent opportunity is offered to younger physicians to become skilled in the management of pulmonary tuberculosis. The training in early diagnosis is especially valuable and much needed by many general practitioners.

It is thus evident that the tuberculosis clinic constitutes a centre for accurate and reliable advice upon all of the varied problems which this disease presents, and should therefore become more and more valuable as its advantages are more widely known and more universally utilized.

*The Development of the Special Clinic Idea in New York.*—The first of these clinics was organized in 1903, and during each succeeding year one or more new clinics have been established, until there are now ten special tuberculosis clinics in the borough of Manhattan. They were each organized independently, and have endeavored to work out the

were truly reception days in the tenements! It is small wonder that patients sometimes moved away to escape our multiplied ministrations. This picture is not overdrawn, but represents fairly accurately the conditions as they existed eighteen months ago.

*Improvements in Methods.*—The first step toward improvement was the requirement of an accurate medical report in each case as a basis of its consideration for relief. To accomplish this the physicians had to remodel their ideas to a more or less uniform standard.

A card for such reports was carefully prepared, based upon the classification of the National Association for the Study and Prevention of Tuberculosis, and for reference this classification was printed in full upon the reverse of the card. This in itself proved a fruitful source of elementary education.

The reports upon the social conditions were furnished by the Charity Organization Society investigators, and, as might be expected, were excellent. They often opened the physician's eyes, and led to many a change in the plan of management. The Charity Organization Society agents on their side learned the importance of relying on medical opinion for diagnosis, and to modify the tendency to which they were inclined, of keeping the families of tuberculosis patients too near the border line of need.

As the physicians began to see the necessity for considering other factors in the treatment of the family than the mere prescription for the sick person, so the charity workers, on the other hand, came to realize the necessity of finding some way for supplying food, rest, air, and sunshine in plenty to the tuberculosis patient, without disastrous moral effects; for if it were not possible to supply these essentials in abundance, it were far better to abandon home relief and bend all energies to getting the patient into a suitable hospital.

In the proper disposition of cases, whether suitable for sanatoria, hospitals, country care, day camp, or home treatment, we all—doctors and nurses and charity workers—gradually came to something approaching a uniform notion.

In the delicate question of milk and eggs distribution from the clinics, that disputed territory of charity and therapeutics, our ideas became clearer, with the result of much more careful supervision, and I may add considerable curtailment of its use.

*Cooperation with the Health Department.*—But we were still laboring with the problem of unnecessary duplication of work. The first move towards its solution was to obtain the consent of the Health Department to consider the visits and reports of the clinic nurses satisfactory substitutes for those of its inspectors and nurses. The next was the closer cooperation between clinic nurses and charity agents, so that their visits supplemented rather than paralleled each other. These changes resulted in considerable relief to the patients by eliminating many unnecessary visits in their homes and also in a great saving of unproductive and conflicting effort.

*The City Is Apportioned to the Clinics by Districts.*—The next step was a long one. It was undertaken with trepidation, but the result has been a great success.

The various clinics adopted the district system. The advantages to be derived from such a system are obvious and they have all been realized. The patient no longer takes a long fatiguing journey to the clinic, and he makes the shorter trip oftener; the nurses can visit more patients and each one more frequently; the physician can exercise better supervision of each case, and require more careful attention to details from both patient and nurse. The saving of time and labor is enormous.

Our method consists simply in referring each applicant at a clinic who does not live in the district to the proper clinic, a reference card being used, one half of which is given to the patient, and the other mailed to the clinic. Should a patient so referred not appear within a week, he is looked up at his home by the nurse from the clinic which has received the notification of his transfer.

#### Explanation of map:

##### MANHATTAN.

NOTE.—Manhattan applicants for examination or treatment should apply at the dispensary in the district in which they live. The dispensary districts are shown on the map.

##### DISPENSARIES.

Department of Health, 55th St. and 6th Ave., weekdays, 9 a. m. to 4 p. m. Mon., Wed., Fri., 8 to 9 p. m.

Bellevue Hospital Dispensary, Foot of East 26th St., weekdays 1 to 3 p. m.

Gouverneur Hospital Dispensary, Gouverneur Ship, Mon., Wed., Fri., 2 to 4 p. m.

Presbyterian Hospital Dispensary, 70th St. and Madison Ave., Mon., Wed., Fri., 1:30 to 3:30 p. m.

Harlem Hospital Dispensary, 136th St. and Lenox Ave., weekdays 9 to 4 p. m.

Vanderbilt Clinic, 60th St. and Amsterdam Ave., weekdays 2 to 3 p. m. Mon., Wed., Fri., 9 to 10:30 a. m.

New York Dispensary, 137 Centre St., weekdays 11 a. m. to 12:30 p. m.

New York Hospital Dispensary, 8 West 10th St., weekdays 2 to 4 p. m.

Mt. Sinai Hospital Dispensary, Madison Ave. and 100th St., weekdays 10 to 11 a. m.

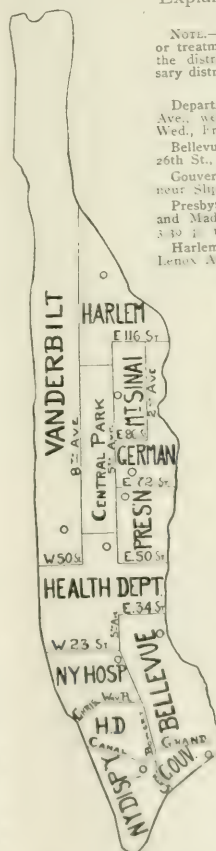

German Hospital Dispensary, 76th St. and Park Ave., weekdays 2 to 4 p. m.

Health Department, Bronx, 31 Ave. and St. Paul's Place, weekdays 2 to 4 p. m.

*Theoretical Objections to the District Plan.*—The chief objections that have been raised to such a system are: 1. The reluctance of the patients to give up their free choice of physicians or institutions; 2, the unequal distribution of numbers among the clinics, and 3, the hesitation on the part of teaching institutions to part with their interesting clinical material.

*The District Plan a Complete Success.*—In experience, none of these anticipated objections has

materialized. There have been practically no complaints on the part of the patient; the numbers at all of the clinics have increased because of more efficient visiting and the better care given to the patients; and a little adjustment of district boundaries easily corrected the slightly unequal distribution that

<sup>1</sup>See map and directory.

resulted at first; and as for teaching, all clinics have had more material than ever before.

It would seem that this classification by districts is much more satisfactory than one upon any such proposed basis as race, creed, or color. The individual clinic can quickly adjust itself to the characteristics of its own districts, and certainly, for purposes of dispensary cooperation and consistent social service this system is admirable. It also checks the abuse of dispensaries by patients who are able to pay.

Eventually we hope to have each district so compact that every house in it will be familiar to the clinic nurse. This will require the cooperation of a much larger number of the dispensaries in the city, but this does not appear impossible, and I know of no other way to effectively control the spread of tuberculosis in the tenements.

*Clinics for Children Are Established.*—A few months ago the majority of the clinics established a separate class for children. The main object was to institute as a routine procedure the thorough examination of all children in the families of our patients and thus discover, if possible, latent and unsuspected cases.

This has proved a most interesting and valuable experiment. In a collective investigation we have examined 431 such children, and found that sixty-two of them, or somewhat over fourteen per cent., either had or were strongly suspected of having pulmonary tuberculosis. The diagnosis in these cases is more difficult even than in the adult, and the various tuberculin tests have been of great value in many doubtful cases.

It seems evident that, contrary to the usually accepted ideas, pulmonary tuberculosis is very frequent in children, that they are infected in a large proportion of cases from close association with advanced cases in their own families or homes, and that the signs and symptoms of the disease remain for a long time so obscure that they would escape detection except for a most rigid examination by a trained observer.

If this is so, it opens up a tremendous field for productive prophylactic work in ferreting out these children, and providing for their care, both before and after they may have become infected.

*The Formation of the Association of Tuberculosis Clinics.*—All of this work that I have endeavored to describe was, as we have seen, developed largely through the membership of the representatives of the various clinics in the relief committee of the Charity Organization Society.

When this fund was exhausted and our committee disbanded a few months ago, it was our firm conviction that it would be most unfortunate to lose the benefits that we had gained by cooperation, and that, on the contrary, we should, if possible, form a closer union between the various clinics to continue and enlarge the work already begun.

Such a union was consequently established by the formation of the Association of Tuberculosis Clinics of New York City.<sup>2</sup> This association is composed

ORGANIZATION OF THE ASSOCIATION.

Officers.—James Alexander Miller, M. D., president; John H. [illegible], [illegible]; Frank H. [illegible], secretary. No. 105 East Twenty-second street.

of active members, who are the representatives of the various clinics, and of associate members, who are selected as representing the different charitable, religious, and social societies and institutions in the city which are coming in contact with tuberculosis as a constant social problem.

It is our aim to enlist the active cooperation of all these agencies in such a way that in each district of the city the tuberculosis clinic may become the centre to which all workers among the poor will naturally turn for expert advice upon all questions and problems which may arise in regard to tuberculosis. To promote this end we are also planning the organization of a women's auxiliary to the association. This auxiliary would be composed of charitable women of standing and influence in the city, who would widen the interest in anti-tuberculosis work, and would take a personal interest in many individual cases, thus helping to carry out the physician's recommendations where otherwise it might be impossible. It is planned that each clinic should have its own separate auxiliary, the chairmen of which shall be associate members of the main association.<sup>3</sup>

*The Cooperation of All Physicians Necessary.*—It is now our foremost aim, however, to interest the physicians of the city in this movement. It should appeal to them especially, because the whole plan of organization is based upon the medical aspects of tuberculosis. We physicians have allowed the laity to run beyond us sometimes in the now widespread campaign against preventable disease.

In this organization, however, it is proposed that medical science shall lead the way, and in this we need the help of all physicians.

This means more than simply referring poor patients to the clinic in the proper district. It means especially a responsibility upon all physicians connected with any medical dispensary to influence their own institution to join in this work.

This may be done in one of two ways: First: By the organization of a special tuberculosis clinic with a visiting nurse, assuming the responsibility for the care of a district of the city, and joining our association; or, secondly: If such a separate clinic is not feasible, then the dispensary should refuse to treat pulmonary tuberculosis, and refer all such patients to the proper special clinic.

There are, at present, a total number of sixty-nine dispensaries in the borough of Manhattan. There is probably a need of twenty or twenty-five

John H. Huddleston, M. D., Abraham Jacoby, M. D., James C. Greenway, M. D., Alfred Meyer, M. D., James Alexander Miller, M. D., Henry S. Patterson, M. D., Henry L. Shively, M. D., Arthur M. Shady, M. D., Bertram H. Waters, M. D.  
Associate Members.—Robert W. Bruere, Association for Improving the Condition of the Poor; John J. Fitzgerald, the Society of St. Vincent de Paul; Miss Jane Elizabeth Hitchcock, Nurses' Settlement; Rev. Walter Laidlaw, the Federation of Churches; Miss Anna Maxwell, Visiting Nurses' Association of the Presbyterian Hospital and Vanderbilt Clinic; Dr. Walter Sands Mills, Department of Public Charities; J. K. Paulding, trustee of Bellevue and Allied Hospitals; Lawrence Veiller, Charity Organization Society; Gaylord S. White, Association of Settlement Workers; Dr. C. M. Cauldwell, St. Joseph's Hospital; Mrs. J. Borden Harriman, Civic Federation and chairman of Presbyterian Auxiliary; Mrs. Richard Irvin, Loomis Sanatorium; Mr. Henri Maillard, Société française de bienfaisance; Mr. Celestino Piva, Italian Benevolent Association; Miss Blanche Potter, Bellevue Clinic Auxiliary; Dr. Frederick L. Vuchenheim, United Hebrew Charities; Mrs. Henry Villard, Diet Kitchen Association.

<sup>2</sup>Since this article was written three clinics have organized auxiliaries with a membership aggregating nearly 200. The idea has met with unlooked for success, and been taken up with astonishing enthusiasm.

special tuberculosis clinics. A canvass is now being made of all these dispensaries to ascertain their attitude toward this district plan, and physicians can help very materially in determining what this attitude shall be.

*Complete Control of Tuberculosis a Possibility.*—For the first time in the history of this city, there seems to some of us a possibility of adequately supervising and subsequently controlling the spread of tuberculosis.

All students of this problem have come to agree that the breeding places of this plague are in the homes of the poor. It is in these homes that we plan to make our fight.

We ask the help and cooperation of all those whose work or interests bring them in touch with any of the varied aspects of tuberculosis.

18 WEST FIFTY-FIRST STREET.

#### TRANSFUSION: HISTORY, DEVELOPMENT, PRESENT STATUS, AND TECHNIQUE OF OPERATION.

BY GEORGE M. DORRANCE, M. D.,  
and

NATE GINSBURG, M. D.,  
Philadelphia.

There are few operations that deserve to be called life preserving to such an eminent degree as transfusion, and among these few there is hardly one that is technically so simple and so devoid of danger in its execution (Leisrink).

The possibility of saving life by the introduction of healthy blood into the circulation of one suffering from sudden loss or gradual depreciation of the vital fluid, naturally presented itself as a resource to the minds of the physicians of the earliest periods. Hebraic, Egyptian, and Syriac medical records all tell of the practice of this procedure in the various ages of which they speak; and steadily downward through the times of Greece and of Rome can traces, well marked and distinct, be discovered of its occasional adoption as a therapeutical resource. Nor was the operation lost sight of in the advance of modern times, for in 1492 we learn that one of the Roman pontiffs was submitted to it at the hands of a Jewish physician; that in 1615 an essay was written upon the subject by Libravius, of Halle; that in 1652 Polli, of Italy, contrived an apparatus for arteriovenous transfusion; and that in 1664 the process was fully described by Daniel, of Leipsic, as one to which he was in the habit of resorting (T. Gaillard Thomas). James R. Chadwick, of Boston, in an original communication in 1874 refers to the employment of transfusion on the person of "Naam," Prince of the Syrian army, who, when stricken with leprosy, to effect a cure, removed the blood from his veins and replaced it with other blood. Medea is represented by Ovid as offering to restore youth and strength to Pelias by replacing his aged blood with that of a young man.

Without discussing the credibility of these and similar statements, it was not until the year 1665 that Richard Lower, an Englishman, first published a complete description of the procedure to be followed in transfusion, and performed the operation upon animals. Denys, of Paris, in 1667, stimulated by accounts of Lower's success in England, experi-

mented on animals, and later in two instances successfully transfused a lamb's blood into the human circulation. The publication of Denys's results gave rise to the most violent excitement in Paris. One party laid claim to the discovery of a universal remedy which would restore health, youth, and vigor, quiet diseases of the mind, calm the most violent dispositions, and might even prolong life beyond its natural term.

The opponents of this operation contended that it was based on false premises, and sought to have its performance stopped. Laury, for instance, an eminent surgeon, maintained that certain particles of the blood were distributed to nourish certain parts of the body, and asked what would become of those ingredients of the blood, which Nature intended should produce the horns of a bull, if a bull's blood were introduced into the human circulation. He also thought that the stupidity and low instincts of the animal would thus be transmitted to the man. Through this writer's unfair efforts the operation was interdicted in France, unless done with the approval of a member of the faculty of Paris. Thus the operation of transfusion sank into oblivion not only in France, but also in other countries.

Blundell in 1818 revived the operation in England, and clearly demonstrated its beneficial effect on persons suffering from excessive hæmorrhage following childbirth. Following the three successful cases of Blundell of transfusion with human blood, Dumas and Prevost in France, and Dieffenbach and Panum in Germany, became very active in experimental work bearing on transfusion of blood from one individual into another. Panum showed scientifically that for transfusion on man, only human blood should be used. Kuhne gave a considerable extension to transfusion in his paper on carbonic oxide poisoning. Martin, in 1859, advocated transfusion in hæmorrhage of parturients. Neudorfer employed it in chronic anæmia, consequent upon purulent discharges; Nussbaum in chlorosis.

Of the most important are the labors of Hüter, who first introduced arterial transfusion. Esmarch, in a personal communication to Leisrink, stated that he performed transfusion on a person during the extirpation of a fibrocavernous tumor from the base of the skull, where much blood was lost, by pumping back new blood into the arm. Also in a case of exarticulation of the femur, Esmarch caught up the flowing blood, and drove it back directly into the femoral vein, following a procedure first recommended by Volkmann in 1808.

Dr. Walter Channing, of Boston, in a paper, published in the *Boston Medical and Surgical Journal*, at this time also strongly advocated the practice of transfusion in properly selected cases. Following these contributions the exponents of transfusion became numerous. Milne-Edward, Dieffenbach, Bischoff, Polli, and Nicholas all strove to elevate it to a legitimate position, but it has only been during the last twenty years that its claims have been admitted. Among later workers and writers on this subject, whose efforts have assisted the adoption of transfusion to save life, are: Oré, of France; Gesellius, of Russia; Hulse and von Bergmann, of Germany; Roussel, of Geneva; Avelling, McDowell, and Higginson, of England; and Crile, Murphy, and others of this country.

T. Lauder Brunton, in 1873, advocated transfusion as a means of preserving life in cases of coal gas poisoning. He states that in these cases the only hope lies in removing the poisoned blood and replacing it by healthy blood. This does not by any means always succeed; but occasionally the recovery from impending death is almost miraculous, as in a case where it was employed by Professor Hüter (*Berliner Klinische Wochenschrift*, 1870, p. 341). The patient, who was a strong, young man, was living in a hotel, and one night had a fire lighted in the stove of his room. Next morning he was found perfectly unconscious, his iris and cornea quite insensible, and his pulse small and rapid. His respiration was weak and intermitting. Just as everything was ready and transfusion of blood was begun, his respiration failed altogether. Notwithstanding this fresh blood was allowed to stream into the patient's radial artery; the poisoned blood was drawn from a vein, and respiration was kept up artificially. Gradually the pulse became stronger, spontaneous respiratory movements again began, and the cornea became sensitive. In about five hours consciousness returned, and in a few days health was completely restored. After recital of this remarkable case of recovery, Brunton was so profoundly impressed with the efficacy of transfusion as a means of preserving life that he also advocated its adoption in treating cases of strychnine poisoning, by blood letting in addition to transfusion. He also believed that the blood of lambs and calves could be transfused into the human being in the event of failure to secure fresh human blood, a procedure which has since been proved to be not only contraindicated, based on physiological grounds, but also fraught with great danger to the recipient. He believed the objection raised by Laury, two hundred years before his time, regarding the transmission of animal characteristics along with the blood of the donor, a theory untenable, and totally disproved by the experiments of Galton on rabbits.

Franz Gesellius, in a classical, historical, critical, and physiological study of the transfusion of blood, refers to the first case of recovery from carbon monoxide poisoning, in which pure blood was used in 1871. This distinguished scientist reviews the literature relating to this procedure, dwelling at length upon the practicability of employing defibrinated blood, the apparatus for transfusion, and a report of cases.

In reviewing the historical development of this procedure we are next attracted to the paper of the eminent physiologist, Bowditch, of Harvard University, published in 1876. Reference was made to the works of Gesellius and Hasse in transfusing blood of various species. In addition to these latter two experimenters, the work of Fiedler and Birch-Hirschfeld were mentioned, mainly along the same lines. The views held by Bowditch were mainly those advanced by earlier workers in this line of research, and are to be noted mainly for the indications offered for performance of transfusion. The notable monograph of T. Gaillard Thomas, published in New York in 1878, is a treatise on the intravenous injection of milk as a substitute for the transfusion of blood. While it is true that this in-

genious observer was inspired by the experiments of Hodder, of Toronto, Canada, in 1850 on cases of Asiatic cholera and also by the previous use of blood for transfusion and the failures that attended the operation, the record of his cases in which milk was employed as a substitute can hardly stand as a proof of the superiority of milk over blood. William Hunter, in 1880, based his opposition to transfusion of blood in the human being on the deleterious effects resulting from the blood, which was saturated with salt solution or a solution of sodium phosphate.

Coincident with the struggle for the survival of the operation of blood transfusion, the history of the development of the apparatus for carrying out the procedure offers an interesting tale. Contention over the advisability and practicability of employing defibrinated or undebrinated blood was waged along with the question of direct or indirect transfusion and the employment of blood from the same or varied species. Hunter, in spite of his pronounced views against the regular employment of transfusion as a routine procedure, admitted the most positive indication for the performance of transfusion, i. e., the sudden collapse from rapid and severe loss of blood. This single statement in a great measure offset his other arguments.

Blood of dissimilar species was proved to be impracticable and dangerous for purposes of introduction into the human circulation. Magendie, Panum, Ponfick, Landois, Hunter, Mittler, Wormmuller, Ploz, and Gyorgyai opposed the transfusion of blood of animals into the human circulation. They ascribed their reasons to dissimilarity in the properties of the different types of blood, and the resulting hæmoly-sis which took place. Experiments in the hands of a large number of workers in this field have proved conclusively the dangers attendant upon introducing blood of animals into the human circulation. Not only was no improvement noted in those cases in which it was done, but serious shock followed the operation, and in no few instances sudden termination of life. Hasse first employed arteriovenous transfusion in thirty-nine cases by introducing lambs' blood into the human circulation. Like those of others, his results were variable and in some instances fatal.

The question of the employment of defibrinated or of undebrinated blood is one which took many years to settle. Prevost, Bischoff, and Panum opposed the use of undebrinated blood on the grounds of the danger of thrombosis and embolism, which was the cause ascribed to the unsuccessful cases. Hunter believed that defibrinated blood was uncertain in action, sometimes quite harmless, and at other times highly dangerous, the result being entirely independent of the quantity injected or the care taken in injecting it. Until 1860 only thirteen cases had been recorded of the use of defibrinated blood (Magendie). In addition to Hunter, Ponfick, Landois, and Gesellius also experienced great difficulties in the employment of defibrinated blood.

The long unsettled question concerning the superiority of defibrinated or undebrinated blood was in a great measure dependent upon the type of instrument used to transfuse the blood. Those who performed direct transfusion naturally opposed de-

fibrination, while others who were compelled to employ a syringe or tube attached to a reservoir favored defibrinated blood, because only in this state could the blood be maintained in a fluid condition for reintroduction into the circulation.

Various instruments and tubes were employed for transfusion. Gesellius, Leisrink, and others employed a glass canula. Nicolas Duranty employed a cold syringe; McDonnell, a slight modification of Duranty's instrument; Higginson, a tube with a bulb attached, and later Aveling employed two canula attached with rubber tubing to a syringe, so that the blood could be sucked from the veins of the donor into the rubber bulb, and then by compression driven into the vessels of the recipient. It was also alleged that with this instrument the quantity of blood transfused could be accurately measured. Chadwick also employed Aveling's apparatus, first filling the bulb and tubes with water to avoid introducing air into the vessels.

It is obvious that with the development of direct transfusion by end to end anastomosis between the artery of the donor and the vein of the recipient (either by a mechanical method or by direct suture) that the questions of defibrination or undefibrination of blood and the employment of complicated, uncertain apparatus are swept aside. The procedure today is one of simplicity and of certain success in the presence of secure asepsis and good assistance. If any factor contributed to the severe symptoms in addition to the development of thrombosis and embolism in former days, tending to cause failure in its performance, the absence of sure asepsis was the principal cause.

#### *The Present Status of Transfusion.*

The indications for transfusion may be considered in two ways, from the physiological and clinical standpoint. It is indicated physiologically when the blood is greatly deficient in quantity or quality; clinically when the blood cannot perform its function of carrying materials from one point to another, or is not able to nourish the blood forming organs so that they can produce corpuscles. The clinical indications are divided into four classes. 1. Acute grave anemia due to hemorrhage; 2, chemical changes in the blood; 3, deficient coagulability of the blood; 4, in certain blood diseases.

1. For anemia due to acute grave hemorrhage, as from an accident, ruptured extrauterine gestation, or postpartum hemorrhage. In this variety the indication is clear and the results have been excellent.

2. Where chemical changes have occurred in the blood and the hemoglobin is not able to perform its interchange of carbon dioxide and oxygen, to its carbon monoxide poisoning and poisoning from its other aniline compounds. Here the transfusion is positive and the results good if the operation is performed early.

3. In hemorrhages where the coagulability of the blood is deficient, as in hemophilia, vitamin K, and in hemorrhage during typhoid fever. In hemophilia it will arrest coagulation and with the other methods of treatment stop the hemorrhage. In all cases will not cure the underlying cause. In all cases, however, transfusion will increase the blood count, all

the blood and make it possible to operate without excessive hemorrhage.

4. In certain blood diseases where the blood forming organs are not sufficiently nourished to produce corpuscles or where the blood corpuscles are deficient in numbers; as in extreme chlorosis, secondary anemias, unclassified anemias of childhood, and in pernicious anemia. In these diseases the transfusion should be repeated if marked improvement or permanent results are to be expected. In pernicious anemia, if this method of treatment is contrasted with the other methods in use, one should be perfectly satisfied with marked temporary benefit.

*Methods of Performing Transfusion.*—The operation of direct transfusion from an artery to a vein, which is the one that should be used, can be performed in several ways; but two factors must always be considered. First, the method must be one that will not cause the blood to coagulate while passing from the donor to the recipient. Second, the method must be simple and easy to perform if it is ever to come into general use.

Method No. 1. By means of the Crile tubes. The tubes were first employed by von Quirolo in 1895, and later modified by Payr, and still later by Crile. In this method the vein is passed through the tube of appropriate size and the free end turned back over the end of the tube, thus forming a cuff, which is tied in place with a fine linen ligature. The artery is then drawn over the venous cuff and tied in place. These tubes have the advantage of keeping the blood stream within the vessels and not permitting any foreign substance to come in contact with it. The disadvantages are that the tubes cannot be used by one not skilled in this work, and, secondly, it is very difficult and at times almost impossible to use them when the patients are very restless.

Method No. 2. By means of tubes of various substances. The tubes are easily applied, but within a very few minutes thrombosis occurs within them even under the most careful application.

Method No. 3. End to end anastomosis by direct suture. This method possesses no advantage over the other methods. Its disadvantages are: 1, That it is exceedingly difficult to perform; 2, the vessels contract; and, 3, thrombosis occurs at the line of suture after a few minutes.

*Technique of Operation.* The donor and the recipient are sterilized and then anesthetized by local infiltration. The arm of the recipient is constricted by an assistant to make the superficial veins prominent. Usually the superficial radial vein is the one selected, and if so should be exposed near the wrist for about one inch and two linen ligatures placed beneath it. The radial artery of the donor should be exposed at the wrist and two linen ligatures placed beneath it. Then the forearms are placed so that the point of the elbow is directed toward the elbow of the recipient. Then divide the radial artery and ligate the distal end with one of the ligatures, and divide the hemorrhage from the previous and following all constructed forearm ligatures, so by placing a small piece of gauze tape around the artery and connect it with the artery so as to compress the artery. Now divide the artery at the proximal end, and apply the ligatures to the distal end, thus dividing the artery from

the tube, ligate it in place, and remove the constriction of the artery, and allow the blood to flow. If the vessels are very small they may be dilated with forceps or small hæmostats. After the desired amount has been transfused the artery and vein are ligated, the tube removed, and the skin sutured. The amount to be transfused will vary with the disease, but it must always be remembered that too large an amount will raise the blood pressure. The operation may be repeated without any bad effects.

#### Report of Cases.

CASE I.—Pernicious anemia. Patient of Dr. D. Riesman, Polyclinic Hospital, Philadelphia. Transfusion by direct suture. Life extended six months. Full report later.

CASE II.—Pernicious anemia. Patient of Dr. D. Riesman. Unsuccessful. Report later.

CASE III.—Acute lymphatic leucæmia. Patient of Dr. Myers Solis-Cohen. Transfusion by suture method. Small amount transfused. The vessels contracted after a short time and very little flowed after that accident. No marked change in condition of patient.

CASE IV.—Shock and acute hæmorrhage. Patient of Dr. Levi J. Hammond, Methodist Hospital. Operation performed after a partial resection of the stomach. Recovery from shock and marked improvement in general condition. Patient died later from complication of gastric operation.

CASE V.—Extreme hæmorrhage from stomach. Patient of Dr. James Lloyd, Methodist Hospital, Philadelphia. On account of extremely restless condition of the patient the Crile tubes or suture method could not be used. The transfusion was tried with glass tubes lined with petrolatum. Operation was not a success. Patient died several hours after the second attempt. A very small amount of hæmoglobin was found in the urine after the transfusion, but I do not know if it was present before.

CASE VI.—Hæmorrhage during typhoid fever. Patient of Dr. Riesman, Jewish Hospital. Small amount transfused. No after hæmorrhage. Recovery. Full report to be published later.

All our patients were in moribund condition when we were given permission to operate.

1716 LOCUST STREET.

#### SOME INCONGRUITIES IN THE MEDICAL PROFESSION.\*

BY LY S. OPPENHEIMER, M. D.,  
Tampa, Fla.,

President of the Association of Seaboard Air-Line Railway Surgeons,  
Major-Surgeon, Second Regiment, F. S. T.

The title of this address may appear to some of you a pessimistic dissertation on the practice of medicine. No, it is merely an expression of a few striking matters that have appealed to me from time to time, in which I would enlist your interest.

No one denies our steady trend to betterment in all directions. Nevertheless, progress in ethics and our art is of course not in pace with the advancement in the sciences.

Some of my admonitions will, I trust, be salutary; all of them are sincere. I do not flatter myself that I have found solutions to these shortcomings; I hope to induce others better fitted to search for them. It is the privilege of truth to upset the traditional falsehoods that men cherish, but traditional contentment dies hard. We will probably always be creatures of custom and slaves of routine, for the laws of natural selection grind slowly.

#### Local Ethics.

Since the abrogation of the old code of ethics of the American Medical Association, State and county

medical societies have formed later ethical rules, often restricted by conditions of local import, sometimes, as I have personally observed, at variance with fundamental principles in ethics, of questionable utility, and ultimately working disaster to the body politic.

As an illustration: A county medical society adopted a law discountenancing all kinds of contract practice as being unethical, but exempted railway surgeons, military surgeons, and some others. Now, I am fortunately or unfortunately both the one and the other, but I cannot understand by what method of induction in ethics a principle is permitted to be violated arbitrarily. If the principle is correct the exception is immoral, and of course vitiates the spirit of the whole fabric. Contract practice *per se* is neither wrong nor undignified. The unethical feature in it is the same as in private practice, viz.: inadequate remuneration for the services, nothing more, nothing less; and a volume of hysterical pride or resolutions cannot alter this basic law of political economics.

#### Consultations.

Why does the consultant always get a larger fee than the attending physician? The latter has studied the case more closely before, is to have the care of it afterward; bears all the worry, anxiety, responsibility, criticism, does more thinking, more work, than the consultant.

Unless there are some special reasons for it, such as pertains to acknowledged experts, etc., the fees should be reversed, the responsible man getting the larger share, the consultant being really entitled to no more than a reasonable amount for actual services.

#### Fees.

Neither should we in every day practice be restricted to the conventional inflexible fee bill schedule. We should have a sliding scale according to the financial ability of the patient and character of services rendered: not fixed and absolute like that of the merchant. The opulent should pay according to his income, while the middle class pays the customary fee. Too many of these, like the indigent poor, get their services free.

What other calling or class daily gives to the public a considerable part of its time, skill, and means without remuneration, without ostentation, often enough without gratitude? Then why gauge our methods by the tape measure of commerce? I may be pardoned for perpetrating this apothegm, without fear of contradiction: The doctor's business is the only business whose business it is to destroy its business; or, if we must be commercial, and really we are by no means enough so for our own good, why not be consistent with our changed conditions?

Commodities rise, house rents go up, labor is better paid, riches become universal, yet the average doctor's fee is probably the same as when, in the embryonic period of our art, the priest, and later the barber, honored the leech with an occasional "case."

"Men may come and men may go," but the doctor's fossilized fees seem to go on forever, in more senses than one. The world acknowledges that our material emoluments are in no wise commensurate with the intelligence, knowledge, and responsibility required of every physician. Where is so much con-

\*Read before the Association of Seaboard Air-Line Surgeons, at a meeting held on February 10, 1910.

summate skill expected, yes, demanded, as that which deals with the first principles of existence itself, and the essentials which make that existence tolerable?

#### *In Court.*

When doctors are arrayed against each other in giving expert testimony in the courts, the doctor assumes, in spite of himself, a partisan attitude. He prompts his attorneys to confuse and belittle the testimony of his fellow physician on the witness stand. The expert's statements on the opposing side are discredited or made ridiculous, and the medical profession in general becomes the laughing stock of the jury, the press, and the public.

Now, these invidious situations should be obviated, and would be, if the physician would insist upon being true to himself first and last, and thus be true to the profession he is supposed to adorn. Honestly endeavor to meet and consult with the opponent's physician, and, so far as practicable, to harmonize conflicting views. Refuse to be forced by lawyers or employers into an unfair partisanship.

#### *Lack of Harmony.*

Through lack of harmony we have earned the contempt of corporate powers and politicians. Our weakness is as manifest as our boasts, and corporations are not slow to discover and take advantage of it. Where one of us will resent an unfair proposition, another will greedily accept. Where one set of medicos plead for the enactment of a just and righteous law, another set seditiously or surreptitiously opposes or tears it down. The pretense of harmony is as transparent as the selfish impulse which actuates it.

#### *Military.*

Speaking of military surgeons, I am reminded of the common routine of promotions in all branches of the service by reason of seniority. Thus, a surgeon with little or no special ability is promoted to a rank in which he is the acknowledged inferior to another whose commission dated one day or one year later. Is it for the best interests of the service to indefinitely continue this vicious precedent?

And here I shall call you to task for an apparent indifference that the medical profession in this country has evinced in the affairs of the army medical corps. For a number of years past, efforts have been made to increase the corps. Its insufficiency even on a peace footing is a conspicuous feature of our imperfect military organization. Twice has a bill passed the senate and been reported favorably to two congresses, still it has never become a law.

President Roosevelt in his annual message said, "The medical corps should be much larger than the needs of our regular army in war." Yet at present it is smaller than the needs of the service demands even in peace. The fault lies in our apathy, in our failure to demonstrate our patriotism in our own household. We praise the achievements of the Japanese military medical service, yet fail to lend our influence toward the advancement of our own. We surely have competent surgeons. We do not need to be "damned with faint praise." Give us enough trained men to do the work and we will agree to be second to none when the occasion demands. Urge your representatives to pass the law

promptly, and thus demonstrate at once your patriotism and your professional pride.

#### *Politics.*

The exigencies of an active physician's life usually preclude political aspirations. Besides, the successful physician is the one who is devoted soul and body to his art, hence, cares little for the bubble of political fame. But in this the physician does himself and the world a wrong. The public needs just such men in power.

Who is so well qualified to know the public needs as the ideal altruist, the ubiquitous friend, and confidential adviser, the doctor? He makes a model executive officer, and the public is not slow to recognize his virtues. Numerous examples of the successful doctor politician might easily be cited. Enter the arena if you feel convinced that you are needed there.

#### *Books.*

The fast increasing tendency of men who have some original ideas to become inspired thereby to write entire textbooks, is flooding our bookshelves, our brains, and our reading hours. "A few modest volumes would suffice to chronicle the real achievements of medicine; a library is necessary to tell the story of medical speculation and practice."

#### *Preventive Medicine.*

Our American lawmakers have at last passed essential health laws for the protection of the public which have for decades past been in active operation in Eastern "benighted" countries; but the rank and file of the medical army are still sadly derelict in the matter of public hygiene and preventive medicine.

We may appreciate our positions as guardians of the public health, but you will be told by health officers everywhere, that the average medical attendant is not as rigid or reliable in his supervision of infected houses or individuals as this responsibility demands. Earlier and persistent disinfection of infective excreta, and appreciation of the menace of typhoid and other stools for some time after convalescence and more rigorous protection against the milder tuberculous types are urgent needs.

To the failure of early diagnoses and consequent preventive discipline is ascribable the persistence of many preventable diseases.

#### *Isms.*

Many of us ridicule or attempt to obstruct or destroy *isms* or *pathies* with which we are not in accord, while at the same time our incredulity is vanquished without an effort by a new *ipse dixit* from our authority, or insufficient data.

We accept at once Brown-Séquard's orchitic elixir for perennial virility, or a new tuberculin cure for tuberculosis, or the dictum that the *Anopheles gambiae* is the sole carrier of the malarial parasite, or that the *Therbia bacillus* is only transmissible through the stools, or that every appendix and every diseased ovary should be removed or that opsonic indices or x ray radiographs are infallible, and a host of dogmatic doctrines that have not yet passed through the arctic. Says Dr. Max Nordau in his well known book *Entartung*: "Statements hitherto considered unimpeachable because

no one has ever questioned their validity must submit to the demand for proofs, and it then frequently appears that they have none."

Now as a matter of fact there must be a germ of truth in every *ism*. Those extraordinary or occult fads are based upon some sound physiological or pathological principle. We are not defeating them by derision, we will not destroy them by persecution. How few of us really know any more about them than do the most ignorant devotees that worship at their mystic shrines.

Would it not be more effective for our colleges to devote two or three hours each semester to an intelligent dispassionate study of each of them, free from ridicule or levity?

Indeed, our illiberalism in medicine smacks strongly of religious bigotry and intolerance.

### *Egoism.*

The standard of the medical profession is almost Utopian in its loftiness. We are the champions of humanity, charity, patience, self sacrifice, purity, knowledge, and wisdom. Hence, inconsistencies in our theories and practices are more glaring, and violations more flagrant than in any other sphere of life.

How incongruous that jealousy, envy, egoism, should enter such ennobling lives, whether actuated by mercenary greed or selfish ambitions, and beget social and professional demoralization.

Is it not a travesty upon that classical honor which is a vital element in our profession, for a physician who succeeds another in a case to inveigh against the ability of his absent predecessor? Is it not both undignified and cowardly?

Each one of us is the standard bearer and model of the entire body; and it is but a logical inference that the profession be held responsible for your shortcomings. We are in very truth our brother's keeper.

And so, when we chasten ourselves we purify our environs. And the corollary follows:

As one lamp lights another nor grows less,  
So nobleness enkindleth nobleness.

## A CASE OF CHRONIC DIARRHŒA ACCOMPANIED BY PYLORIC INSUFFICIENCY;

*Relieved by Hydrochloric Acid.*

By E. PALIER, M. D.,  
New York.

The following case is interesting from several standpoints, and I believe it deserves to be reported:

Patient was a baker, thirty-five years old, born in Russia. He was somewhat above median height and well built. Family history was negative. Patient had had no serious illness, except the one to be described. In April, 1907, he came to me at a dispensary because of a diarrhœa which he said had lasted for the last five years, having had from one to three stools daily. The diarrhœa was painless, and frequently came on soon after a meal, and the patient had also often to get up several times at night to evacuate the bowels. A flesh diet invariably aggravated the trouble, according to patient's statement. He could not give any definite cause to account for his illness.

The patient was pale and anæmic, but there was very little emaciation, contrary to what might be expected. A physical examination showed nothing abnormal, and no points of tenderness could be elucidated anywhere in the

The stools were semiliquid and contained mucus and big pieces of undigested food. What the patient had eaten could be seen in the stools.

The patient was given a test meal at 3 p. m., and in addition he had had a light meal in the morning; the stomach tube was introduced at 4 p. m., i. e., one hour later; but absolutely nothing could be brought out of the stomach. The same was repeated two days later with similar results; the stomach was entirely empty. Then the tube was introduced three quarters of an hour after a test meal, and only a few cubiccentimetres of stomach contents were obtained. The tube was again introduced half an hour after a test meal, and about twenty cubic centimetres of stomach contents were withdrawn. Two days later the same was repeated with similar results.

The stomach contents were not well digested, but it was not surprising in view of the fact that they were withdrawn so soon after the test meal. But there was a moderate reaction on congo paper, and the hydrochloric acid acidity amounted to about 20.

The patient had been put on a strict antidiarrhœal diet, such as rice soup, boiled milk, very soft eggs, etc., and numerous drugs, both singly and in various combinations, had been given, but without any appreciable good results. Opiates had a slight transitory effect only.

The patient was then given dilute hydrochloric acid, 10 drops in a teaspoonful of water, after each meal, and in one week the stools were reduced to two daily, and in another week the patient had about one good evacuation of well formed feces daily, and he said that he felt perfectly well. At first the hydrochloric acid was given together with small doses of bismuth subnitrate and pepsin. But the latter two had been prescribed previously without any effect, consequently no great influence can be attributed to them. Soon, however only the hydrochloric was given. As improvement continued the intervals of exhibiting this drug were gradually increased, till the patient took it only several times during the week. The stomach contents were examined after the patient had improved, and an hour after a test meal the normal amount, about forty to fifty cubic centimetres, could be withdrawn. They were fairly well digested, and the hydrochloric acidity amounted to about 30. On the days when the stomach contents were examined the patient took no hydrochloric acid.

Now, this drug was given the patient at first because I suspected he had some hypochlorhydria; subsequent examinations of the stomach contents, however, showed that the acidity of the patient's stomach was about normal, or at least there was not such a marked deficiency as to require the administration of hydrochloric acid. Nevertheless, the hydrochloric acid had an excellent effect. Whether or not it had a favorable effect on the intestinal secretion, is a question which we cannot answer with any degree of certainty. But there is one thing certain, and that is that the evacuation of the patient's stomach at first was too rapid, and that it became normal under the administration of hydrochloric acid.

Was there pyloric insufficiency or simple hypermotility of the stomach? Seré, and afterwards Epstein, have called attention to pyloric insufficiency. Some authors seem to think, however, that this affection cannot be demonstrated with certainty, and that what is taken for pyloric insufficiency is simply hypermotility of the stomach. It seems to me, however, that if the pylorus functioned well, hypermotility of the stomach alone could not cause the rapid evacuation of the stomach contents, as the pylorus would offer an effective barrier. If there is accelerated evacuation, the pylorus evidently offers an ineffective resistance. In my case the gastric secretion was about normal, and there was no pathological cause to account for a hypermotility of the stomach.

It is very hazardous to draw conclusions from the results of a certain treatment as to the diagnosis, for we know how often such conclusions are de-

ceptive. But in my case it would be hard to explain how the administration of hydrochloric acid could inhibit the hypermotility. But it seems rational to explain that this drug acted on the pylorus as an irritant, causing it to contract longer, and thus causing a longer retention of the food and a better digestion in the stomach, and therefore less work for the intestines.

Such a hypothesis, I am aware, is antagonistic to conclusions recently reached by Cannon<sup>2</sup> from radiographic researches. According to this investigator, the acidity of the stomach has a relaxing effect on the pylorus, and hastens the evacuation of the stomach, whereas diminished acidity is accompanied by retardation of gastric evacuation. This statement is entirely at variance with what we daily see in our patients. People with hypochlorhydria or entire achlorhydria may have a normal or accelerated emptying of the stomach, whereas some who have a high hyperacidity may have, and they frequently do have, retarded evacuation.

A reviewer<sup>3</sup> of Cannon's work, indeed, raises objections to some of the latter's conclusions. These conclusions are certainly in discord with our daily experience.

In my case the passage of undigested food probably acted as an irritant on the intestines, and they in their turn became affected. This case emphasizes the necessity of an examination of the stomach contents in chronic disorders of the alimentary canal. Furthermore, such patients must be warned against taking any liberties with their digestive apparatus, as relapses usually follow abuses. Such patients are relieved, and can remain well as long as they are careful, but they get unwell again under indiscretion in regimen.

55 EAST NINETY-THIRD STREET.

## Therapeutical Notes.

**Furunculosis.**—In the case of a man aged thirty-seven, afflicted with crops of furuncles making their appearance on arms, neck, and body about every two weeks, Shoemaker (*Medical Bulletin*, April, 1908) prescribed rest for a week and an absolute milk diet, beginning the treatment with a thorough purging by means of calomel, gr. ij, in divided doses, powder form, dry, on the tongue every half hour, followed by a tablespoonful of magnesium sulphate in the morning. The following was then ordered to be taken regularly as prescribed:

R	Extract of iron, codina,	gr. i.
	Arsenic trioxide,	gr. i.
	Calcium sulphide,	gr. i.
	Quinine bisulphate,	gr. xlv.
	Extract of gentian,	gr. i.

M. ft. capsule xxx.

Sig. One capsule after each meal and at bedtime.

**Ichthylol and Resorcin Mixture for Dysentery.** Belletre (*Journal de médecine, de Paris*, April 4, 1908) prescribes the following for the treatment of dysentery:

R	Ichthylol,	gr. xlv.
	Resorcin,	gr. i.
	Glycerin,	gr. i.
	Syrup of quince,	gr. v.

M. ft. mist.

Sig.: One tablespoonful three times a day.

(The patient should be instructed to wash out his mouth with water containing a little lemon juice in order to correct the disagreeable flavor of the medicine.)

**Treatment of Vulvovaginitis.**—The various methods of treating inflammation of the vulva and the vagina in children and in adults are collated in Pron's *Formulaire synthétique de médecine*, as follows: For children it is recommended to bathe the vulva twice daily with a 1 in 2,000 solution of potassium permanganate and at the same time inject it into the vagina under light pressure through a small catheter of narrow calibre. At night introduce a pencil shaped pessary of the following:

R	Salol,	gr. i.
	Cacao butter,	gr. xv.

In the case of adults rest in bed should be imposed, and the patient put on a light diet; cold compresses are applied to the vulva, and renewed every two or three hours, tampons of cotton saturated with a 1 in 2,000 solution of potassium permanganate being placed between the labia pudendi majora. Order a Sitz bath with the following:

R	Belladonna leaves,	gr. i.
	Ilyoseyamus leaves,	gr. i.
	Poppy heads,	No. 2.

When the inflammation subsides use once or twice a day at first an injection of boric acid water, and later, potassium permanganate solution (1 in 2,000 to 1 in 1,000); solution of corrosive sublimate, 1 in 5,000, or the following:

R	Copper sulphate,	gr. i.
	Ferrous sulphate,	gr. i.
	Zinc sulphate,	gr. i.
	Gum acacia,	gr. i.
	Water,	gr. i.

M. ft. injection.

Insert between the labia a tampon saturated with an antiseptic or astringent solution, such as a 1 in 200 solution of lead acetate or a 1 in 40 solution of glycerite of tannin.

Folliculitis is treated with a lotion applied lightly as a paint, using either one of the following prescriptions:

I.	R	Silver nitrate,	gr. xii.
		Distilled water,	gr. i.
		Solve.	

II.	R	Zinc chloride,	gr. xii.
		Distilled water,	gr. i.
		Solve.	

As a dusting powder toward the end of the treatment, use the following:

R	Bismuth subnitrate,	gr. i.
	Bismuth subnitrate,	gr. i.
	Zinc oxide,	gr. i.

M.

For chronic vulvovaginitis in children, in addition to the usual tonic treatment (cod liver oil, syrup of iodide of iron, etc.), sea baths should be prescribed, or a bath at home containing

R	Sodium chloride,	lb. ii.
	Sodium carbonate,	gr. i.

M.

<sup>2</sup>Cannon. The Acid Control of the Pylorus, *American Journal of Physiology*, November, 1907, p. 388.

<sup>3</sup>M. P. Langhans, *La Presse médicale*, January 4, 1908.

**Gargle in Diphtheria.**—The following is credited to Heindl, of Vienna, in *Journal de médecine de Paris*, for April 18th:

R Iodine tribromide, .....gtt. xvj;  
Potassium iodide, .....gr. iii;  
Distilled water, .....5x.  
M. ft. gargarisma. Sig.: Use as a gargle every hour.  
(This solution should be put up in an amber colored glass bottle.)

**Suppository for Fissure of the Anus.**—The following suppository will relieve the pain in fissure of the anus:

R Extract of rhatany, .....gr. vi;  
Extract of opium, .....gr. ss;  
Extract of belladonna, .....gr. ½;  
Cocaine hydrochloride, .....gr. ¾;  
Cacao butter, .....gr. xlv.  
M. ft. supposit. i.

Not more than two of these suppositories should be given during twenty-four hours, the susceptibility of some persons to belladonna being borne in mind.

**Treatment of Posttyphoid Alopecia.**—Alfred Martinet discusses in the *Presse médicale*, for April 18th, the loss of hair in women which usually accompanies an attack of typhoid fever, and suggests a course of treatment, remarking that in the case of young girls the æsthetic result of neglect of precautions to insure the regrowth of the hair may prove disastrous to their prospects in life. He considers the question of when the hair should be cut, and advocates cutting it twice, once at the end of the first week after the fever has abated and when the patient is able to bear the exertion entailed by the process, and again a month or six weeks later. The hair should be washed once a week with soap and water or with a decoction of quillaja, and the new growth of hair stimulated by dry friction of the scalp and the application of an invigorating lotion of either of the following types:

I.

R Pilocarpine hydrochloride, .....gr. vi;  
Ammonia water, .....℥ lxxv;  
Spirit of lavender, .....3iss;  
Compound spirit of ether, .....3vi.

M.

II.

R Solution of formaldehyde, .....℥ xv;  
Glacial acetic acid, .....3i;  
Tincture of jaborandi, .....āā 5vi;  
Acetone, .....  
Alcohol, .....āā 3vi.

M.

The last preparation is very active and strongly irritating, and so must be used with caution.

It is noted by Dr. Martinet that the hair is often slow to regain its former vigor, and the patient should be told that it may take six months to restore it, but that recovery is certain, and the new growth will be full and lasting.

[It may be well to repeat here what was said in an editorial article in the issue of the *Journal* for January 4, 1908, on page 29, regarding a prescription of Sabouraud's for falling of the hair in women, in which it was remarked that the proportions of the ingredients in the formula should be varied to suit individual cases, it being observed that

"when a woman finds a particular prescription proves beneficial in her case, she is very apt, in the goodness of her heart, to pass it around among her friends, but disappointment is almost sure to result, because hardly any two cases in the circle of her acquaintances are exactly alike, and it would be as futile to order one prescription for indiscriminate use as to prescribe the same eyeglasses for all persons with visual errors."]

**For Colicky Pain in the Stomach** the following mixture is recommended in *Bulletin général de thérapeutique*:

R Cocaine hydrochloride, .....gr. ¾;  
Codaine, .....gr. ¾;  
Lime water, .....5v;  
Chloroform water, .....3x.

M. Sig.: One tablespoonful every half hour, but not more than four such doses to be administered in one day.

**Mercurial Stomatitis.**—Queyrat is of the opinion that the disagreeable effects sometimes observed to follow hypodermatic injections of mercurial oil are the result of faulty technique. For his part he never injects more than one grain of mercury a week in a patient weighing 145 pounds. He prescribes for use as an application to the teeth and gums during the time the patient is under treatment the following saponaceous dentifrice:

R Almond soap, .....3x;  
Glycerin, .....3vi;  
Extract of rhatany, .....  
Sodium borate, .....āā gr. xx;  
Oil of anise, .....℥ xx;  
Oil of peppermint, .....℥ vi.

Queyrat insists that the treatment should be suspended on the appearance of nodules at the site of injection. In a case of very severe stomatitis following the careless administration of mercury hypodermatically he was able to afford relief to the subject with irrigations of carbolic water and solution of hydrogen dioxide, touching the spots with tincture of iodine and injections of colloidal platinum and sea water.

**Injection for Hæmorrhoidal Pruritus.**—Adler (*Journal de médecine de Paris*, April 18th) uses the following injection:

R Fluidextract of hamamelis, .....3iv;  
Fluidextract of ergot, .....  
Fluidextract of hydrastis, .....āā 3ii;  
Carbolated olive oil (5 per cent.), .....3v.

M. S.: After shaking well, inject one or two ounces into the rectum.

**Intestinal Antiseptic for Children.**—For a child, five years of age, the following is prescribed:

R Bismuth subgallate, .....gr. ¾;  
Sodium bicarbonate, .....gr. iss;  
Prepared chalk, .....gr. lss.  
M. Sig.: One powder every three hours.

**Coryza.**—One or two days' treatment with the following will relieve a cold in the head, says the *Bulletin général de thérapeutique*, for April 8, 1908:

R Atropine sulphate, .....gr. 1/13;  
Pulverized pulsatilla, .....gr. iii;  
Acetyl salicylic acid, .....  
Quinine hydrochloride, } .....āā gr. xxx.  
Sugar of milk, }

M. In cachet xii eq. div.

Sig.: One cachet three or four times a day, at least one hour apart.

## SUBSCRIPTION PRICE:

Under Domestic Postage Rates, \$5; under Foreign Postage Rate,  
\$7; single copies, fifteen cents.

Remittances should be made by New York Exchange or post  
office or express money order payable to the A. R. Elliott Pub-  
lishing Co., or by registered mail, as the publishers are not  
responsible for money sent by unregistered mail.

Entered at the Post Office at New York and admitted for  
transportation through the mail as second class matter.

NEW YORK, SATURDAY, MAY 17, 1908.

## THE HOME MANAGEMENT OF CONSUMPTION AMONG THE POOR.

The city of New York is commonly regarded as furnishing an exceptional example of overcrowding of the poor in unsavory tenements, but perhaps it is by reason of the great population of New York that it has excited so much attention, for it certainly seems as if some smaller municipalities might be held up as at least proportionately equal to us in neglect of domiciliary sanitation. The city of Nantes, for instance, appears to be in very bad condition, as we gather from articles by Dr. Bécigneul and Dr. Fargues, published in the *Gazette médicale de Nantes* for April 11th. Dr. Bécigneul, who reports upon the operations of the *Dispensaire antituberculeux* for the year 1907, is able to record a slightly diminished tuberculous mortality for the year in proportion to the entire number of deaths, though the actual mortality from tuberculous disease was greater than it had been before for more than twenty years. In New York we have made a better showing, but our tenement house population is still atrociously housed.

We suppose it may fairly be presumed that in the matter of habitations for the poor Nantes is no more negligent than many another town of moderate size, though some of the conditions set forth by the authors whose names we have mentioned are about as bad as they could be. For example, it was found in the dispensary visitations that, of sixty-seven families of four members each, one occupied

four rooms, six three rooms (one of them in three instances without a window), thirty-two two rooms (one without a window in four cases), and twenty-eight but a single room. Filth, including excrement, accumulated on the common staircase (which it seemed to be nobody's business to clean), together with repulsive drains sometimes regurgitating the sewer contents to the very verge of a bed, added to the horrors and dangers of the cramped air space.

When the management of a case of pulmonary tuberculous disease at the sufferer's own home is undertaken, the work necessary is not confined to ministering to the individual needs of the sick person; it includes the utmost endeavors to prevent the conveyance of the disease to others. When these efforts are hampered by such conditions as those of Nantes, where often as many as four persons had to sleep in one bed, there is scant hope of forestalling infection. It must be evident to the most superficial student of demography that the housing of the poor needs radical improvement if we are to better the public health in any considerable degree.

## THE "ADRENOTHYREOID CENTRE"

By this term, as used by Dr. Charles E. de M. Sajous, of Philadelphia, we understand the pituitary body or some constituent part of that structure, acting through direct nerve connections upon the thyroid and the suprarenal glands. A notable contribution to our conceptions of its action is to be found in a paper recently presented by Dr. Sajous before the American Therapeutic Society and the Philadelphia Branch of the American Pharmaceutical Association. It is entitled *The Autoprotective Resources of the Body—A New Foundation for Scientific Therapeutics*. It is to appear in full in the May number of the *Monthly Cyclopædia of Practical Medicine*, advance sheets of which have been courteously sent to us.

The pituitary body, if we understand Dr. Sajous aright, performs the twofold duty of a sentry (being in great part a sensory organ) and of an aide de camp, calling the thyroid or the suprarenals into defensive action when it has scented danger to the organism. It is on this associated function of defense, fulfilled by what he terms the "adrenal system," that Dr. Sajous thinks that the therapeutics of the future—scientific therapeutics—must largely be founded. The therapeutics of the present time rests extensively on empiricism, and empirical knowledge, as he, in common with many other thoughtful writers, freely admits, always constitutes the cornerstone of a science. It is doubtful, indeed, whether we shall ever wholly escape from empiricism; perhaps it is in no great degree desir-

able that we should do so, and certainly we ought not to seek to break loose from it violently at the expense of what is useful, even if not entirely explicable. This Dr. Sajous freely concedes, but he is none the less mindful of the superiority of a system of therapeutics founded on coordinated facts and susceptible of a rational explanation.

Since Bichat, as it seems to us, there has been no more fascinating projector of a philosophy in medicine than Dr. Sajous. With an enthusiasm bordering on eagerness he leads us on through difficulties at which, left to our own resources, many of us might quail. What will it ultimately matter if he is at length shown not to have paused to struggle with every feature of detail that he encountered? For our part, we prefer his ardent prosecution of a grand idea to the sombre platitudes of the therapeutic nihilist, for it seems reasonably sure to lead to something positive and to help powerfully in lifting into an approach to certainty that feature of medicine which most concerns the community at large and upon the condition of which we must be content to be rated.

#### THE SEASIDE FOR NEURASTHENICS.

In the *Journal de médecine de Bordeaux* for April 12th there is published a portion of a report on this subject prepared by Dr. E. Régis for the Biarritz Congress of Climatotherapy, including the author's conclusions. He remarks that one must take account of the individual's idiosyncrasies, psychical and physical; it is quite important that the seaside should be attractive to the patient. Up to the present time a marine climate has generally been thought to be favorable to depressed persons and injurious to those who are excited, but a reaction against this traditional way of thinking seems now to have set in, and the reverse opinion appears to be justified by observed facts, so that neither excitement nor depression is a formal indication or contraindication of seaside treatment. Apart from idiosyncrasy and other considerations, purely nervous excitation as a manifestation of the neurasthenic condition is benefited, or at least not aggravated, by a marine climate, while seaside treatment is injurious and even dangerous in cerebral excitation due to organic lesions of the nervous system underlying the neurasthenia. Depression, on the other hand, must not be associated with too profound debility.

Unless there is grave intolerance or some subjacent morbid complication, neurasthenia occurring in children and adolescents is notably ameliorated by thalassotherapy, especially if, as is not infrequently the case, there is present retardation of growth, rickets, lymphatism, or spermatorrhoea. All

forms of neurasthenia in females are especially relieved by seaside treatment, preeminently those supervening at puberty or at the menopause and those accompanied by dysmenorrhœa, uterine and ovarian affections, visceral ptoses, anæmia, or general debility. The only contraindications are super-sensitiveness to barometric changes and profound general weakness. Hysteria is no bar to the treatment. Neurasthenia accompanying or closely preceding senility calls for the greatest prudence in prescribing the seaside treatment, on account of the circulatory cerebral derangements with which it is most frequently associated; but there is no absolute contraindication, for certain aged neurasthenics, especially men, are notably benefited by the seaside.

The indications are more dependent on the peculiarities of the individual than on the ætiology of his nervous trouble, or, with certain exceptions, on its clinical form. The marine climate is best adapted to those forms of general neurasthenia in which the asthenic element predominates. Gastrointestinal neurasthenia, especially if it is complicated with mucomembranous enteritis, is injuriously influenced by such a climate. Psychic neurasthenia is under no fixed rule as regards thalassotherapy; in it that treatment is not inadmissible, though delirium, hallucinations, morbid impulses, and epileptic manifestations are more or less prohibitive. The symptomatic neurasthenias, especially the "preorganic," such as those preceding tabes or paralysis, do not usually allow the treatment to be well borne. Opinions differ as to the effects of a marine climate on the nervous system of tuberculous persons, some considering them as sedative, others as excitant.

#### THE TREATMENT OF CANCER OF THE TONGUE IN SYPHILITICS.

In our issue for May 9, 1908, we spoke of the diagnosis of lingual cancer in syphilitic subjects. As regards the treatment, it should be prophylactic, and Hallopeau insisted last year, before the French Academy of Medicine, on the fact that certain types of syphilis should be more actively treated in order to prevent the development of epithelioma. If one is dealing with an initial syphiloma, the growth should be cauterized with acid nitrate of mercury after having been anesthetized. For the leucoplakia, Gaucher and Trapenard advise frequent irrigation of the mouth with alkaline solutions where ulceration is present, but if the latter is absent the diseased structures may be cauterized with a weak solution of potassium bichromate, the excess of the latter being removed by careful irrigation. Cauterization of the fissures should be done with chromic acid or the acid nitrate of mercury, and

when the ulcerations are deep the galvanocautery must be resorted to.

The treatment becomes more delicate when the epithelioma has appeared. Horand is inclined to treat the syphilis with mercury. The iodides may produce oedema and a congestive attack in the cancerous ulceration. On the other hand, mercury has given excellent results with Fournier. Mercury should be administered in the form of subcutaneous injections of calomel, given once a week, five centigrammes in each injection, or with the gray oil, the dose of mercury not being more than seven centigrammes. As soon as the lesions become stationary, and the improvement which in the first place showed itself ceases, the injections are to be stopped. This treatment should not be continued too long, otherwise the epithelioma will become aggravated, and the proper surgical procedures will have to be retarded.

Should a radical operation be declined or prove impossible, medicinal treatment offers as a last resort the use of the hydrobromide or hydrochloride of quinine, in amounts of twenty to thirty grains daily for from fifteen to twenty consecutive days, or in hypodermic or intramuscular injections of a fifty per cent. watery solution. Trypanroth may be given subcutaneously, seven grains dissolved in ten drachms of sterilized salt solution. Four or five injections are to be given, and then one should wait until decolorization of the integument occurs, when one or two more are given. This treatment of carcinoma should always be combined with the use of general tonics.

#### THE ASSOCIATION OF AMERICAN PHYSICIANS.

This year's meeting of the association, held in Washington on Tuesday and Wednesday of this week, was among the most notable gatherings of the organization. There was a large attendance of representative men from various parts of the country, the programme contained titles of many topics of prime importance in the progress of medicine, and the discussions were to the point and free of useless talk. The association, now nearing the completion of its first quarter of a century, has done much to further advancement in our art, and its future course may assuredly be looked for for further solid work.

#### FLIES AND MOSQUITOES

The suburban householder is now engaged in taking down his storm windows and putting up his Venetian blinds, preparing to let in the warm airs of summer and keep out the glare of the sun. It is happily coming to be more and more recognized that

an important part of the spring attire of the house is the installation of window screens for the exclusion of flies and other insects. A study of statistics shows a rapid rise in the morbidity of infectious febrile diseases coincident with the advent of the fly and the mosquito, and the householder who adequately protects his house against the visits of these little pests goes a long way toward insuring himself and his family against these infectious diseases. The mosquito is so obnoxious for its immediate effect, the annoyance of its song and of its sting, that much more effort is put forth to destroy it or to protect the household from its effects than is exerted for the purpose of ridding the house of the fly. While the mosquito is the bearer of at least two specific infectious diseases, malarial fever and yellow fever, the fly is known to be mechanically the bearer of a wide variety of infectious diseases, one of the most dangerous of which is typhoid fever. It is quite probable that many of the cases of typhoid fever, the origin of which cannot be traced, are due to infection through the agency of flies, and the housekeeper who keeps her house free from these pests confers a double benefit on her household in promoting cleanliness and the health of its members.

#### INCREASED PAY FOR THE ARMY MEDICAL OFFICER.

The combination of advanced rank given under the measure reorganizing the medical corps of the Army, which was printed in our issue of April 18th, and of increased pay under the Army appropriation bill, which has just been agreed to by Congress, will, it is hoped, make the medical corps so much more attractive to the younger members of the profession that it may be possible to fill the vacancies in the corps and thus furnish a force more nearly commensurate with the tasks confronting this department of the Army.

The increase in pay provided for in the appropriation bill is well deserved, and is far from being liberal when the increased cost of living is taken into consideration. The present pay tables were adopted many years ago, and a comparison of the cost of living then and now would show an increase of probably  $33\frac{1}{3}$  per cent. Recent studies prove that during the past ten years alone there has been an increase of 25 per cent. in the cost of living. In order, therefore, to place the income of the Army officer on a parity with that which he was receiving 20 years ago, taking the cost of living into consideration, his pay should have been increased 25 per cent. This has not been done in the appropriation bill, save in the case of the first lieutenant, who is therefore relatively better off than his superior officers.

cers. The increase provided in the appropriation bill amounts approximately to 20 per cent. for the captain and major, 16 per cent. for the lieutenant colonel, 14 per cent. for the colonel, and 9 per cent. for the brigadier general. It will thus be seen that, taking the increased cost of living into consideration, Congress has not been unduly liberal to Army officers in the matter of pay.

## DERMATOLOGY AND KNIGHTHOOD.

We learn from an editorial article in the April number of the *British Journal of Dermatology* that on March 19th a complimentary dinner was given in London to Sir Malcolm Morris, to congratulate him on the honor recently conferred upon him by the King. The chairman, Dr. H. Radcliffe-Crocker, president of the Dermatological Section of the Royal Society of Medicine, the article goes on to say, pointed out that this was the first time that a title had been given to a dermatologist "in recognition of services rendered in that special branch of medicine." Would it not have been just as well to allow certain people to keep on taking it for granted that the late Sir Erasmus Wilson owed his title to his achievements in dermatology?

## News Items.

**Changes of Address.**—Dr. William Rumfitt Lee, of the New York Lying-in Hospital, New York, to 342 Second street, Troy, N. Y.; Dr. H. Greenstein, to 341 East Fifty-second street, New York.

**The Gloucester County, N. J., Medical Society** will meet in Woodbury, N. J., on Thursday, May 21st, at 2:30 p. m. The principal feature of the programme will be a paper by Professor Orville Horwitz.

**A Department of Psychology at Chautauqua.**—Arrangements have been made for a department of psychology at Chautauqua, N. Y., this summer, and Professor Charles H. Judd, of Yale, will be one of the lecturers.

**The Portland, Me., Medical Club** met on Thursday, May 7. Dr. John F. Thompson was the host, and Dr. George N. Turner was the essayist of the evening, the subject of his paper being Psoriasis.

**Rochester, N. Y., Academy of Medicine.**—At a regular meeting of this academy, which was held on the evening of May 13th, Dr. E. Wood Ruggles read a paper entitled Honor to Whom Honor Is Due—a Tribute to the Late Dr. Henry Koch.

**New York Academy of Medicine.**—At a meeting of the Section in Laryngology, which will be held on Saturday, May 23d, at 8:15 p. m., Dr. Albert Jansen, of Berlin, Germany, will read a paper on Frontal Sinus Disease. Members of the academy and their guests are invited.

**National Association for the Study and Prevention of Tuberculosis.**—The fourth annual meeting of this association will be held at the Auditorium Hotel, Chicago, on June 5th and 6th. An extensive program has been arranged, and the meeting promises to be both interesting and profitable.

**Medical Society of the County of Kings, N. Y.**—A meeting of the Section in Pediatrics was held on Friday evening, May 15th. Dr. H. B. Wilcox, of Manhattan, read a paper entitled Diabetes Mellitus in Infants and Young Children, and Dr. G. F. Little, of Brooklyn, read a paper on the Marantic Infant.

**Summer Session of the University of Michigan.**—The annual summer session of the department of medicine and surgery of the University of Michigan will open on June 22d and close on July 31st. The course is open to all persons qualified to pursue it to advantage, and no formal requirements for admission are exacted.

**More Pay for the Naval Officer.**—Naval surgeons will be interested to learn that on May 12th the House of Representatives adopted the conference report on the Senate amendments to the naval appropriation bill, the effect of which will be to increase the pay in the Navy and the Marine Corps and of officers on the retired list.

**The Birth Rate of France.**—Vital statistics for the year 1907 show a marked decrease in the number of births in France. During the year there were 774,000 births recorded, which was 33,000 less than for the preceding year, while the average decrease for the past seven years has been 12,000. There were 793,000 deaths during the year.

**A Summer Course in Medicine at the St. Louis University.**—A summer course in medicine, beginning May 25th and ending July 4th, has been arranged by the St. Louis University. It is intended for both students and practitioners of medicine, and instructors have been engaged who will deliver lectures on the various branches of medicine.

**Contagious Diseases in Chicago.**—During the week ending May 2, 1908, there were reported to the Department of Health 517 cases of contagious diseases, as follows: Diphtheria, 59; scarlet fever, 75; smallpox, 4; measles, 281; chickenpox, 23; typhoid fever, 18; whooping cough, 11; tuberculosis, 39; minor contagious diseases, 7.

**Connecticut River Valley Medical Association.**—At the annual meeting of this association, held in Bellows Falls, Vt., on May 5th, the following officers were elected: President, Dr. J. A. Stevenson, of Chester; vice president, Dr. O. L. Corliss, of Walpole, N. H.; secretary, Dr. J. S. Hill, of Bellows Falls; treasurer, Dr. Edward R. Campbell, of Bellows Falls.

**Medical Society of the Missouri Valley.**—The annual dinner of the society will be given at the Victoria Hotel, Chicago, on Wednesday, June 3d, at 6 p. m. Tickets may be obtained from the secretary at the hotel. Ladies are invited. On June 5th there will be an excursion to Milwaukee, where the party will be entertained by Dr. C. O. Thienhaus.

**The Medical Society of Richmond County, N. Y.**—The regular monthly meeting of this society was held at the Staten Island Academy of Medicine on the evening of May 13th. Dr. W. R. Bastedo, of Manhattan, read a paper entitled Gastrointestinal Diseases from an Everyday Standpoint, which was discussed by Dr. George Mord and Dr. Goodwin.

**Buffalo Academy of Medicine.**—At a meeting of the Section in Medicine, which was held on May 12th, the general subject for discussion was bacterial vaccines, papers being read as follows: The Vaccines in Their Application to the Ordinary Pyogenic Case, by Dr. Norman K. MacLean; The Vaccines in Their Relation to Erysipelas, by Dr. Thomas J. Walsh.

**The Society of Medical Jurisprudence, New York.**—At the two hundred and fourteenth regular meeting of this society, which was held at the New York Academy of Medicine on the evening of May 11th, Dr. Thomas Darlington, Health Commissioner of the City of New York, read a paper entitled Food and Drug Adulterations; Their Medical and Legal Significance.

**Richmond, Va., Academy of Medicine and Surgery.**—A meeting of this academy was held on May 12th. Dr. Edward McGuire read a paper on Prolapse of the Ovary, which was discussed by Dr. R. D. Garcin. The Technique of Operations on the Mouth and Neck was the title of a paper read by Dr. J. Shelton Horsley. The discussion on this paper was opened by Dr. J. W. Henson.

**The Bristol, Mass., South District Medical Society.**—The annual meeting of this society was held on Thursday afternoon, May 14th. The general subject for consideration was prostatic hypertrophy. Dr. H. C. Allen read a paper on the pathology of the disease, Dr. A. I. Connell dealt with the question of palliative treatment, and surgical treatment was the subject of a paper by Dr. G. de N. Hough.

**A Special Number of the Women's Medical Journal** has been issued with the report of the annual meeting of the Women's Medical Society of the State of New York. The number contains several interesting communications, a handsome portrait of Dr. Sarah Adamson Dolley, of Rochester, president of the Women's Medical Society of the State of New York, and an appreciative editorial notice of Dr. Dolley and her work.

**Personal.**—Dr. Frank K. Sanders, of Boston, has been appointed president of Washburn College, Topeka, Kan.

Dr. George H. M. Rowe, for twenty-nine years superintendent of the Boston City Hospital, has been obliged to give up his position on account of ill health. The trustees of the hospital have given him an indefinite leave of absence. Dr. J. H. McCullom has been appointed head of the hospital during Dr. Rowe's absence.

On May 19th the alumni of the medical department of Tulane University, New Orleans, will celebrate Dr. S. E. Chaillé's fiftieth anniversary as a teacher in the department.

**The Medical Society of the Borough of the Bronx.**—At a stated meeting of this society, held on the evening of May 13th, the following papers were read: Rupture of the Kidney, by Dr. Joseph J. Higgins; Some Observations of the Juvenile Delinquent from a Medical Standpoint, by Dr. William G. Eynon; The Management and Care of Patients with Hemiplegia resulting from Cerebral Apoplexy, by Dr. William M. Leszynsky.

The Annual Meeting of the National Conference of Jewish Charities was held in Richmond, Va., recently. On the last day of the conference the following officers were elected for the ensuing year: President, Dr. Jacob H. Hollander, of Baltimore; first vice president, Mr. Martin A. Marks, of Cleveland; second vice president, Mrs. Max Lowenberg, of New York; secretary, Mr. Louis Lavine, of Baltimore; treasurer, Mr. Bernard Greensfelder, of St. Louis.

**American Surgical Association.**—At the annual meeting of this association, which was held recently in Richmond, Va., the following officers were elected for the ensuing year: President, Dr. C. B. G. Nancrede, of Ann Arbor, Mich.; vice presidents, Dr. A. P. Gerster, of New York, and Dr. Leonard Freeman, of Denver; treasurer, Dr. Charles A. Powers, of Denver; secretary, Dr. Robert G. Leconte, of Philadelphia. The meeting in 1909 will be held in Philadelphia.

**Medical Society of the Woman's Hospital of Philadelphia.**—At a meeting held on Monday evening, April 20th, the following programme was presented: Demonstration of the venous pulse, by Dr. Frances C. Van Gasken and Dr. Anne H. Thomas; a paper on Laryngeal Complications of Typhoid Fever, by Dr. Emma E. Musson; the report of Septic Cases following Childbirth, by Dr. Caroline M. Purnell; and a paper entitled Technique of the Ophthalmoculiculin Reaction, by Dr. Mary C. McClellan.

**College of Physicians, Philadelphia.**—The following programme was presented at a meeting of the Section in Medical History, which was held on Tuesday evening, April 28th: Some Remarks about Dr. Lettsom, by Dr. Charles J. Burr; The State of Medicine as Depicted by Pepys in the Reign of Charles II; Montaigne's Estimate of the Medical Profession, by Dr. Francis B. Packard; the exhibition of a Pharmacopoeia formerly the property of William Penn, by Professor Joseph P. Remington.

**The Philadelphia Academy of Surgery.**—At a meeting of the Academy, held on Monday evening, May 11th, the following papers were read: *A Case of Hemorrhoids*, by J. S. Transfusion, by Dr. Francis O. Allen; *Two Cases of Intestinal Hemorrhage following Abdominal Operation*, by Dr. Charles F. Mitchell; *A Case of Gastrointestinal Hemorrhage following Radical Operation for Hernia*, by Dr. J. S. Transfusion; *A Specimen of Large Fibrosarcoma of the Uterus, Complicated by a Three Months' Pregnancy*, by Dr. Joseph Horowitz.

**American Gynecological Society.**—The thirty-third annual meeting of this society will be held at the Hotel Marlborough, Philadelphia, on May 29th and 30th. All the members are invited to the Anniversary Hall of the College of Physicians. The officers of the society are: President, Dr. J. Mayhew, Philadelphia; President-elect, Dr. J. Mayhew, Philadelphia; Vice-presidents, Dr. J. Mayhew, Philadelphia; Secretary, Dr. J. Mayhew, Philadelphia; Treasurer, Dr. J. Mayhew, Philadelphia; and Executive Committee, Dr. J. Mayhew, Philadelphia.

**Officers of the American Therapeutic Society.**—At the annual meeting of the society, which was held in Philadelphia last week, the following officers were elected: President, Dr. Frederic H. Gerrish, of Portland, Me.; first vice president, Dr. Alexander D. Blackader, of Montreal, Canada; second vice president, Dr. Howard Van Rensselaer, of Albany, N. Y.; third vice president, Dr. Robert T. Morris, of New York; secretary, Dr. Noble P. Barnes, of Washington, D. C.; treasurer, Dr. A. Ernest Gallant, of New York.

**The Medical Society of Washington County, Md.**, met in regular session on Thursday, May 14th. Dr. E. Tracy Smith read a paper on Parasites, and Dr. Clara S. Carley presented the report of a clinical case. The reading of the papers was followed by a general discussion of the relations at present existing between the society and the Washington County Hospital Association. The value of the post graduate course was considered, and the question of physicians' names appearing in the public press in connection with notices of their cases was discussed.

**The Medical Association of the Greater City of New York.**—A stated meeting of this association will be held in Du Bois Hall, New York Academy of Medicine, on Monday, May 18th, at 8:30 p. m. The programme includes the following: Remarks on the Ultraviolet Ray, High Frequency Currents, and Tabes, suggested by the discussion at the March meeting, by Dr. Henry G. Piffard; a paper by Dr. Edward F. Brush, entitled Dairy Dirt (Harmful Dirt; Harmless Dirt; Pathological Dirt; Aesthetic Dirt; Some New Points Relative to Typhoid Fever and Milk); a paper on Diseases Conveyed by Insects, by Dr. John B. Huber.

**Vital Statistics of the Philippines.**—According to the *Quarterly Report of the Bureau of Health of the Philippine Islands*, during the last quarter of the year 1907 the number of deaths registered was 2,502, corresponding to an annual death rate of 44.42 in 1,000 of population, which is somewhat higher than that of the other three quarters of the year. The report shows an increase in the number of deaths from bronchitis, pneumonia, and cholera, but a slight decrease in the number of deaths due to diseases of the alimentary canal. There were 2,293 births registered during the quarter, an increase of 310 over the preceding quarter.

**The Mortality of Chicago.**—According to the bulletin of the Department of Health, for the week ending May 7, 1908, there were during the week 536 deaths from all causes, as compared with 764 for the corresponding period in 1907. The annual death rate in 1,000 of population was 12.90. The principal causes of death were: Apoplexy, 10; Bright's disease, 28; bronchitis, 22; consumption, 67; cancer, 29; convulsions, 5; diphtheria, 10; heart diseases, 54; influenza, 3; intestinal diseases, acute, 32; measles, 2; nervous diseases, 20; pneumonia, 68; scarlet fever, 4; suicide, 9; violence (other than suicide); whooping cough, 1; all other causes, 141.

**Vital Statistics of New York.**—During the week ending May 2, 1908, there were reported to the Department of Health 7,562 deaths from all causes, corresponding to an annual death rate of 17.60 in 1,000 of population. Of the total number of deaths, 888 were in Manhattan, 88 in the Bronx, 479 in Brooklyn, 65 in Queens, and 20 in Richmond. The principal causes of death were: Contagious diseases, 154; pulmonary tuberculosis, 178; pneumonia, 271; organic heart disease, 145; cancer, 62; apoplexy, 100; infectious diseases (under five years of age), 54; suicide, 20; homicide, 2; accidents, 73. There were 151 still births. The number of births recorded during the week was 23,700, and

## Infectious Diseases in New York:

It is suggested to use strong evidence in favor of the treatment of choice in the following treatment of new cases and double selection for the new double cases. The

**Scientific Society Meetings in Philadelphia for the Week Ending May 23, 1908.**—*Monday, May 18th*, North-east Branch, Philadelphia County Medical Society. *Tuesday, May 19th*, Dermatological Society; Academy of Natural Sciences; North Branch, Philadelphia County Medical Society. *Wednesday, May 20th*, Section in Otology and Laryngology, College of Physicians; Association of Clinical Assistants, Wills Hospital; Franklin Institute. *Thursday, May 21st*, Section in Gynecology, College of Physicians; Section meeting, Franklin Institute; Medical Society, Woman's Hospital. *Friday, May 22d*, South Branch, Philadelphia County Medical Society; Northern Medical Association; Philadelphia Neurological Society.

**Philadelphia Polyclinic and College for Graduates in Medicine.**—The following are registered at this college: Dr. N. P. Wood, of Denver, Col.; Dr. W. B. Kearney, of San Francisco, Cal.; Dr. G. C. Snyder, of Moxahala, Ohio; Dr. T. C. Bakes, of Katon, N. M.; Dr. James M. Blackwood, of New Castle, Pa.; Dr. S. Ira McDowell, of Dallastown, Pa.; Dr. L. A. Larson, of Kane, Pa.; Dr. E. H. Hickman, of Kane, Pa.; Dr. Douglas F. A. Jacoby, of Newport, R. I.; Dr. John Lear, of Allentown, Pa.; Dr. Henry F. Schwartz, of Reading, Pa.; Dr. J. C. McAllister, of Ridgway, Pa.; Dr. Norman H. Goodenow, of North Yakima, Wash.; Dr. A. J. Hill, of Canton, Ohio; Dr. Herman D. Andrews, of Buffalo, N. Y.; Dr. H. Wells Woodward, of Washington, D. C.; Dr. H. W. Cowper, of Buffalo, N. Y.; Dr. W. E. McLoughlin, of Minneapolis, Minn.; Dr. Charles H. Brown, of Franklin, Pa.; Dr. J. H. Orison, of Lahore, India, and Dr. R. D. Nicholls, of Glassport, Pa.

**The Health of the Canal Zone.**—During the month of March there were 198 deaths in the Canal Zone, including the cities of Panama and Colon, in a population of 114,920, corresponding to an annual death rate of 20.67 in 1,000 of population. There was 1 death from typhoid fever, 6 from zestivoautumnal malaria; 18 from clinical malaria; 1 from malarial cachexia; 1 from haemoglobinuric fever; 3 from amoebic dysentery; 1 from clinical dysentery; 3 from beriberi; 2 from purulent infection and septicaemia; 17 from tuberculosis of the lungs; 5 from other forms of tuberculosis; 3 from tetanus; 9 from bronchopneumonia; 13 from pneumonia; and 11 from diarrhoea and enteritis, under two years of age. The death rate among the white employees of the commission was 16.75 in 1,000; among the black employees, 10.80 in 1,000; and among all the employees, 12.47 in 1,000. The morbidity rate among all employees was 18.23 in 1,000 of population.

**Charitable Bequests and Donations.**—By the will of Joseph Channon the Bethesda Children's Home, the Children's Hospital, the Episcopal Hospital, the Foster Home, the German Hospital, the Germantown Hospital, the Germantown Relief Society, the Orphan's Home and Asylum for the Aged of the Lutheran Church, Germantown, the Masonic Home of Pennsylvania, the Methodist Episcopal Home for the Aged, the Methodist Episcopal Hospital, the Methodist Episcopal Orphanage, the Odd Fellows' Home, the Samaritan Hospital, the Southern Home for Destitute Children, and the Woman's Hospital, of Philadelphia, became reversionary legatees.

By the will of John A. Brill, the German Hospital, Hayes Mechanics' Home, the Society for Organizing Charities, and the Free Hospital for Poor Consumptives (Whitehaven Sanitarium) receive \$5,000 each; the Home for Incurables receives \$3,000, and the Home for Crippled Children receives \$2,000.

Lord Strathcona and Lord Mount Stephen have each donated the sum of \$1,000 to the General Hospital of Winnipeg, Canada.

The estate of the late Mrs. Thomas T. Kinney has made a gift of \$10,000 to the Babies' Hospital, Newark, N. J., as an endowment fund.

The board of directors of the Whitehaven Sanitarium for consumptives announces the gift of a new cottage, with a capacity of sixteen beds, by Mrs. Henry Phipps, of Pittsburgh.

**The Health of Pittsburgh.**—During the week ending April 18, 1908, the following cases of transmissible diseases were reported to the Bureau of Health of Pittsburgh: Chickenpox, 12 cases, 0 deaths; typhoid fever, 26 cases, 6 deaths; scarlet fever, 13 cases, 1 death; diphtheria, 8 cases, 3 deaths; measles, 191 cases, 10 deaths; whooping cough, 8 cases, 1 death; pulmonary tuberculosis, 20 cases, 11 deaths. The total deaths for the week numbered 160 in an estimated population of 403,330, corresponding to an annual

death rate of 20.62 in 1,000 of population. During the week ending April 25, 1908, the following cases of transmissible diseases were reported: Chickenpox, 7 cases, 0 deaths; typhoid fever, 29 cases, 2 deaths; scarlet fever, 21 cases, 2 deaths; diphtheria, 8 cases, 3 deaths; measles, 252 cases, 6 deaths; whooping cough, 26 cases, 2 deaths; pulmonary tuberculosis, 10 cases, 10 deaths. The total deaths for the week numbered 192, in an estimated population of 403,330, corresponding to an annual death rate of 24.75 in 1,000 of population.

**The Health of Philadelphia.**—During the week ending, April 25, 1908, the following cases of transmissible diseases were reported to the Bureau of Health of Philadelphia: Typhoid fever, 95 cases, 13 deaths; scarlet fever, 52 cases, 6 deaths; chickenpox, 41 cases, 0 deaths; diphtheria, 54 cases, 9 deaths; cerebrospinal meningitis, 1 case, 0 deaths; measles, 508 cases, 10 deaths; whooping cough, 38 cases, 1 death; pulmonary tuberculosis, 109 cases, 56 deaths; pneumonia, 80 cases, 56 deaths; erysipelas, 10 cases, 0 deaths; puerperal fever, 5 cases, 2 deaths; mumps, 33 cases, 0 deaths; cancer, 23 cases, 25 deaths; tetanus, 1 case, 1 death. The following deaths were reported from other transmissible diseases: Tuberculosis, other than tuberculosis of the lungs, 14; diarrhoea and enteritis, under two years of age, 11. The total deaths for the week numbered 499 in an estimated population of 1,532,738, corresponding to an annual death rate of 16.90 in 1,000 of population. The total infant mortality was 111; under one year of age, 75; between one and two years of age, 36. There were 39 still births; 20 males, and 19 females.

**American Protogological Society.**—The tenth annual meeting of this society will be held in Chicago, June 1st and 2d. The preliminary programme, which we have just received, includes a long list of papers by well known specialists in diseases of the rectum, among whom are the following: Dr. William M. Beach, of Pittsburgh, Pa.; Dr. John L. Jelks, of Memphis, Tenn.; Dr. Samuel T. Earle, of Baltimore; Dr. Samuel G. Gant, of New York; Dr. Joseph M. Mathews, of Louisville, Ky.; Dr. William L. Dickinson, of Saginaw, Mich.; Dr. Jerome M. Lynch, of New York; Dr. J. A. MacMillan, of Detroit; Dr. T. C. Hill, of Boston; Dr. Collier F. Martin, of Philadelphia; Dr. George B. Evans, of Dayton, Ohio; Dr. Dwight H. Murray, of Syracuse, N. Y.; Dr. James P. Tuttle, of New York; Dr. Louis J. Hirschman, of Detroit; Dr. J. Rawson Pennington, of Chicago; Dr. Louis J. Krouse, of Cincinnati; Dr. Edwin A. Hamilton, of Columbus, Ohio; Dr. B. Merrill Ricketts, of Cincinnati; Dr. Leon Straus, of St. Louis; and Dr. Lewis H. Adler, Jr., of Philadelphia. The officers of the society are: President, Dr. A. Bennett Cooke, of Nashville, Tenn.; vice president, Dr. Louis J. Krouse, of Cincinnati, Ohio; secretary and treasurer, Dr. Lewis H. Adler, Jr., of Philadelphia.

**The Army Pay Bill and the Officers of the Medical Corps.**—The Army appropriation bill which provides for the pay of officers and men of the Army has, after various amendments, been at last agreed to by a conference committee of the Senate and the House of Representatives. The report of the conference committee has been accepted and it is quite probable that the measure will be signed by the President in the near future. In our issue of April 18th we printed the text of the measure providing for the reorganization of the Army Medical Department, which changes the title of the department to Medical Corps, drops the titles of surgeon, assistant surgeon, etc., and leaves the officers of the corps to be designated simply by their military titles. This measure also provides for a material increase in the number of the officers in the corps and for the establishment of a reserve medical corps. The appropriation bill as finally adopted provides for a flat increase of \$500 a year in the salary of officers, save that the increase in the pay of the first lieutenant and captain is only \$400. The measure also provides for an increase in the pay of enlisted men and noncommissioned officers of the hospital corps, and specifically provides against the use of this rate of pay as a basis on which to compute the pay of naval officers.

**Clinical Week at Boston University.**—In response to many requests from physicians throughout New England, the faculty of the Medical School of Boston University has arranged for a short course of general clinical instruction. This course will be held during commencement week, June 1 to 6, 1908. The sessions will begin daily at 9 a. m. and continue till 4 p. m., the entire time being fully occupied by clinics, clinical lectures, lectures and demonstra-

tions. More than thirty professors and lecturers will participate, each dealing with the particular subject in his own line that he considers of most general value. General medicine, surgery, gynecology, and the various specialties will all be represented, as well as other miscellaneous subjects. The course will be so arranged that each attendant can be present at every exercise and can thus obtain a survey of a large field in a comparatively short time. Sessions will be held at the Medical School buildings, at the Out Patient Department of the Hospital, and in the amphitheatre and the clinical lecture room of the main building of the hospital. Free use will be made of the large amount of clinical material available in these closely connected institutions, as well as that from other sources. The course will be open without fee to graduates of any reputable medical college. The number admitted will be limited, tickets being issued in the order of application. Further information and tickets admitting to all sessions may be obtained from the registrar, Dr. Frank C. Richardson, 80 East Concord street, Boston.

**Philadelphia County Medical Society.**—A meeting of the West Branch of this society was held on Friday evening, May 15th. The guest of the evening was Dr. Theodore B. Appel, of Lancaster, Pa., who read a paper entitled Lancaster County and Its People and the Practice of Medicine Therein. The paper gave a historical sketch of the people of the county, describing some of their characteristics and the difficulties the medical man meets in practicing among them. Dr. Julius F. Sachse also contributed some historical notes on medical practice in Lancaster County. Dr. A. B. Hirsh exhibited a copy of the manual of practice of the hydropathic institution that existed at Ephrata Springs early in the last century, and related some of the experiences of medical students in Lancaster County. Dr. Samuel Skillern read a paper entitled Reminiscences of the Practice of Medicine in the Early Days of Western Philadelphia. Dr. Charles W. Dulles opened the discussion on this paper.

At a meeting of the Central Branch of this Society, which was held on Wednesday, May 13th, the evening was devoted to a "symposium" on lateral curvature. Dr. James K. Young presented patients who had been cured of lateral curvature by light gymnastics and selective exercises. Dr. H. O. Feiss, of Cleveland, Ohio, read a paper on the Mechanism of Lateral Curvature. Dr. H. Augustus Wilson exhibited lantern slides showing faulty postures in school children which produce lateral curvature. Dr. Harry Hudson demonstrated his new scolometer. Among those who took part in the discussion were Dr. de Forrest Willard, Dr. James P. Mann, and Dr. J. Torrance Rugh.

#### Society Meetings for the Coming Week:

**Monday, May 18th.**—New York Academy of Medicine (Section in Ophthalmology); Medical Association of the Greater City of New York; Hartford, Conn., Medical Society.

**Tuesday, May 19th.**—New York Academy of Medicine (Section in Medicine); Medical Society of the County of Westchester, N. Y.; Buffalo Academy of Medicine (Section in Pathology); Tri-Professional Medical Society of New York; Medical Society of the County of Kings, N. Y.; Binghamton, N. Y., Academy of Medicine; Clinical Society of the Elizabeth, N. J., General Hospital; Syracuse, N. Y., Academy of Medicine; Ogdensburg, N. Y., Medical Association.

**Wednesday, May 20th.**—New York Academy of Medicine (Section in Genitourinary Diseases); New York Society of Dermatology and Genitourinary Surgery; Woman's Medical Association of New York City (New York Academy of Medicine, annual); Medical-Legal Society, New York; New Jersey Academy of Medicine (Jersey City); Buffalo Medical Club (annual); New Haven, Conn., Medical Association; New York Society of Internal Medicine; Northwestern Medical and Surgical Society of New York.

**Thursday, May 21st.**—New York Academy of Medicine; German Medical Society, Brooklyn; Newark, N. J., Medical and Surgical Society; Tinselman Club of Buffalo, N. Y.

**Friday, May 22nd.**—Academy of Pathological Science, New York; New York Society of German Physicians; New York Clinical Society.

**Saturday, May 23rd.**—West End Medical Society, New York; New York Medical and Surgical Society; Harvard Medical Society, New York; Lenox Medical and Surgical Society, New York.

## Proceedings of Societies.

**THE ASSOCIATION OF AMERICAN PHYSICIANS.**  
*Twenty-third Annual Meeting, Held in Washington, May 12 and 13, 1908.*

The President, Dr. JAMES TYSON, of Philadelphia, in the Chair.

**The President's Address.**—Dr. TYSON referred to the organization and development of the association, and spoke of some of the eminent men who had been members and officers in past years. He referred to the numerous papers of great scientific importance that had been read at its meetings and that were collected into the twenty-two volumes of its *Proceedings*. During the year Dr. Charles Follen Folsom, of Boston, and Dr. James Carroll, of the United States Army, had been removed by death.

**Experimental Ligation of the Coronary Arteries of Dogs, and Its Bearing on the Treatment of Angina Pectoris.**—Dr. JOSEPH L. MILLER and Dr. S. A. MATTHEWS, of Chicago, said in this paper that it had been found that after ligation of the main trunk of one of the coronary arteries the heart stopped beating. According to some investigators, both ventricles stopped at once; according to others, the ventricle which was supplied by the ligated vessel ceased beating first. According to Spalteholz and Hirsch, the coronary arteries were not terminal arteries. The work undertaken by the writers of the paper had had for its object the determination of the relation of ligation of the coronary arteries to the symptom complex known as angina pectoris. It was noted that after the operation clinical features closely resembling those of angina pectoris developed. The animals used were divided into three groups. One group was untreated; one was treated with nitroglycerin after the operation; and the other group was treated with digitalis or strophanthus. Nitroglycerin apparently did the animals no good after the operation, but strophanthus, on the other hand, elevated the blood pressure and improved the systole. These results appeared to confirm the statement that the digitalis group was better for the treatment of angina pectoris than the nitrates.

Dr. WILLIAM H. WELCH, of Baltimore, asked if the investigation had added anything to our knowledge of the terminations of the coronary arteries. It was generally believed that the intramuscular branches of the coronary arteries were terminal, and that the epicardial branches had anastomoses. It had always been held that anæmic necrosis was constant after closure of the intramuscular vessels.

Dr. S. SOLIS COHEN, of Philadelphia, said that it was by no means sure that the post mortem lesions represented the conditions present in the early stages of angina pectoris. These lesions represented the results of permanent interference with the circulation. The paroxysm of angina pectoris was a temporary condition, not a permanent one. Those paroxysms which ended in death could not, of course, be relieved with nitroglycerin. On the other hand, the temporary attacks were relieved with nitroglycerin.

Dr. ROBERT W. HATCHER, of Chicago, said that it was his opinion that the blood pressure had much to do with the attacks of angina pectoris and the influence of the nitrates. If there was a high sys-

tolie blood pressure the nitrites relieved the attack; if, on the contrary, the systolic pressure was low, the nitrites failed to relieve.

Dr. ALEXANDER MCPHEDRAN, of Toronto, said that, in his experience, when the blood pressure was high, the nitrites did not relieve the attack. He referred to a case in which the systolic pressure was 217 millimetres, in which no results were obtained with nitroglycerin.

Dr. MILLER said that he had not studied the effects of the ligation of the intramuscular vessels. In his experiments the left ventricle had always been arrested first. He believed that the paroxysms of angina pectoris were not due to a temporary condition, but that we were dealing with the permanent occlusion of a vessel. The necessary feature of treatment in such cases was to endeavor to improve the condition of the heart muscle, not to relieve peripheral tension.

**Some Lesions of Experimental Nephritis.**—Dr. H. A. CHRISTIAN, of Boston, presented the results of a study of the pathological conditions found in experimentally produced nephritis in dogs. He had found, first, a glomerular lesion which presented the appearance of droplets, of varying degrees of coarseness, which stained blueblack with Mallory's phosphotungstic acid, hæmatoxylin method, in the walls of the glomerular vessels. These droplets were found in eleven out of thirteen animals in which nephritis had been produced by uranium nitrate. In twelve control animals in which the nephritis had been produced by other substances this lesion was found but twice, and then in relatively small amount. Second, he had found hyaline droplets in the renal epithelium lining the tubules in dogs poisoned by uranium nitrate, in cases of acute nephritis in man, and in the toxic nephritides of other animals. Third, in some of the animals poisoned by uranium nitrate he had found a change in the epithelium lining the collecting tubules, and to a less extent in that lining the convoluted tubules, which was characterized by an increase in the thickness of the hyaline layer at the base of the epithelial cells, and a loss of nuclei and of the granules in the cytoplasm of the cells.

**A Review of Theoretical Considerations and Experimental Work Relative to Opsonins, with Observations Made at the Saranac Laboratory.**—Dr. EDWIN R. BALDWIN, of Saranac Lake, N. Y., doubted the occurrence of specific opsonins in blood serum. He believed them to be the same as the body known as the amboceptor. At the Saranac Laboratory he and his coworkers had found that protective inoculations of weakly virulent opsonized bacilli in guinea pigs provoked more extensive and more severe local inflammation. After the use of tuberculin for diagnostic purposes, no constant influence on the opsonic index was noted.

**A Classification of Acidoses.**—Dr. JAMES EWING, of New York, said that acid intoxication occurred in diabetes, starvation, phosphorus poisoning, the toxæmia of pregnancy, cyclic vomiting of children, delayed chloroform poisoning, and other morbid conditions, in each of which the abstraction of fixed alkalis or the direct toxic action of the salts of the acid compounds was supposed to contribute to or to dominate the symptoms. He sug-

gested the following division of these conditions: 1. Experimental type, hydrochloric acid poisoning; clinical forms, diabetic acidosis and the acidosis of starvation; the acetone bodies were present and the urinary ammonia was proportional to them; there were no characteristic pathological lesions in this form. 2. Experimental type, extirpation of the liver or Eck fistula; clinical forms, phosphorus poisoning, toxæmia of pregnancy, cyclic vomiting, chloroform poisoning; lactic acid was formed in the urine and urinary ammonia was in excess of the acetone bodies; pathologically, excessive fatty degeneration was found. While the urinary ammonia was accepted as the measure of acidosis, there was reason to believe that its significance was not the same in the two types of acid intoxication. The marked difference in the observed pathological changes in the two types would seem to distinguish them still further.

Dr. LEWELLYN F. BARKER, of Baltimore, referred to cases of acidosis in which there was high urinary organic acidity.

Dr. J. P. CROZER GRIFFITH, of Philadelphia, referred to the cyclic vomiting which was said by some observers to be due to acetonaemia, but said that he could not agree to that theory.

Dr. DAVID L. EDSALL, of Philadelphia, agreed that there were two types of acidosis, but the whole subject was still very indefinite.

Dr. S. SOLIS COHEN, of Philadelphia, said that the acid excreted was certainly doing no harm, and asked if there was not also acid retention. He could conceive that acid intoxication might be due to the excessive neutralization of alkalis.

Dr. EWING said that it was doubtful if the acetone in the blood was sufficient to account for the symptoms of cyclic vomiting in children. He was aware of the uncertainty of the whole subject. The significance of the formation of ammonia was not definitely known, but it was thought to be a compensatory process. He, however, believed it to be more than that. The estimation of acidosis by the urinary ammonia was unsatisfactory.

**Experiments with an Ash Free Diet.**—Dr. E. P. JOSLIN and Dr. H. W. GOODALL, of Boston, had fed two healthy men on Taylor's ash free diet, composed of the whites of eighteen eggs, 200 grammes of crystallized sugar, and 120 grammes of olive oil freed from salts, until the daily excretion of chlorine was as low as 0.17 gramme. No symptoms of acid intoxication appeared, and at no time was acetone detected either on the breath or in the urine. The two subjects experienced marked loss of weight. In a first experiment the weight was regained within four days after a return to an ordinary diet. In a second experiment the weight was nearly all recovered in three days, when twelve grammes of salt was added to the salt free diet daily. The assimilation of food was excellent, although the subjects had no appetite and were mentally depressed. In one of the subjects 4,090 c.c. of urine was passed four days after the return to a normal diet in which there were twenty-five grammes of chlorine. The urinary ammonia was increased slightly toward the end of the experiment. In a case of diabetes with moderate nephritis absolute carbohydrate intolerance developed during an acute

illness. The chlorine in the urine gradually fell to less than 0.4 gramme in twenty-four hours, but the change in acidosis was insignificant. The experiments did not confirm the observation that an ash free diet produced acidosis. The withdrawal of salts, on the other hand, caused no change in metabolism, and produced no acidosis.

Dr. EDSALL said that Dr. Taylor's experiments had no bearing on diabetic acidosis or on the metabolic changes of carbohydrates and fats. The results did show that there were two forms of acidosis. As Taylor got an acidosis in himself on this diet, it indicated that there was more than one cause for the condition; at times acidosis might follow the administration of a salt free diet.

Dr. EWING said that he had drawn the same conclusion from Taylor's work that Dr. Joslin had. The central point in the discussion was, How much withdrawal of alkalies could be stood without the production of symptoms?

Dr. JOSLIN said that Dr. Taylor deserved great credit for inaugurating a new form of diet, which had led to interesting results.

#### On the Relation of the Parathyroid Glands to Calcium Metabolism and the Nature of Tetany.

—Dr. W. G. MACCALLUM and Dr. CARL VOEGTLIN, of Baltimore, pointed out that the convulsive and other symptoms of tetany which resulted from the extirpation of the parathyroid glands might be rapidly benefited by the administration of a soluble salt of calcium. Given by the mouth, it was not so rapidly curative as by intravenous administration. Metabolism studies on dogs with tetany had shown an increased calcium elimination, while the blood and the tissues were found to be deficient in calcium. It appeared probable that the parathyroid bodies had a control over the calcium metabolism, and that loss of calcium from the brain and the other tissues was the cause of tetany.

Dr. JOHN H. MUSSER, of Philadelphia, referred to a case of adenocarcinoma of the thyroid body and lymph nodes of the neck in which the parathyroid bodies were probably removed with the diseased tissues. Five days after the operation tetany developed. Large doses of calcium lactate, in combination with morphine, relieved the symptoms. Forty-eight hours after the calcium lactate was withdrawn the symptoms of tetany returned. Calcium lactate was again given, and the symptoms disappeared.

Dr. E. H. GOODMAN, of Philadelphia, had studied the metabolism in Dr. Musser's patient. The calcium balance was minus on one day of tetany and plus on another day. He thought there was no relation between calcium and tetany. The persistently high urinary nitrogen excretion in this case made one suspicious of an acidosis as responsible for the symptoms. It was possible that calcium under such circumstances acted as any base would act.

Dr. S. J. METZGER, of New York, referred to a case of tetany in the practice of Dr. Elsberg. Upon the administration of calcium lactate the symptoms subsided. When the calcium salt was omitted for forty-eight hours the symptoms returned, to disappear upon the readministration of calcium lactate. It appeared to him that calcium was capable of correcting the balance of inorganic salts; similar results would be produced by sodium, potassium, or

magnesium. In other words, it might act by preserving the equilibrium of inorganic metabolism.

Dr. EDSALL referred to a case of myasthenia gravis, in which a study of the metabolism showed an excess of calcium in the urine. Similar results had been seen in his laboratory in acromegaly and in cases of acidosis. He did not know whether there was an excess or a diminution of calcium in the blood. He had given calcium lactate to the patient with myasthenia gravis with benefit.

Dr. MACCALLUM had seen a case of tetany in a woman which was relieved by calcium lactate and recurred when the calcium salt was stopped. He had also an idea that there was a relation between acidosis and tetany, as the amount of ammonia in the blood was increased.

**An Unusual Paroxysmal Syndrome Probably Allied to Recurrent Vomiting, with a Study of the Nitrogen Metabolism.**—Dr. THEODORE JANEWAY, of New York, reported the case of a girl, aged sixteen years, who had had attacks characterized by epigastric pain, general abdominal pain, pain in the shoulder, hips, and other joints, loss of appetite and salivation, fever to 104°, a rapid pulse to 140, nausea, vomiting with retching, a heavy but not sweet breath, rigidity and tenderness of the abdomen, mostly in the right lower quadrant, polymorphonuclear leucocytosis, and loss of weight. These attacks had been experienced since birth at varying intervals. After the attack there was leucopenia, with renewal of weight and strength. The saliva was always acid; the vomitus contained abundant free hydrochloric acid; the stomach contents between the attacks showed excessive hydrochloric acid; the urine usually showed a trace of albumin and acetone. A study of the metabolism on a purin free diet showed little deviation from the normal, except for a marked decrease in the uric acid and a slight increase in the urinary ammonia during two of the attacks. The condition might be due to a recurring infection, such as a small pancreatic calculus, with inflammation, a recurring toxæmia, or a neurosis.

Dr. E. P. JOSLIN, of Boston; Dr. WALTER B. JAMES, of New York, and Dr. DAVID L. EDSALL, of Philadelphia, referred to similar cases. Dr. Edsall had eliminated fats from the diet in his case, and the patient had had no attacks for a year.

Dr. JANEWAY referred to the possibility of such a patient being operated on for appendicitis.

**Some Cases Presenting a Recurrent Syndrome Apparently Due to Exposure to Heat.**—Dr. EDSALL reported four cases which he had observed in which, after exposure to intense heat, the patients had exhibited a high degree of hypermyotonia, resembling tetany. There was no exaggeration of the reflexes, no central nervous system symptoms, and all indications pointed to a peripheral condition due to heat. There were cramps in the legs. Blood pressure observations, blood counts, and ordinary routine urinary examinations indicated that the condition was probably toxic. Since observing these cases he had discovered by correspondence that in the merchant marine, the United States Navy, and the Pennsylvania Railroad service the syndrome was well known and was considered to be due to heat. In the navy as many as 100 cases to 1,000 men have been observed annually.

*To be continued.*

## Pith of Current Literature.

### THE BOSTON MEDICAL AND SURGICAL JOURNAL.

May 7, 1908.

By FRANKLIN W. WHITE.

2. **Some Blood Pressure Observations in Eclampsia.**—Badger has studied this question and observes that the blood pressure in eclampsia is high, and of diagnostic and prognostic importance. In spite of improvements in subjective symptoms and increase in the quantity of urine, the blood pressure may remain high, in which case the prognosis is grave, and labor ought to be induced. The continuance of high blood pressure during the puerperium warrants a grave prognosis as to complete recovery.

6. **The Histology of Multiple Myeloma.**—Christian has observed eleven cases of multiple mye-

loma. The histological study of these cases shows a striking similarity of cell structure with differences of minor degree. The common characteristics of the cells are a finely granular, slightly basophilic cytoplasm, an eccentrically placed nucleus, a nucleolus, centrosomes, a nuclear membrane, and a tendency to mural arrangement of the chromatin. Certain nuclear changes, regarded as the results of degeneration, are commonly found. Mitotic figures occur in most of the cases studied by him, though absent in a few. Myelomata are to be classed with the tumors. They tend to remain localized in the bone marrow, but almost all show evidence of invasive growth into adjacent structures, and in a few metastasis has taken place. These tumors, then, are malignant in the usual sense of the word, but their malignant properties are apt to appear relatively late in many cases. With these characteristics there is a greater resemblance of the tumor cells to bone marrow plasma cells than to myelocytes. In most of the cases reported by other observers the cells show these characteristics and these tumors from a group within which the cells of individual cases show no greater variation than occurs in other tumor groups.

9. **The Diagnosis of Circulatory Conditions by Temperature Measurements.**—Eastman has found that the variation in temperature between rectum and hand in healthy persons averages  $0.6^{\circ}$  to  $1.3^{\circ}$  C., and is greater in cases of cardiac disease, except in aortic insufficiency. There is a characteristic difference in the peripheral circulation in aortic insufficiency as contrasted with other heart lesions. Muscular exertion, even to fatigue, in a person with a normal heart, causes a rise in temperature in the extremities. Fatigue in a case of cardiac decompensation causes a fall in the peripheral temperature. Therefore this method of temperature measurement is a simple and useful addition to the other methods in use for the examination of cardiac cases, and for the distinction of cardiac sufficiency or insufficiency. It is a means of determining the effect of exercise, either active or passive, upon cardiac cases, and furnishes us with a method of distinguishing the œdema arising from passive congestion from that due to nephritis.

11. **The Clinical Value of the Estimation of Ammonia in Diabetes.**—Goodall and Joslin find that quantities of ammonia reaching 5 grammes in twenty-four hours indicate an extremely severe form of diabetes, which usually proves fatal within a year. Patients under forty years of age tolerate an acidosis estimated in terms of 4 to 5 grammes ammonia far better than those above fifty years tolerate an acidosis of 2.5 to 4 grammes ammonia. An acidosis in an individual above fifty years of age is of a very serious prognostic import. A knowledge of the ammonia excretion usually helps in the treatment of a case of diabetes, and generally, but not always, gives warning of impending danger. The value of a knowledge of the ammonia excretion in the prognosis of a diabetic patient is enhanced by a knowledge of the quantity of albumin and carbohydrate in the diet. A lowering of the carbohydrate intake in a severe case of diabetes from a total of 80 grammes to 55 grammes in twenty-four hours produces little effect upon the acidosis.

21. **The Origin of Urinary Casts.**—Smith has

made some experiments on rabbits in producing nephritis, using uranium nitrate, potassium bichromate, trypan red, arsenic, and cantharides. He found that it is possible by the injections of irritants to produce in rabbits an albuminuria and cylindruria dependent upon lesions of the kidney simulating nephritis in man. Granular casts are the first to appear in the urine when the kidney is attacked by an irritant. Casts are more common in the urine when the kidney lesion is primarily a necrosis of the tubular epithelium, and arise from the degeneration and necrosis of the cells of the tubular epithelium of the kidney. Entire necrotic cells may desquamate and at first remain distinct from one another, then become massed together, and finally formed into a definite plug, taking the shape of the tubule in which it is formed. The same process takes place with cell fragments and granular material derived from disintegrated cells. The casts are all granular at first and later become hyaline as they pass down the tubule in the urinary stream.

**22. Age in Its Relation to Arteriosclerosis and Death from Arteriosclerosis.**—Smith found that in his series of 2,000 autopsies, 442 cases, or 22.1 per cent., showed more or less arteriosclerosis. Arteriosclerosis was three times as common in the male as in the female. It occurred no earlier in the colored race in this series. The average age of the cardiorenal group was nearly fifty-five. The average age of the cerebral group was nearly sixty. Fifty per cent. of the cases of cerebral hemorrhage occurred in the fifth and sixth decades, and was three times as common in the male as in the female. All the cases of aneurysm were in males. The average age of death was nearly forty-five. Death from gangrene and diabetes was incident to the last decades—the sixth and seventh; the average age nearly sixty-five.

By ROBERTSON LEITCH.
7. Hatchup and Chert Palate.  
By ARTHUR WOOD HENRIET.

**2. Distinction of *Bacillus Coli Communis* from Allied Species in Water.**—Rivas thinks that the saccharolytic group represents not only one but different kinds of microorganisms commonly found in nature, especially in water, characterized by its predominating action in splitting dextrose. The constant occurrence of this group in water may prove to be a factor in itself which may shed a new light on our vital problems of the bacteriology of water. The *Bacillus communis* must not be confounded with the colon group, which he calls "saccharolytic group," believing that this group should have no relation to the colon bacillus. Since the saccharolytic group is shown to be more closely related to what at present

is regarded as the colon group, the substitution of "saccharolytic group" for "colon group" is more comprehensible, and he thinks will aid considerably, not only in relieving the confusion which the colon group presents, but especially in establishing the colon bacillus as a distinct type of microorganism and not an indefinite chain of them, as it is considered at present. *Bacillus coli communis*, in addition to the recognized characteristics, will fail to exhaust the sugar in 1 per cent. dextrose bouillon at 37° C. in forty-eight hours, while contrary to this, the saccharolytic group may in many ways present characteristics of the colon bacillus, but will always exhaust the sugar in forty-eight hours at 37° C. in 1 per cent. dextrose bouillon. *Bacillus coli communis* should be discarded as an agent for exhausting the sugar in the meat juice and one of the saccharolytic group should be used instead.

**3. Psychotherapy.**—Hinkle understands under psychotherapy all forms of mental treatment, whether accompanied by hypnosis or without. The hypnotic state is not primarily the result desired, but the receptive condition induced by that state, in order that the curative suggestion given may be accepted without interference from the objective self. Hypnosis of itself without suggestion never accomplished anything; the forceful directions given the patient during the responsive state of hypnosis achieve the results. The author has had six years of experience with suggestive therapy, the last two years exclusively, and she finds that the most intelligent Americans yield more readily to mental treatment than the foreign born clinical patients. There are two distinct types of patients—the one who is afraid he will go to sleep, and the other who is afraid he will not. Both of these have to be met and dealt with accordingly. The former, after a few simple explanations, usually lose this feeling. The latter class are perhaps a little more difficult, because as a rule they have fixed ideas as to the only way in which they can be helped, and if they are not conscious of being asleep and amnesic they will declare that they are not influenced at all, and by their own strong autosuggestion in many cases will counteract the physician's influence. In a few of these cases, when reason could not be used, she has employed hypnotic drugs for their quieting influence and to heighten the verbal suggestion. In all she has used these drugs about six times, giving either bromide or paraldehyde. The results have been favorable in all the cases except one insomniac patient, and in that case she could neither influence the patient with drugs or without, and apparently made no impression of any kind. It is not wise to use drug therapy at the same time as suggestive therapy, for the divided attention of the patient seems to weaken the suggestive effect, and for that reason he never combines the two unless it is especially indicated, or is merely the prescribing of a simple tonic.

**6. Practical Cystoscopy: Its Scope and Limitations.**—Lewis remarks that the purposes of urethral catheterization are twofold, for diagnosis and for treatment. The diagnosis of (A) is based on the origin of pus, blood, tuberculous products, or bacteria; the various pyogenic infections, abnormally desquamated epithelium, etc., as to whether they come from (1) the bladder, (2) the right ureter, (3) the

left ureter, (4) the right kidney, (5) the left kidney, (6) the right or (7) the left perirenal space, communicating with the corresponding kidney or ureter. (B) To recognize and locate obstructive conditions in the right or left ureter from (1) stricture, (2) stone, (3) adjacent tumor, (4) bend or kink in the ureter from movable or dislocated kidney, (5) valvular junction of the ureter with its pelvis. (C) To determine (1) the number of kidneys present; (2) if only one, which is absent. (D) To determine the number of ureters present. (E) To determine the functional activity of each kidney separately and relatively, with respect to its excretion of urea, albumin, quantity of urine, the specific gravity, etc. (F) To determine the size and capacity of each kidney pelvis, with respect to (1) hydronephrosis, (2) pyonephrosis, (3) total obliteration of secreting tissue. (G) If there is kidney disease present, to determine (1) if only one kidney is affected or both; (2) if only one, which is the affected one; (3) if both, which is the one more affected; (4) if removal of the worse one be advisable, is the other one able to carry on kidney function sufficiently; (5) if removal of one be advisable and the other is capable of supporting life, will the operation remove the infection from the body, removing the possibility of dissemination or recontamination? For Treatment.—(A) To enlarge narrowings or strictures at (1) the ureter openings, or (2) in the channels at any point; (3) by facilitating drainage through the increased ureter calibre thus obtained, to assist in the improvement of pyelitis or pyonephrosis, unilateral or bilateral. (B) To irrigate and medicate (1) the ureters, (2) the kidney pelvis, of one or both sides. (C) To assist, by anesthetizing, lubricating, or enlarging a ureteral orifice, the passage through it of a calculus or plug of pus, blood, etc. (D) To use the ureter, after it is catheterized, as a guide in certain abdominal and pelvic operations. (E) By prolonged catheterization and drainage of a ureter, to facilitate the cure of ureteral fistula.

3. Report of Nine Cases of Fracture of the Carpal Scaphoid, By LEONARD W. ELY.
4. The Pulse of the Nervous System, By J. HENRY DOWD.
5. Some Considerations in the Management of Burns and Scalds in Infants and Children, By MEDWIN LEALE.
6. A Report of Fifty Cases Tested by the Calmette Ophthalmoreaction Test for Tuberculosis, By CHARLES GRAEF.
7. Success and Failure in Nauheim Cures, By PAUL C. FRANZE.

1. **Darwinism and Diabetes.**—Eccles remarks that nothing in Nature is more closely associated with every form of evolution than is disease. The healing forces are as truly physiological as are those of assimilation and growth. The processes of disease are aimed not at the destruction of life, but at the saving of it. If it were not for disease in the popular sense the human race would soon be extinct. These sentences the author has taken from a speech of Sir Frederick Treves. For centuries there has been presented the strange spectacle of men of science struggling to the utmost to thwart, to curb, to

annihilate, a process of cure. Unfortunately for the ailing, this strange spectacle is far from having ceased, although in one or two instances it has been checked. The author takes up one general reaction of organisms toward adverse condition, hyperglycæmia and glycosuria. He states that the present attitude of almost the entire profession toward it is pre-Darwinian. Citing some clinical cases of the influence of sugar, he says that these evidences have been confirmed by animal experiments. Exceedingly large quantities, as compared with the amount in normal blood, have been subcutaneously injected into dogs, without the slightest signs of toxicity. The experiments demonstrated that the animal body has great power in utilizing dextrose when administered in this way. The fear of sugar, as sugar, is probably a vestige of the time when no one was allowed to sell it but the dealer in poisons, and he dared not dispose of it without a physician's prescription. The ghosts of such antiquated notions still continue to interfere with logical thinking even among many who think themselves entirely emancipated from them. If more evidence is still demanded in proof of the harmlessness of sugar the geographical and social distribution of diabetes ought to be sufficient. Find a place where sugarcane is grown, and sugar consumed in abundance, and one is found in which diabetes is exceedingly rare or else is unknown. Find a region where carbohydrate food constitutes the bulk of that consumed and that place will be found to contain little diabetes. Discover a race that subsists exclusively on carbohydrate food and we discover one that knows no diabetes. Find a religion whose votaries must subsist exclusively on a vegetable diet and one will be found that knows little or nothing about diabetes. Now, on the other hand, the discovery of a class, people, or faith, where meats are largely consumed is quite likely to be one in which the death rate from diabetes is at its maximum. Such at least has, so far, been the results reported by those who have made a study of its geography. If we turn to Europe and America what do we discover? The very men and women whose daily food comes most nearly up to the standard of diet prescribed for diabetics are the very men and women in whom the cases of diabetes are most numerous and most fatal. They are the people whose daily ration is filled with fish, flesh, and fowl, and in which but little room is left for bread or potatoes. The plain people who subsist on the more economical diet, a diet chiefly carbohydrate, know but little of diabetes. It is those who regale on table d'hôte dinners who are the sufferers. They fill up on chicken and turkey, quail and partridge, venison and mutton, beef and oysters, fish and lobster, with only a minimum of carbohydrates. With an increase in the wealth of a nation comes an increase in the number of cases of diabetes, and *pari passu* with this, an increase in the consumption of proteid with a corresponding decrease in the consumption of carbohydrates.

3. **Fracture of the Carpal Scaphoid.**—Ely draws the following conclusion from nine cases: Fracture of the scaphoid is comparatively frequent, and is often mistaken for sprain of the wrist. It often escapes detection and recovers without any treatment. It is usually caused by a fall on the extended hand. It may be caused by punching with

the clenched fist, or rarely by superflexion of the hand. The one important symptom is tenderness over the scaphoid on the dorsum of the wrist in the "tabatière," or slightly internal to this spot. All the other classic symptoms of a fracture may be absent, except pain on motion. If the fracture is accompanied by a dislocation of the semilunar, extension of the fingers, especially of the middle finger, will be limited and painful, and the disability will be much greater. The prognosis of simple uncomplicated fracture of the scaphoid is good; that of fracture with dislocation is less favorable. A good treatment of simple fracture is immediate immobilization. If the semilunar is dislocated, a piece of the scaphoid often goes with it. If a dislocation is present, the dislocated bone must be replaced. If this is not possible, then it should be removed. Roughly speaking, sensitiveness over the scaphoid, with a history of a fall on the extended hand, without much disability or swelling, means simple fracture. If great swelling and disability are present, and the middle finger is held in rigid flexion, a dislocation accompanies the fracture.

**6. The Calmette Ophthalmoreaction Test for Tuberculosis.**—Graef has tested the tuberculin ophthalmoreaction of Calmette in fifty cases. He thinks that the test seems to be a fairly reliable one, well worthy of wide and repeated trial at least. In some advanced cases no reaction will occur, a matter of little moment if the test proves reliable in early cases, whatever the reason for this peculiarity may be. Some allowance should be made for possible faults in the tuberculin as furnished at present. From the observations made on these cases he regards the ophthalmoreaction as good evidence of the presence of tuberculosis. In one of the cases a diagnosis made in this way was afterward confirmed by finding the bacilli in the sputum.

By MAURICE GREENWOOD, JR.

**1. Xanthelasma Palpebrarum.**—Hutchinson states that the usual site of *xanthelasma palpebrarum*—the wash leather patches on the eyelids—is in crescentic grouping above and below the inner canthus of the eyelids. They occur in adults or middle aged persons who have usually accounted themselves "bilious," and are more common in dark complexioned persons than in the fair. After middle age they cease to develop and may disappear,

which suggests that the sexual system may have something to say to the recurring attacks of liver disturbance. Those who develop these wash leather patches have almost always been liable to periodic disturbances of pigmentation in the eyelids. Once a month or oftener the thin skin of the eyelids has been prone to become dark by temporary increase of pigment. In women they often reveal the menstrual periods. It is from these attacks of temporary, but often recurring, attacks of pigmentation that the *xanthelasma* patches take their origin. They result from the deposit of a fatty acid derived from the bile and are to be regarded as a late result. They are not the only consequence of the recurring nutritional disturbances: The gland structures may suffer also and now and then the papillæ. The writer classifies the several forms which occur as follows: 1. *Xanthelasma planum* or *flavum*, the wash leather type described originally by Rayer. 2. *Xanthelasma sebaceum*, where comedones are present. 3. *Xanthelasma cysticum*, when cysts are present. 4. *Xanthelasma pigmentosum*, when dark pigmentation is the only condition.

**2. Puerperal Fever.**—Gordon holds that puerperal fever is wound fever. The wound is present after every labor at the placental site. When it becomes infected we may have: 1. Rapidly generalized septicæmia, from passage of the organisms directly into the veins of the part. This form is usually fatal in from one to three days, and the circulating blood generally contains streptococci. 2. Direct extension through the Fallopian tubes to the peritoneal cavity, and resulting general suppurative peritonitis. 3. Extension as far as the Fallopian tubes only, with formation of adhesions, shutting off the general peritoneal cavity, resulting in the occurrence of pyosalpinx, pelvic peritonitis, or tubo-ovarian abscess. 4. Lymphatic extension, causing parametritis, which may go on to suppuration. The infecting agent in all forms is usually a streptococcus, but the colon bacillus is often found later. Occasionally the whole system becomes invaded by this bacillus as a terminal infection. The following points must be observed in treatment: 1. The avoidance of anything that may interfere with the closing of the placental site, such as the retention of placental tissue, etc. 2. Care should be taken that no other wound be made, *e. g.*, with the forceps. 3. Infection of the wound should be avoided by abstention from too frequent vaginal examinations, and by the wearing of rubber gloves. 4. Douching the vagina is seldom necessary and always risky. A rubber syringe should never be used. 5. The vulva should be kept covered with an antiseptic pad. There are two main modes of treatment: The passive and the active. The former is based on the belief that between the organisms and the host lies a barrier of leucocytes which should be left intact and not destroyed by any local disinfection. The writer, however, believes in active treatment—curtailing and swabbing with strongly bactericidal chemicals. In the treatment of the septicæmic conditions themselves there is nothing equal to large quantities of sterilized saline solution given per rectum or subcutaneously. With these may be combined camolene and alcohol, both in fairly large doses. Antipyretic drugs are usually harmful; cold water is the best treatment for pyrexia *per se*. Anti-

streptococcic serum is useful in a limited number of cases only, but is never harmful. The serum should be polyvalent, *i. e.*, prepared from many strains of streptococci, some of which should have been obtained from cases of puerperal fever. At least 50 c.c. should be given subcutaneously, and twice as much is preferable. The dose should not be repeated, as joint pains and pyrexia are apt to result. The type of case in which these bactericidal serums are of benefit is that in which the streptococci are present in the circulating blood. They probably do not affect the local lesion at all, and their value in checking absorption of toxins from the lesion is problematical. They are not supposed to have any antitoxic value.

**6. Solitary Kidney.**—Ward reports a case of that rare condition known as "solitary kidney." The term has been widely and loosely used, and includes the three following classes: 1. Congenital absence of development of one kidney, its vessels, and the corresponding ureter. The remaining kidney is hypertrophied and may occupy its normal position in the loin, the ureter opening into the bladder in its normal position. 2. Fusion of the two kidneys into one mass, the simplest and best known form of which is the "horse shoe kidney," in which two of the poles are united by a bridge of kidney substance across the middle line. There are never less than two ureters, and sometimes three or four. 3. Cases in which one kidney is either rudimentary, degenerated, or so diseased as to be incapable itself of carrying on the excretory needs of the body. This is the class most frequently met with by surgeons. The methods of diagnosis at our command are cystoscopy, segregation of the urine by separation of the bladder into two halves by a special instrument, and inspection of the two kidneys, this last requiring a second operation.

## LANCET

April 25, 1908.

1. The Gresham Professors of Physic (Gresham Lecture),  
By F. M. LANDWITZ.
2. The Anatomy of the Long Bones Relative to Certain  
Fractures (Hunterian Lectures, II),  
By R. THOMPSON.
3. On So Called Rheumatic Iritis.  
By C. HIGGINS.
4. The Influenza Bacillus as a Cause of Fatal Endocarditis after Eight Years (?) (An Influenza Carrier?),  
By F. J. SMITH.
5. The Accuracy of Opsonic Estimations,  
By L. NOON and A. FLEMING.
6. Chronic Polycythæmia,  
By E. CANTLEY.

**2. Fractures of the Long Bones.**—Thompson, in the second of his Hunterian lectures, discusses fractures of the upper extremity and shoulder girdle. In Colles's fracture the main pressure is transmitted through the posterior part of the radius. When a breaking strain is applied the anterior or concave part of the radius, which really corresponds to the convex side of the arm, is put upon the stretch and smashes first, and then the line of fracture is directed along the line of pressure lamellæ, *i. e.*, along the grain of the bone. Hence the obliquity of the line of fracture from below, obliquely upwards and backwards. The transverse line of fracture may be explained by the fact that in coronal sections of the bone the lamellæ are not nearly so pronounced as in sagittal sections, and therefore will not affect the line of fracture to any marked extent. In fracture of the clavicle, no pressure, or very lit-

tle, is transmitted through the acromioclavicular joint, even when blows are struck upon the outer edge of the acromion process. This absence of direct pressure through the acromioclavicular joint is explained by the presence of the trapezoid ligament and its attachment to the coracoid process of the scapula and the clavicle. The pressure which passes through the coracoid process and the trapezoid materially affects the internal structure of the clavicle. The obliquity of the adjacent surfaces of the acromio clavicular joint and the presence of the triangular fibro cartilage still further diminish shock. By direct impinging of the coracoid process against the clavicle fractures of the clavicle between the conoid and trapezoid ligaments are produced, and with such fractures not only is displacement possible, but impaction may also take place. By bending of the clavicle over the coracoid process fracture of the shaft of that bone may be produced.

**3. Rheumatic Iritis.**—Higgins states that iritis dependent on rheumatism no doubt frequently occurs, but a very large number of cases so called are due to the poison of gonorrhœa, and the worst cases almost always. The patients are almost always men, over thirty years of age, and give a history of gonorrhœa, often of repeated attacks. In most cases an attack has not immediately preceded the iritis. More likely the last attack of gonorrhœa was some years previously. In most cases there has been no gonorrhœal rheumatism. The iritis is severe and all the usual symptoms are well marked. It is painful, often severely so; there is swelling of the iris, generally much photophobia; a strong tendency for adhesions to form, though there is no very great amount of exudation, with much ciliary and conjunctival congestion. There are also a decided inclination to contraction of the pupil, which strongly resists the action of mydriatics, of which there is often a marked intolerance; a tendency to increased tension; a general intractability, rendering treatment most difficult and its results most disappointing; and an unlimited capacity for recurrences continuing through any number of years. The liability continues through the whole of sexual life. It is probable that in many men who have had gonorrhœa severely and frequently there is left for many years in some part of the urinogenital apparatus a very much attenuated virus which gives no trouble locally, but from time to time becomes more active, and though still setting up no local irritation is capable after absorption of causing inflammation in synovial membranes or in the iris. It looks almost as if the iris becomes, on occasions, an excretory organ and tries to eliminate the poison, receiving considerable damage itself in the attempt. There must also be a large personal element or idiosyncrasy. The results of gonorrhœal iritis include all those consequent on iritis in its worst forms: Synechia, more or less extensive, occluded and excluded pupil, complete adhesion of the posterior surface of the iris to the lens capsule, *bombé* iris with its attendant evils, capsular cataract, glaucoma, with changes in structure of the iris, and loss of vision, varying from slight impairment to total blindness. Treatment is most unsatisfactory. Mydriatics irritate, and rise of tension is very frequent, so that they must be used with caution. Heat is very useful, especially where pain is a marked symp-

tom or where the tension is markedly increased. Blisters are not of much service, but leeches are often very beneficial, acting almost like magic in relieving pain. The writer sounds a note of warning against the use of cocaine and adrenalin. They do reduce vascularity and relieve pain, but their after effects are positively harmful, for they cause paralysis of the blood vessels and thus add fuel to the fire which they are intended to extinguish. None of them should be used, except for local anæsthesia in prevention of bleeding during an operation, or for the examination of painful or sensitive parts. Constitutional treatment should consist of free purgation and washing out the system by copious draughts of hot water; mercury, iodides, salicylates, and quinine. Salicylates are rarely useful, but aspirin relieves pain.

**6. Chronic Polycythæmia.**—Cantley reports a case of chronic polycythæmia occurring in a man, aged forty-seven years. Although any condition of cyanosis induces polycythæmia, it does not follow that the increase in the number of the red cells is due to the cyanosis. More probably there is an actual increase in the production of red cells, and the cyanosis is consequent on the increasing viscosity of the blood and difficulty in its efficient aeration. The considerable increase in the number of leucocytes, especially the polymorphonuclear forms, suggests that we have to deal with an inflammatory affection of the blood forming organs, possibly the result of some toxin. Venesection in the case here reported relieved the patient considerably. The omission of milk from the diet, and large doses of citrate of soda did not appear to produce any beneficial effect.

#### LA PRESSE MEDICALE

April 4, 1908.

1. The Treatment of Measles, By J. HALLE.
2. Should We Use Ethyl Chloride Mixed with Oxygen for Anæsthesia of Short Duration? By LUCIEN CAMUS.
3. Apropos of the Specificity of the Cutaneous Reactions, By R. ROMME.

**1. The Treatment of Measles.**—Halle remarks that there is no specific treatment of measles, and, as we are unacquainted with the germ responsible for the disease, and the disease seems to affect the human race alone, that it is not likely that we shall soon find a seropathic treatment with which to combat it. Although measles is known to be rarely mortal, yet under certain circumstances its fatality may become very great, and Halle considers that careful attention should be paid to children suffering from it, either in its simple or complicated form. In simple measles the child should remain in a well ventilated room kept at an even temperature, and proper hygienic precautions should be observed. Attention should be paid to the skin, the eyes, the nose, the mouth, the genitals, the digestive and the respiratory apparatus. Special attention should be paid to the dietary, into which the author enters very fully. In complicated measles the treatment given simple measles is indicated, together with the addition of therapeutic measures directed actively against the complications. The forms mentioned are the dyspnoea with absence of any physical signs of lung trouble, the hæmorrhagic, the hyperpyrexia, the atonic, and the adynamic. The complicating diseases mentioned are bronchopneumonia, laryngitis, diphtheria, otitis, and stomatitis.

**2. Ethyl Chloride for Anæsthesia.**—Camus considers that it is simpler and easier to give pure ethyl chloride gradually than when it is mixed with either oxygen or air, and that it produces anæsthesia more regularly. He asserts that the ethyl chloride should be given in known, small doses, so that it may be absorbed slowly, and the nervous system become gradually affected.

April 8, 1908.

1. The Reeducation of the False Gastropathies, By J. DEJERINE and E. GAUCKLER.
2. The Physicochemical Properties of Radium, By L. MATOUT.

**1. Reeducation of the False Gastropathies.**—Dejerine and Gauckler allege that in very many of the cases of gastric trouble that are met with the trouble is purely psychic and there is no true gastropathy. To correct these cases the authors present a set of rules covering the feeding of the patients for several weeks.

#### LA SEMAINE MEDICALE.

April 8, 1908.

Cyclothymia, By M. G. DENY.

**Cyclothymia.**—Deny states that this term was first introduced by Kahlbaum in 1882 to indicate circular insanity or neurasthenia, a condition which has attracted the attention of some writers. Deny finds that so many more women than men are affected that the female sex might be considered a predisposing cause of the disease. It may last all one's life without resulting in insanity. Its exacerbations coincide in general with the epochs of puberty and the menopause, and may be provoked by excesses, the emotions, severe hæmorrhages, and repeated pregnancies.

4. The Forms of the Tubercle Bacillus Not Demonstrable According to Ziehl's Method, By HANS MÜCH.
5. The Importance of Serum Diagnosis in the Pathology and Treatment of Syphilis, By A. BLASCHKO.
6. Concerning the Influence of the Reaction Upon the Accomplishment of Wassermann's Complement Union in Syphilis, By K. ALTMANN.
7. Symptomatology and Treatment of Cerebellar Tumors (continued), By L. STREIBLING.
8. Contributions to the Surgery of the Brain and Spinal Cord (continued), By HERMANN K. SCHNEIDER.

**1. Simulation of Idiocy.**—Knapp reports an interesting case in which a man maintained a simulation of idiocy for years for the purpose of mulcting the insurance companies in which he had taken out policies insuring his health. By this means he had greatly increased his income during the time his simulation remained undetected.

**2. Syringomyelia.**—Milchner describes a case of this disease met with in a man thirty-two years of age. It seemed to date back to a fall when the patient was ten years old, in which he struck on the back of his head, but suffered no immediate ill effects.

**3. Antiferment Action of the Human Blood.**—Marius says that for the determination of the power of the human blood to restrain the digestion of albumin by the Müller-Eichmann method a one per

cent. solution of trypsin is a positive test substance. The antitryptic strength of the blood serum corresponds to the normal when it prevents the formation of dimples on the Loeffler plate of a threefold volume of a one per cent. solution of trypsin. It is therefore diminished when it renders inactive less than a threefold volume of the trypsin solution, and increased in strength when it renders inactive a greater quantity. The antitryptic power of the blood serum varies from the normal in various pathological conditions. Further researches are necessary to determine whether any valuable clinical, diagnostic, or prognostic conclusions may be derived from the weakened or strengthened power of the blood serum to inhibit trypsin digestion.

7. **Cerebellar Tumors.**—Siemerling adds four more carefully observed cases, and then reviews the symptomatology presented in this condition.

8. **Surgery of the Brain and Spinal Cord.**—Küttner adds the following cases: One of palliative trepanation for a brain tumor, which was not localized, with almost complete restoration; one of cyst of the surface of the brain after fracture with depression productive of general traumatic epilepsy, which was operated on with a good result; one of exploratory laminectomy for a suspected gliomatosis of the spinal cord; one of tumor (psammoma) of the spinal cord successfully removed; one of fibroma of the caudia equina successfully removed. Throughout this long and valuable paper comments are made with regard to the individual cases, but very little is added in the way of general comment.

#### GAZZETTA DEGLI OSPEDALI E DELLE CLINICHE

March 22, 1908.

1. Yefimov's Test for the Diagnosis of Intestinal Worms, By M. V. CARLETTI and L. DOZZI.
2. Eosinophilia and the Antibodies in the Serum, By BAZZICALUPO.
3. On Hernial Tumors of the Omentum, By E. ARCOLEO.
4. Hyperæmia in Acute Superficial Inguinal Adenitis, By UGO GROINI.
5. A Case of Dorsal Dislocation of the Middle Carpal Bone, By V. SCOCIA.

1. **Yefimov's Test in the Urine for Worms.**—Carletti and Dozzi say that Yefimov's chemical and microscopical tests for the presence of worms is of no value. The chemical test which was suggested by the Russian author mentioned was as follows: From 5 to 10 cc. of recently voided urine were treated with five or ten drops of a solution of mercuric nitrate. A precipitate formed. If the latter was white, milky, the patient did not have any worms. If, however, the precipitate was greyish or more or less dirty, almost black, then the patient had intestinal worms. In order to avoid possible causes of error, the author advises that the patient should not take any medicine for several days before the test, because alkalis, sulphates, and compounds of lead, iron, etc., produce a greyish color in the precipitate. Albumin, glucose, indican, etc., do not modify the reaction. Pus, on the other hand, will cause it to color the precipitate a dark tint. The second reaction recommended by Yefimov is more important than the first, and not only indicates the presence of worms, but even shows what variety of worms is present. It consists in the microscopical examination of the crystals, which are obtained by evaporating a drop of the urine on a slide. Gran-

ular crystals indicate the presence of cestodes, while crystals in the shape of crosses show the presence of nematodes, or round worms. The simplicity of this test led the authors to experiment with it. They examined in a number of patients, some of whom were tuberculous, while others suffered from a variety of diseases, both the feces and the urine. The feces were examined in order to find out whether the eggs of parasites were present; the urine whether Yefimov's test could be obtained. The conclusions which the authors make as the result of the examination of eighty patients are: (1) The chemical reaction with the acid nitrate of mercury does not usually present the marked characteristics described by Yefimov. The color of the precipitate varies greatly without reference to the presence of worms. In two cases, in which the feces did not show the presence of intestinal worms, there was a distinctly dark precipitate. On the other hand, the precipitate was white in three cases in which the feces showed the presence of worms. (2) The presence of crystals in the urine of these patients did not correspond to the presence of worms. The shape of the crystals varied greatly in the same case at different times. In ten patients, who showed no eggs of parasites in the feces, only three showed crystals in the urine.

#### MÜNCHENER MEDIZINISCHE WOCHENSCHRIFT.

3. Sudden Death in Patients with Heart Disease, By KISCH.
4. Studies Concerning Tobacco Smoke, By LEHMANN.
5. Concerning a Simple Method of Demonstration of the Function of the Pancreas in Healthy and Diseased Persons, By SCHLECHT.
6. Demonstration of Pus by Millon's Reagent, By DREYER.
7. The Antiferments in Human Blood Serum, By JOCHMANN and KANTOROWICZ.
8. Concerning Skin Reactions after Inoculations with Dead Typhoid, Paratyphus Bacillus, and Coli Cultures, By LINK.
9. The X Ray Demonstration of Ossification of the Cartilages of the Ribs, By CRÖDEL.
10. Perhydrasemilkagar, a New Nutrient Material for Bacteria, By FRÄNKEL and MUCH.
11. A Simple Nutrient Material for Gonococci, By PIORKOWSKI.
12. Concerning the Transmutation of Lymphosarcomatosis and Tuberculosis, together with a Contribution to Experimental Cirrhosis of the Liver, By BRANDTS.
13. Persistent Anæsthesia in the Tuberculous Larynx, By HOFFMANN.
14. Fibrolysin in Groupous Pneumonia with Delayed Resolution, By KRISINGER.
15. Diagram of the Body, By HILDEBRANDT.
16. Concerning Thymus Persists and Apoptectiform Thyms Death, with Remarks Concerning the Relations of the Persistent Thyms to Exophthalmic Goitre (Concluded), By HART.
17. Obituary of Carl Binz, By SCHMIZ.
18. Japanese Women as Prostitutes and Prostitution in Japan.

2. **The Alternating Pulse and Its Relations to the Bigeminal Pulse.**—Von Tabora means by alternating pulse that form in which a stronger contraction of the heart alternates with a weaker one so that the interval between the latter and the former is as great or greater than that between the weaker and the subsequent stronger contraction. In the bigeminal form the stronger contraction alternates with the weaker but with an interval that is

always less than that between the weaker and the subsequent stronger contraction. Thus in the alternating pulse the weaker contraction of the heart takes place either at the right time or after the right time, in the bigeminal always before. The alternating pulse seems to be comparatively rare and the author reports a case.

**3. Sudden Death in Heart Disease.**—Kisch finds from a study of 156 cases of sudden death in patients with heart disease that prior to the age of thirty there is very little tendency to sudden death from cardiac lesions. Indeed where there is good compensation sudden death is almost as rare as in people without heart trouble. From thirty to fifty the number of sudden deaths increased progressively, and after the age of fifty valvular lesions form a factor which under certain pathological conditions may cause sudden death. As regards the conditions of the heart and vessels in these 156 cases thirty-five were cases of cor adiposum, thirty-two of myodegeneratio cordis, fifty-nine of endarteritis chronica, thirty-six of endarteritis aortae, seven of sclerosis of the coronary arteries, thirteen of mitral insufficiency, nineteen of mitral and aortic insufficiency, thirteen of aortic aneurysm, three of rupture of the heart, thirty-six of chronic nephritis, twenty-one of chronic emphysema of the lungs, and seven of cerebral hæmorrhage. It happened most often in persons with very fatty hearts and in persons with general arteriosclerosis. The immediately actuating cause is sometimes difficult to determine. Mental excitement is sometimes sufficient, sometimes it is caused by an increase of the blood pressure. Hereditary and meteorological influences also seem to take a part.

**4. Tobacco Smoke.**—Lehmann states that nicotine is an uneven mixture of a number of substances and a very strong poison. He does not think nicotine responsible for all the toxic symptoms produced by smoking and questions why, if nicotine is responsible, children exhibit symptoms of apparent nicotine poisoning after smoking parts of plants that are free from nicotine, why cigars that contain an equal amount of nicotine differ greatly in their effects, why cigars that are rich in nicotine are frequently milder than others that are markedly poor in nicotine, and why cigar tobacco seems to be so much stronger when smoked in a pipe.

**11. A Simple Nutrient Material for Gonococci.**—Piorkowski prepares his nutrient material in the following manner: A litre of fresh milk is mixed with 5 ccm. of dilute hydrochloric acid (1 in 4) and kept at a temperature of 37° C. until the casein has become separated. It is then filtered and the filtrate neutralized with a ten per cent. solution of soda. It is then cooked for two hours in a vapor bath, neutralized again, and then filtered once more. It is then placed in bulbs or test tubes and sterilized for an hour at a temperature of 100° C.

### New Inventions.

#### A LARYNX KNIFE AND SILVER NITRATE CARRIER.

By MURDO J. BATES, M. D.

New York.

While working at Hajek's Clinic in Vienna about six years ago I frequently met with intralaryngeal

conditions which necessitated the use of the larynx knife. There were several knives in use at that time, but for one reason or another they seemed inadequate, and I therefore endeavored to devise an instrument which would overcome these slight deficiencies. The knife in the accompanying illustration has proved most satisfactory. In addition to the knife, there is a silver nitrate carrier which allows one to apply the solid silver to the larynx.

A larynx knife and silver nitrate carrier.

without coming in contact with any other part of the throat, owing to the fact that the sheath slides over the carrier containing the small silver pearl.

This knife is intended to give to the laryngologist a practical and light instrument, which can be used with perfect safety in all intralaryngeal work. The instrument itself consists of four metallic parts which can readily be taken apart, thus making it simple and in no way cumbersome.

It has the advantages: 1. That it is light in weight; 2, being all of metal, can be easily taken apart and sterilized if desired; 3, the screw arrangement at the upper part of the handle permits one easily to regulate the length at which one desires the knife to protrude from the sheath, that is, if one wishes to make a deep incision or merely a superficial scarification; 4, the sheath moves back while the knife remains stationary, which is contrary to other knives, thus allowing the knife to remain directly over the part to which it is intended to be applied; 5, the knife recovers itself owing to a small spring on the handle; this is of great importance, as the knife is always protected, except when one pulls the sheath back, thereby increasing the danger of cutting the patient while the instrument is being withdrawn; and 6, the knife blade itself, which is about an inch in length, can be made

to cut in any direction, owing to a small screw arrangement at the lower part of the sheath.

57 EAST FIFTY-EIGHTH STREET.

## Letters to the Editors.

### MALARIA IN GREECE.

126 EAST THIRTY-FOURTH STREET,  
NEW YORK, April 25, 1908.

#### To the Editors:

In the issue for April 11th of the *New York Medical Journal* appeared my article under this heading. It was my intention to give a series of papers on the work done by our Greek brethren under the protection of the King of the Hellenes, and in cooperation with the Greek people to exterminate malaria in their country.

As stated in this paper, I took my information from the reports of the *Sylogos*, founded by Dr. Cardamatis to combat malaria in Greece, for the years 1905 and 1906. On reconsideration of the matter, I find that nothing short of a complete translation would do justice to the noble work presented in this report. In fact, it is more than a report, for it presents the state of our knowledge of the present day about malaria and the scientific measures against it, as executed in all different countries. Everything of scientific value that has been done and written is collected in a masterly way.

Such a version in English would serve great purposes; it would draw attention to the state of medical science in Greece and would be a means of enlisting our own people in the cause of exterminating malaria; it would aid in stimulating our authorities to support our own boards of health in their attempt to secure hygienic conditions, for instance, on Staten Island, where an immense amount of work has already been done, in order to make this beautiful island an earthly paradise; but, further, to stimulate the government and the legislators to assist in one of the greatest and noblest tasks the medical profession can suggest.

A. ROSE.

## Book Notices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

*Formulaire synthétique de médecine.* Par le Dr. L. PRON.  
Paris: Jules Roussel, 1908. Pp. 601.

The arrangement of this formulary differs from that of most compilations of its kind, where the formulas are grouped under the names of the drugs and one principal drug is combined in different forms for use in the treatment of a given disease. Dr. Pron's formulary prescriptions are grouped under the names of the diseases, or the applications for which they are intended, and different remedial agents are represented in the prescriptions. A good selection for formulas is given, and accompanying them are directions for administration, together with the doses suitable for adults and children. In addition to this there are chapters on diet, serotherapy, poisons and antidotes, uranalysis, mineral

waters, and incompatibilities, so that it is more than a mere compilation of formulas. The volume is of convenient pocket size, and should serve a useful purpose as an *aide-mémoire* for practitioners.

*Verhandlungen der deutschen laryngologischen Gesellschaft auf der ii. Versammlung zu Dresden, vom. 15.—18. September, 1907.* Herausgegeben im Auftrage des Vorstandes vom Schriftführer Dr. med. GEORG AVELLIS, Frankfurt a. M. Mit einem Titelbild und 2 Abbildungen im Text. Würzburg: Curt Kabitzsch (A. Stuber's Verlag), 1908. Pp. xiii-176.

These transactions of the second meeting of the German Laryngological Society, held in Dresden, contain, besides the official report of the meeting, many interesting essays. We find such names as Kuttner, Fränkel, Gerber, Heymann, Hoffmann, Krebs, Avellis, Sänger, Senator, Barth, Hajek, Panse, Kuhn, Rudloff, Rosenberg, Albrecht, Scherer, Blumenfeld, Imhofer, Mann, Keigler, Flatau, and Gutzmann among those of the authors. As an introduction there appears a memorial of Moritz Schmidt, the dean of German laryngology, who took a leading part in the tragic malady of the German Emperor Frederick III.

*Die tierischen Parasiten des Menschen.* Ein Handbuch für Studierende und Aerzte. Von Dr. MAX BRAUN, Professor der Zoologie und vergl. Anatomie, etc. Mit 325 Abbildungen im Text. Vierte, vermehrte und verbesserte Auflage. Mit einem klinisch-therapeutischen Anhang. Bearbeitet von Prof. Dr. OTTO SEIFERT in Würzburg. Würzburg: Curt Kabitzsch (A. Stuber), 1908. Pp. 623. (Price, \$4.)

The fourth edition of this standard work has been so changed that it appears as an entirely new book. The author gives first a short introductory chapter in which he speaks of the parasites generally, and to which he adds a chronological list of the more important books on helminthology (27 pages). This he follows up with the description of animal parasites of men (326 pages) and a bibliography (70 pages), which is arranged according to the chapters of the book. Finally we find an alphabetical index of the parasites described in the text, with their synonyms. Entirely new is the second part of this very interesting book, written by Professor Seifert, and containing a description of the diseases resulting from the parasites and their treatment (150 pages).

Although the book is rather larger, the arrangement in one volume seems to be very advantageous. The illustrations are very instructive. The German is written in short, precise sentences, which make the reading and understanding not at all difficult, while the price is not prohibitive. It is, in short, an up to date standard textbook which can be well recommended.

*Diseases of the Lungs.* Designed to be a Practical Presentation of the Subject for the Use of Students and Practitioners of Medicine. By ROBERT H. BABCOCK, A. M., M. D., until recently Professor of Clinical Medicine and Diseases of the Chest, College of Physicians and Surgeons (Medical Department of the Illinois State University), Chicago, etc. With Twelve Colored Plates and One Hundred and Four Text Illustrations. First Edition. New York and London: D. Appleton & Co., 1907. Pp. xix-809.

The high respect in which Dr. Babcock is held throughout the country will lead hosts of his professional brethren to rejoice that he has now supplemented his work on diseases of the heart by this one on the lungs. It is well that the original scheme of

dealing with both subjects in one volume of about 1,000 pages was abandoned, for, as the author says, such an arrangement would have proved unsatisfactory, since it would have called for such condensation as to diminish the practical value of the work.

In the preface Dr. Babcock says that he "awaits with considerable apprehension the criticisms to be passed upon the chapters devoted to pneumonia and pulmonary tuberculosis." We have examined those chapters carefully, and, as we had expected, we have found them exceedingly satisfactory, teeming with originality and good sense. Much care has been bestowed on the treatment of the various forms of pneumonia, and we would urge a careful reading of what the author says concerning the use of caffeine, camphor, musk, alcohol, nitroglycerin, oxygen, asafoetida, adrenalin, and bloodletting. In the chapters on pulmonary tuberculous disease equally sound views are expressed about the sterilization of milk, diet, climatic treatment, the employment of creosote and its derivatives, and the therapeutic use of tuberculin. Very properly, as we think, influenza is not treated of systematically, for it is not essentially or even preponderantly a disease that finds expression in pulmonary affections.

The book is written in Dr. Babcock's usual clear style, a style to which we find few exceptions, though he does use here and there the word "be-fallen" in a sense that is at least unusual, saying that a patient was or was not "befallen" with a disease. We are glad to see that he has not suffered his book to be disfigured with the "bobtailed" spelling: "hemorrhage" is hæmorrhage, and "quinin" is quinine. There seems to have been an omission of some explanatory heading from the table beginning near the foot of page 594; we guess that the numerals mean calories, but we are not sure. In the same table it is rather queer to find caviare listed under shell fish. From the mechanical point of view the volume is very praiseworthy, and in all respects it is most commendable.

*Mosquito Life.* The Habits and Life Cycles of the Known Mosquitoes of the United States; Methods for Their Control; and Keys for Easy Identification of the Species in Their Various Stages. An Account Based on the Investigations of the Late JAMES WILLIAM DUPREE, M. D., Surgeon General of Louisiana, and upon Original Observations by the Writer. By EVELYN GROSSBECK MITCHELL, A. B., M. S. Illustrated. New York: G. F. Putnam's Sons, 1907. Pp. 281.

The author is to be congratulated upon having produced a volume which will interest the lover of nature, and which also makes a direct practical appeal in the important relations which the subject has to preventive medicine. Much of the material is based upon the unpublished labors of the late Dr. J. W. Dupree, who found time, in connection with a large general practice and the exercise of many important functions as a public spirited citizen, to carry out numerous minute researches of value in entomology and bacteriology. The life history of the mosquito is considered in all its phases, and there are chapters on the relations of the mosquito to malaria, yellow fever, filariasis, and other diseases. Appended are identification keys and a systematic list which, with the anatomical studies included, will enable the reader to readily recognize the different species.

*Treatise on Diseases of the Skin.* For the Use of Advanced Students and Practitioners. By HENRY W. STELWAGON, M. D., Ph. D., Professor of Dermatology in the Jefferson Medical College, Philadelphia, etc. Fifth Edition, Thoroughly Revised. With 267 Illustrations in the Text, and 34 Full Page Colored and Half Tone Plates. Philadelphia and London: W. B. Saunders Company, 1907. Pp. 1150. (Price, \$6.)

Much new matter has been added in this edition of Dr. Stelwagon's admirable treatise, but the size of the volume has not been made appreciably greater, for some material has been dropped from the original work. There are thirteen new cuts and two new plates. The changes in the text are for the most part to be found in the articles on frambesia, Oriental sore, verruga peruana, and tinea imbricata. Several tropical skin diseases are newly treated of, prominent among which are "ground itch" (the dermatitis of uncinariasis) and "dhobie itch." The book continues to merit high commendation.

*Darwinism To-day.* A Discussion of Present Day Scientific Criticism of the Darwinian Selection Theories. Together with a Brief Account of the Principal Other Proposed Auxiliary and Alternative Theories of Species Forming. By VERNON L. KELLOGG, Professor in Leland Stanford, Jr., University. New York: Henry Holt & Co., 1907. Pp. xii-403.

To those, and they are not few, who glibly tell us that Darwinism is dead, that "the monkey theory" has passed to its eternal rest, this work of Kellogg's will come as a surprise, i. e., if they read it. For in it will be found a simple and concise account for students of biology, and for general readers, as well, of the present day standing of Darwinism in biological science, and an outline of the various auxiliary and alternative theories of species formation which have been proposed to aid or to replace the selection theories.

While no one doubts that the present time is one of unprecedented activity and fertility, both in the discovery of facts and in attempts to perceive their significance in relation to the great problems of biodynamics, yet in the very wealth of acquirement it often becomes difficult to decipher the understructures which support the more elaborate building. The knowledge of the factors of organic evolution, the hypotheses to which they have given rise, and the gaps which have been filled in the past few years have each and all been added to or modified, and only the specialist is able to keep clearly before the mind's eye the essential as distinguished from the trivial and accidental.

It is such a quality that renders this volume so useful and advantageous, and the reader who has been confused by the pros and cons of a never ceasing discussion may find in it some rest and satisfaction.

The author first points out very clearly that Darwinism and evolution are not the same. He then explains what is meant by Darwinism, and subsequently discusses the attacks made upon the theories, notably upon that of sexual selection. Chapters vi and vii contain a defense of Darwinism, while Chapters viii, ix, x, and xi discuss other theories of species formation. In the final chapter of the book the present standing of Darwinism is given.

"The living stream of descent finds its never failing primal source in ever appearing variations: the

eternal flux of Nature, coupled with this inevitable primal variation, compels the stream to keep always in motion, and selection guides it along the ways of least resistance. The guardian of this course is natural selection. Selection will inexorably bar the forward movement, will certainly extinguish the direction of any orthogenetic process which is not fit, that is, nonadaptive. Darwinism, then, as the natural selection of the fit, the final arbiter in descent control, stands unscathed, clear, and high above the obscuring cloud of battle." This is the author's contention. To determine how well it is supported, and to get a full view of the battle as it is waging, one should read the book. It is well worth while.

*Heart Disease and Thoracic Aneurysm.* By F. J. POYN-TON, M. D., F. R. C. P., London, Assistant Physician to University College Hospital and Physician to Out Patients at the Hospital for Sick Children, London, Late Medical Tutor and Medical Registrar to St. Mary's Hospital. London: Henry Frowde (Oxford University Press) and Hodder & Stoughton, 1907. Pp. 310.

It would be difficult to comprise in such a small compass more valuable material than is contained in this admirable little volume. The author, who is equally well known as a research worker and careful clinician, has succeeded in impressing the stamp of originality and new interpretation upon many familiar facts. As might have been expected from his collaboration with Paine, the pathology of rheumatic endocarditis is presented with special fullness. Myocardial affections also receive the attention which their growing recognition demands, and the newer subjects of the auriculoventricular bundle of His, the Stokes-Adams syndrome, heart block, and the different varieties of arteriosclerosis are adequately treated. The book is a model of condensation, attractive arrangement, and sound teaching, and may be warmly recommended as probably the best recent work of its kind for both student and practitioner.

*The Theory and Practice of Hygiene* (NOTTER and FIRTH). Revised and Largely Rewritten by R. H. FIRTH, Lieutenant Colonel, Royal Army Medical Corps, etc. Third Edition. Philadelphia: P. Blakiston's Son & Co., 1908. Pp. 993. (Price, \$7.)

Colonel Firth, of England, has edited a third edition of Notter and Firth's *Hygiene*, which appeared for the first time in 1896, based upon the late Dr. Edmund A. Parkes's work.

The changes made in this new edition are such as to make it practically a new book. One of the principal changes is the omission of the list of books of reference which formerly followed each chapter; the bibliography is now to be found in footnotes, and that arrangement we regard as a decided improvement. While in the former editions sanitary law took up a separate chapter, it is now discussed as far as possible at the end of each chapter. But two new chapters have been added: Sanitary Administration and Law (Chapter i), and Recent Sanitary Legislation (Chapter xviii), taking up such subjects of the law as would not be referred to in the general chapters. The chapter on Vital Statistics has also been materially changed.

Besides these major alterations, the book has been fully brought up to date, and is a worthy successor to the well received former editions. As it is based

entirely upon sanitary laws and statistics in Great Britain, it will not so much appeal on this account to the American reader, but there are many other points in it which are of general interest.

*Medical Diagnosis.* A Manual for Students and Practitioners. By CHARLES LYMAN GREENE, M. D., Professor of the Theory and Practice of Medicine in the University of Minnesota, etc. Second Edition, Revised, with Seven Colored Plates and Two Hundred and Forty-one Illustration. Philadelphia: P. Blakiston's Son & Co., 1907. Pp. 691.

Within the compass of some seven hundred pages of a book of convenient size, well bound in limp morocco, Dr. Greene has presented a manual of medical diagnosis which has many excellent features. The typographical arrangement of the work is admirable from the student's point of view, accentuating the important features in each of the statements made. The work is supplied with several colored plates, which add much to its value, showing the effects of stains and reagents in a manner more accurate and comprehensible than could possibly be shown by words alone. The marginal notes add much to the value of the work for ready reference. On the whole, the volume is one which has much to commend it, both as to the matter it contains and as to the manner in which it is presented, and we are by no means surprised to learn that a second edition was demanded within seven months of the issue of the first.

### Miscellany.

**Surgery Before the Days of Anæsthesia.**—Dr. W. C. Wood, of Gloversville, N. Y., sends us the following extract from *The Herald of the United States*, published by Nathaniel Phillips, at the Post Office in Warren, State of Rhode Island, Saturday, October 20th, 1792:

WARREN, R. I., October 20, 1792.

On Sunday, the 8th inst., Dr. Nathaniel Miller, of Franklin, in Massachusetts, performed a surgical operation in Barrington.

Mrs. Allen, the amiable Consort of Samuel Allen, Esq., having a Tumor on her left arm which had been collecting upwards of 20 years. The excrescence (by its bulk) had become troublesome; rational resolution stimulated her submission to the operation which was performed by Dr. Miller, in presence of Dr. Baylis of Dighton, and several other gentlemen of the faculty. The tumor was extracted by incision and weighed  $2\frac{1}{2}$  pounds. Before the operation began, a pertinent prayer was made by the Rev. Mr. Townsend, to the Author of Goodness for Divine countenance in the operation: After it was performed, a grateful acknowledgement was made to Heaven for its supporting hand.

Mrs. Allen sustained a fortitude highly becoming the principles of reason and decency.

Much credit is due to the skillful Gentleman in his surgical performance as well as his attention in the healing art—his patient is now out of danger from the extraction.

**Appointments of Reserve Surgeons.**—There exists some misapprehension among contract surgeons in the army in regard to appointments as reserve surgeons. It should be explained that there is no provision in the new medical law for allowances to contract surgeons who may become candidates in the Army Medical School. Therefore contract surgeons who wish to enter the school and are of the eligible age and have qualified by pass-

ing examination to enter it will be appointed to the reserve corps. Seventy-four candidates are enrolled for the examination to be begun May 4th for appointments as surgeons in the army. Last year at the similar examination there were but thirty-four candidates. All applications coming in now from intending candidates are placed on file for the examination arranged to take place beginning August 3d. The candidates who pass in either examination will be on the same footing, as all will be regarded as one class. Those who apply now or hereafter will need time to file their credentials and make ready for the examination, so that there is no material gain in being in the first examination. The relative standing of all examined at both examinations will determine seniority in appointment. There are now fifty-nine vacancies and to these will be added two more by retirements soon to occur. There are now ten members of the class at the medical school and these will receive the first ten appointments. After that the vacancies will be supplied from the successful candidates of the two coming examinations. Of the existing vacancies thirty-two were created by the new medical bill and twenty-seven are due to retirements and resignations.—*Army and Navy Journal*.

**A Great Society for Coping with the Emergencies of Peace and War.**—The National Volunteer Emergency Service, instituted in 1900, has recently been reorganized by the election of Dr. James Evelyn Pilcher, the distinguished editor of *The Military Surgeon*, as its director general, and Dr. F. Elbert Davis, of New York, as its adjutant general. Its work will be conducted along military lines, the details being worked out in three separate corps, a first aid corps, a public health corps, and a medical corps—the latter consisting of physicians, with rank from lieutenant to colonel, according to length of service, to whom are afforded special opportunities for emergency training. It includes among its personnel a large number of notable personages, and is rapidly extending its membership throughout the country. Full details regarding the service and its great work may be obtained by addressing Director General Pilcher at Carlisle, Pa.

**Medical Language.**—D. H. Zimmerer, of Regensburg, Germany, remarks in the *Journal of the American Medical Association* that the writings of Hippocrates, Aristotle, and Galen, as well as of Celsus, Pliny, and Vegetius, are, and will remain for all scientists, the basis and test for correctness of language, and purity of Greek and Latin terms in the domain of natural philosophy. Pollux, in his Greek *Onomasticon*, has stored up the existing supply of medical onomatology. It is by this means that these sciences still bear to-day the stamp of intercommunity, simplicity, and internationality, and this fact makes it an indispensable duty for every physician and natural philosopher to acquire a knowledge of these two languages. Without a knowledge of etymology, and the laws of word construction a linguistic expression will not be retained in the memory; it possesses neither sense, nor form, its relations and differentiations are unrecognizable and obscure, throwing the door wide open to arbitrary misconception and linguistic malformations.

## Official News.

Public Health and Marine Hospital Service  
Health Reports:

The following cases of smallpox, yellow fever, cholera, and plague have been reported to the surgeon general United States Public Health and Marine Hospital Service, during the week ending May 8, 1908.

### Public Health and Marine Hospital Service:

*Official list of changes in the stations and duties of commissioned and noncommissioned officers of the United States Public Health and Marine Hospital Service for the seven days ending May 6, 1908:*

CARMICHAEL, D. A., Surgeon. Granted leave of absence for fourteen days, from May 27, 1908.

DREW, A. D., Acting Assistant Surgeon. Granted leave of absence for thirty days, from June 3, 1908.

GARDNER, C. H., Passed Assistant Surgeon. Detailed as a member of a Revenue Cutter Service Retiring Board, to meet at San Francisco, Cal., May 12, 1908.

FOSTER, A. D., Passed Assistant Surgeon. Granted leave of absence for one day, April 16, 1908, under paragraph 191, Service Regulations.

HOBBS, W. C., Passed Assistant Surgeon. Detailed as a member of a Revenue Cutter Service Retiring Board, to meet at San Francisco, Cal., May 12, 1908.

HOLLAND, D. J., Acting Assistant Surgeon. Granted leave of absence for five days, from May 4, 1908, under paragraph 210, Service Regulations.

KEATLEY, H. W., Acting Assistant Surgeon. Granted leave of absence for one day, April 30, 1908, under paragraph 210, Service Regulations.

KERR, J. W., Assistant Surgeon General. Detailed to represent the service at the meeting of the National Association for the Prevention of Tuberculosis, to be held in Chicago, Ill., June 4 to 6, 1908. Also directed to attend the meeting of the National Association of the Milk Commission at Chicago, Ill., June 1, 1908.

McINTOSH, W. P., Surgeon. Directed to proceed to Vanceboro and other points in Maine for special temporary duty, upon completion of which to rejoin his station.

RYDER, L. W., Pharmacist. Granted leave of absence for two days, from May 6, 1908, under paragraph 210, Service Regulations.

STANTON, J. G., Acting Assistant Surgeon. Granted leave of absence for twenty-seven days on account of sickness, from April 4, 1908.

STUART, A. F., Acting Assistant Surgeon. Granted leave of absence for twenty-one days, from May 15, 1908.

WALKER, T. D., Acting Assistant Surgeon. Granted leave of absence for four days, from May 1, 1908.

WETMORE, W. O., Acting Assistant Surgeon. Granted leave of absence for one day, April 24, 1908, under paragraph 210, Service Regulations.

WILSON, J. G., Acting Assistant Surgeon. Order granting leave of absence for two days in March, 1908, amended to read for one day only.

#### Board Convened.

A board of medical officers was convened May 2, 1908, to meet at Seattle, Wash., to make physical examination of an officer of the Revenue Cutter Service. Detail for the board: Passed Assistant Surgeon M. W. Glover, chairman; Assistant Surgeon C. W. Chagnon, recorder.

### Army Intelligence:

*Official list of changes in the stations and duties of officers serving in the medical department of the United States Army for the week ending April 11, 1908:*

BROWNLEE, C. Y., Captain and Assistant Surgeon. Left Pacific Branch, U. S. Military Prison, Alcatraz Island, Cal., for duty as surgeon of the transport *Sheridan*.

GRISSINGER, J. W., Captain and Assistant Surgeon. Left Fort Ethan Allen Vt., on leave of absence for two months.

WILLIAMS, A. W., Captain and Assistant Surgeon. Relinquished leave of absence and will proceed to duty at Fort H. G. Wright, N. Y.

### Navy Intelligence:

*Official list of changes in the medical corps of the United States Navy for the week ending May 9, 1908:*

BECKNAP, J. L., Assistant Surgeon. Detached from the naval training station, Newport, R. I., and resignation accepted to take effect May 6, 1908.

COOK, F. C., Surgeon. Orders to the *North Carolina* revoked; ordered to continue duty at the Naval Academy, Annapolis.

JONES, A. McK., Acting Assistant Surgeon. Detached from the naval recruiting station, Des Moines, Ia., and resignation accepted to take effect May 1, 1908.

McGUIRE, L. W., Assistant Surgeon. Appointed an acting assistant surgeon from April 15, 1908.

McMURDO, H. B., Acting Assistant Surgeon. Appointed an acting assistant surgeon from April 15, 1908.

MILLER, J. T., Assistant Surgeon. Detached from the *Franklin* and ordered to the *North Carolina* when commissioned.

STRITE, C. E., Assistant Surgeon. Ordered to the *Franklin*.

WARNER, R. A., Assistant Surgeon. Detached from the *Naval Hospital*, Pensacola, Fla., and ordered to Washington, D. C., May 7, for examination for promotion and then to await orders.

## Births, Marriages, and Deaths.

#### Married.

HEILMAN—KIRK.—In Syracuse, New York, on Thursday, April 30th, Dr. Ralph Salem Heilman and Miss Laura Burns Kirk.

JUDY—RAIRDON.—In Piqua, Ohio, on Friday, May 1st, Dr. G. S. Judy, of Miamisburg, and Miss Ida E. Rairdon.

#### Died.

CALHOUN.—In Philadelphia, on Monday, May 4th, Dr. Edward Calhoun, aged thirty years.

CARMICHAEL.—In Trinidad, Colorado, on Friday, May 1st, Dr. Ahab K. Carmichael, aged fifty-four years.

CARTLEDGE.—In Louisville, Kentucky, on Monday, May 4th, Dr. A. Morgan Cartledge, aged forty-nine years.

CASWELL.—In New York, on Sunday, May 3d, Dr. William Halsted Caswell, aged sixty-six years.

CHRISTISON.—In Chicago, on Friday, May 8th, Dr. John Sanderson Christison.

CLARK.—In Lakewood, Ohio, on Monday, May 4th, Dr. William Clark, aged eighty-two years.

DRAPER.—In Kansas City, Missouri, on Tuesday, May 5th, Dr. James F. Draper, of Victor, New York, aged eighty-two years.

GAMBLE.—In St. Louis, Missouri, on Monday, May 4th, Dr. David Coalter Gamble, aged sixty-four years.

GUILD.—In Wheaton, Illinois, on Saturday, April 25th, Dr. Elias Cornelius Guild, aged seventy-six years.

HALL.—In Boston, on Wednesday, April 29th, Dr. Rufus H. Hall, of Everett, Massachusetts.

HOLMES.—In Adams, Massachusetts, on Sunday, May 3d, Dr. Horace M. Holmes, aged eighty-two years.

KIRCHNER.—In St. Louis, Missouri, on Sunday, May 3d, Dr. Henry Charles Albert Kirchner, aged eighty-seven years.

KUHN.—In Brooklyn, New York, on Thursday, May 7th, Dr. Louis Debarth Kuhn, aged seventy-nine years.

LEWIS.—In Farmer, North Carolina, on Thursday, April 23d, Dr. Claude H. Lewis.

LYONS.—In Fitchburg, Massachusetts, on Wednesday, May 6th, Dr. Herbert H. Lyons, aged fifty-three years.

McCoy.—In Independence, Missouri, on Wednesday, April 29th, Dr. Charles D. McCoy, aged fifty-six years.

McNULTY.—In New York, on Friday, May 1st, Dr. John Joseph McNulty, aged forty-five years.

MADDIN.—In Nashville, Tennessee, on Monday May 4th, Dr. John W. Maddin, aged forty-two years.

MADDIN.—In Nashville, Tennessee, on Monday, April 27th, Dr. Thomas L. Maddin.

PERRY.—In Worcester, Massachusetts, on Friday, May 1st, Dr. Charles Homer Perry, aged seventy-three years.

SCHLERETH.—In New Rochelle, New York, on Wednesday, May 6th, Dr. George Schlereth, aged sixty-four years.

SILBERT.—In Roxbury, Massachusetts, on Saturday, May 2d, Dr. Joseph J. Silbert, aged forty-three years.

STARRETT.—In Chicago, on Friday, April 1st, Dr. Carlton E. Starrett, of Elgin, Illinois, aged forty-four years.

TABOR.—In Cassopolis, Michigan, on Wednesday, April 30th, Dr. J. S. Tabor, aged thirty-three years.

WARRINGTON.—In Washington, New Jersey, on Thursday, May 7th, Dr. Charles B. Warrington, aged seventy-four years.

#### THE SIGMOIDAL FACTOR IN PELVIC DISEASES \*

By J. RAWSON PENNINGTON, M. D.,  
Chicago,

Professor Rectal Diseases, Chicago Polyclinic

*Relations and Influences.*—I was greatly impressed, when making some observations concerning the anatomy and physiology of the sigmoid and rectum in 1899 and 1900,<sup>1</sup> by the various lengths, positions, and adhesions of the sigmoid and of its relations to the pelvic viscera. In fact, I was so much impressed with these various conditions that I believed then, have taught since, and still contend, that an adherent, extra long, overfilled, or loaded sigmoid, particularly when it has an extra long mesentery, is more frequently than usually considered a potent factor in the production of many diseased conditions occurring in the pelvic viscera. Especially was I impressed with the possible pathological influences of such conditions on the uterus and its annexa; and, in this paper, shall confine my remarks to these relations and influences. Later I shall consider other phases of the subject. If the foregoing premises are true, then the treatment of cases of uteroovarian diseases caused by such conditions, should, it seems to me, be directed primarily to the sigmoid and rectum, and, secondarily, to the uterus and its annexa. But, you ask, what percentage of uteroovarian diseases are due primarily to sigmoid influences? Not being familiar with any statistics bearing on this subject I shall state that it is my opinion, based on the following clinical observations and autopsy findings, that quite a large percentage of such cases, a much larger percentage than you would imagine, are caused by conditions emanating from the sigmoid and its mesentery.

#### *Clinical Observations.*

1. It has been my observation that more than seventy-five per cent. of adult women whom I have examined for some rectal or sigmoidal disease have had, in addition to the bowel trouble, more or less uterine disorder.

2. In making proctosigmoidal examinations from one half to two hours after defecation, of young girls between the ages of sixteen and twenty-two years suffering from some form of uterine disorder, such as leucorrhœa, dysmenorrhœa, etc., I have found the rectum and sigmoid more or less filled with feces.

3. That *pari passu* with the relief and improvement of the rectal and sigmoidal conditions, in a large percentage of these cases, there will also be observed relief and improvement in the uterine troubles.

4. That when the sigmoid and uterus sustain normal physiological relations to each other and the former is loaded and unloaded periodically, then the effect of the sigmoid on the uterus is salutary. This is true, because the normal physiological position of the uterus is one of suspended mobility in an anteverted state, and such functions are physiological. But, on the contrary, if the functions of

FIG. 1. Diagram illustrating the normal physiological position of the uterus and sigmoid colon. The uterus is anteverted, and the sigmoid colon is in a coiled position, with its mesentery and its proximity to the uterus.

the sigmoid are compromised by adhesions or some other pathological or anomalous condition, then we should expect it to have a detrimental rather than a salutary effect on these organs, and that is what we usually do find. Again you ask, and quite pertinently too, What percentage of these cases have adhesions or some other pathological or anomalous condition of the sigmoid, and in what percentage of the cases does the sigmoid get loaded and unloaded periodically?

Byron Robinson (*Menstrual Stricture*, 1902) says that in 800 adult autopsies (400 men and 400 women) of which he has a record, that adhesions of the sigmoid were found in eighty per cent. of the men and in eighty-five per cent. of the women. Furthermore, every detumescence and every pro-

\*Read at the meeting of the Medical Society of the City of Chicago, May 15, 1907.  
From the Chicago Polyclinic, Chicago, Ill.

tor knows of the frequency of such adhesions; and every physician and most laymen are familiar with the prevalence of constipation.

**Autopsy Findings.**—The following illustrations (Figs. 1 to 10), made from autopsies, show that the

FIG. 2.—The sigmoid, *S*, is sustained by hooks, *H*. It was twenty inches long, partially filled with feces, crowded into the left side of the pelvis, forcing the uterus, *U*, to the right side and fixing it there. The left ovary, *LO*, was elongated, fixed by adhesions, doubled on itself, and bent downwards near *R*, mainly by the weight of the sigmoid. *M. C.*, age fifty-three. Autopsy, August, 1907. (Pennington.)

sigmoid may overlap, wind around, rest beneath or on these organs, and that it may be adherent at various points. Such conditions not only compromise its functions, but those of the uterus and its annexa.

The uterus, when sustaining such relations to a chronically loaded sigmoid, may be displaced up-

wards, downwards, laterally, backwards, or forwards, and held or fixed in that position. This interferes with its mobility and functions, hence produces a pathological state of that organ. If the uterus is continuously held or fixed in any relative position whatsoever, be that position anteversion or otherwise, and whether it be by tumors, an overloaded or adherent bowel, or what not, it must sooner or later become congested and the victim of infection.

The normal physiological position of one's hand, for example, is likewise that of suspended mobility, and when by his side is in a normal relative position. Yet it cannot be gainsaid that, if it be continuously maintained in that position, either by tying or any other means, it will, sooner or later, become congested and in a pathological state; so will the uterus if it be maintained permanently in any relative position.

This compromise of the mobility of the uterus places it under stress, and an organ under stress becomes turgescient, crippled, and is, therefore, not in a good condition or the best position to defend itself against the invasion of microbes. Along with

FIG. 3.—The sigmoid, *S*, is held up by a hook, *H*. This exposes the doubling up of the left oviduct, *LO*, and the downward bend and displacement of the right oviduct, *RO*. It also shows the position of the uterus, *U*, in the left side of the pelvis. (Pennington.)

this loaded and more or less fixed condition of the sigmoid there may exist sigmoiditis, mesosigmoiditis, or perisigmoiditis with adhesions. This further compromises the functions of the sigmoid, and it in turn thoses of the uterus. Such a compromised position of the uterus and its appendages is pathological and demands attention. But should that attention be directed primarily to the uterus and its annexa, or to the structures causing the trouble, i. e., to the sigmoid and rectum?

**Symptoms.**—Doubtless you will have anticipated that the symptoms arising from such complex conditions would be primarily from the sigmoid; and, secondarily, from the uterus, ovaries, and oviducts. But such is not the case. The man who steps on your toe, for example, is not the one that usually makes the first outcry. Yet he is the offender. Neither is it the sigmoid that necessarily presents the first symptoms, although it may be impinging on the uterus. As regards the relative time of the

FIG. 4.—The sigmoid, *S*, is held up by a hook, *H*. It is then the sigmoid, *S*, is held up by a hook, *H*. It then extended upwards, backwards, and outwards crossing the right broad ligament and oviduct, *RO*, and passing downwards behind these structures and the cervix, terminated in the rectum, *R*. It was bound down by adhesions, *A*, to the left parietal peritoneum. It completely filled the right side of the pelvis, displacing and fixing the uterus in a position of left lateral retrodeviation. The right fibromatous extremity was adherent to the parietal peritoneum, *A*, on that side. The right oviduct, *RO*, was elongated and bent downwards by the weight of the loaded bowel. *L. C.*, age forty. Autopsy, August, 1907. (Pennington.)

manifestation of the symptoms, it is, in the majority of cases, the uterus and its annexa to which complaints are first referred and for which relief is sought; and, frequently, not for a considerable length of time, indeed sometimes not at all, is the complaint referred to the organ that is the real source of the mischief. Among those symptoms emanating especially from the uterus may be mentioned leucorrhœa, dysmenorrhœa, metorrhagia, and menorrhagia, while those pointing directly to the bowel factor are constipation, an overloaded bowel with daily evacuations, painful defæcation, mucus in the stools, etc. Among those common to all the organs considered are hæmorrhage, nausea, sensation of weight in pelvic region, especially at the menstrual period, pain or pain and weight in the left or right groin, dragging pains in the iliac and lumbar regions, headache, lassitude, nervousness, tired feeling, etc.

The foregoing are the same clinical symptoms mentioned in our textbooks on gynecology and surgery, differing only in an attempt at classifica-

tion. The patient was referred to me by a confrère in May, 1905, to be treated for pruritus ani. Examination showed that she had proctosigmoiditis, was constipated, had mucus in her stools, pain in her left side on palpation, leucorrhœa, dysmenorrhœa, a retroverted and very sensitive uterus, and great tenderness over both ovaries and oviducts. Many weeks of topical applications to the uterus had given her no relief.

FIG. 6.—Same as Fig. 5. Here the sigmoid, *s*, is elevated by a hook, *h*. The mesentery, *m*, was six inches long. (Pennington.)

FIG. 5.—The sigmoid was eighteen inches long. It descended into the left side of the pelvis, and the air-tissue between the bladder, *b*, and uterus, *u*; then ascended upwards, crossed over the fundus of the uterus, *u*, and descended behind this organ to the rectum. The uterus was in a position of right lateral retrodeviation and greatly displaced downwards in the pelvis. *M. G.*, age fifty. Autopsy, May 5, 1907. (Pennington.)

tion. Patients with such symptoms usually seek relief for the uterine and ovarian trouble only. They regard the symptoms which are especially associated with the bowel factor as of little or no importance. Even the consulted physician frequently fails to realize the value of this factor. Why? Because, 1, he seems to forget the anatomical and physiological relations existing between the rectum and the sigmoid and the uterus and its annexa; 2, he rarely, if ever, examines the rectum and sigmoid in cases of uteroovarian diseases except in a perfunctory manner. It is obvious, therefore, that the conclusion reached by such an examination is faulty.

To properly interpret the array of symptoms arising from these closely related organs (the rectum and sigmoid, and the uterus and its annexa) necessitates a careful examination of each; and if the rectum and sigmoid are found in a condition that would modify or interfere with the functions of the uterus and its annexa that condition should be treated.

The following case emphasizes the importance of this assertion:

CASE I. Miss W., of Princeton, Ill. age twenty years,

Part of my treatments consisted in colonic lavage combined with manual massage. This produced quite a little pain, especially on the left side. I repeatedly requested her to consult a gynecologist, because of her uteroovarian trouble. Finally, of her own accord she consulted one of the leading internists and one of the most eminent gynecologists in the city. Each, according to her report, said her ovaries would have to be removed. I then had another gynecologist examine her. He confirmed their diagnosis and advised the same surgical procedure. She declined the operation. I continued my treatment. One day on leaving the office she said she had a sensation as though something broke loose within the abdominal cavity. From that day on colonic lavage was painless, her bowels improved, and her leucorrhœa soon became notably less. While there is still some thickening of the broad ligaments and some slight tenderness over the tubes and ovaries, yet she has had no dysmenorrhœa nor leucorrhœa, and her bowels move regularly daily. I have often thought since finding

FIG. 7.—Sagittal view of the female pelvis showing the sigmoid colon (S) and uterus (U). The diagram is labeled with 'B' for bladder, 'S' for sigmoid, 'U' for uterus, and 'R' for rectum.

the specimen shown in Fig. 10 that she likewise had an adherent appendix epiploic and that it was the breaking of this band which she felt.

**Diagnosis.**—Here again we are confronted with the same complicated proposition as when we attempted to write the symptomatology. To make a diagnosis in a case of suspected uteroovarian disease, or in one presenting the foregoing symptoms, it is as necessary to make a complete and thorough rectal and sigmoidal examination as it is to make

FIG. 8.—The sigmoid, *s*, was twenty-eight inches long. It passed down the left side of the pelvis to the bottom of the cul-de-sac in front of the uterus; then across the front of the uterus, *u*, to the right side of the pelvis, then upwards and backwards over the right oviduct, then slightly upwards and towards the left side, until it passed beyond the median line, then curved to the right and downwards behind the fundus, then curved to the left behind the uterus and passed beyond the left border of that organ, then crossed again to the right and passed across the bottom of Douglas's cul-de-sac to terminate in the rectum, *r*. The sigmoid thus practically surrounded the uterus; *ls*, is the right loop of the sigmoid; *e*, is the left loop; *a*, adhesions to the parietal peritoneum; *r*, rectum. The ovaries and oviducts were purposely omitted from this sketch. R. B., age fifty years. (Autopsy, October, 1905. (Pennington.)

a complete and thorough uterine examination. The former, as a rule, should be made first. Especially is this true in the case of young girls and unmarried women, as this examination may give sufficient information without making the latter. If not, then the uterine examination should be made by the usual "touch" bimanual and instrumental means.

One of the objects in making a rectal and sigmoidal examination is to ascertain whether or not the sigmoid and rectum are emptied and refilled periodically. An individual may defecate regularly every day and yet have a continuously loaded bowel. Such a condition may interfere with rhythmic uterine action, and if not corrected cause a pathological state of that organ. Hence the necessity and importance of proctoscopy, sigmoidoscopy, palpation, etc., when making such examinations. It is not necessary for the uterus to be pushed to one side or down in the pelvis and held there, as shown in some of the foregoing illustrations, to become pathological. It is a movable organ, and its position is one of suspended mobility. Anything, therefore, that immobilizes it continuously, it matters not what the relative position of the uterus may be, compromises its functions with a pathological sequence. A persistently loaded sigmoid and rectum may produce this pathological sequence. If the patient has fibrosis of the rectal valves, chronic hypertrophic or atrophic proctosigmoiditis, contractions, strictures, kinking, adhe-

sions, or an extra long sigmoid or mesentery or other conditions interfering with the regular rhythmic loading and unloading of the sigmoid and rectum, she, in the course of time, is most likely to have leucorrhœa, dysmenorrhœa, and other symptoms pointing to the beginning of a pathological state in her genitalia.

The mere statement of a patient that she is not constipated because her bowels move once or twice daily is not to be accepted as conclusive evidence that she has not an overloaded bowel. In fact, when a patient states that her bowels move twice daily and that both movements are close together, I usually expect and do find a continuously filled or diseased bowel. To illustrate:

**CASE II.**—A lady was brought to my office in April, 1905, by a former patient seeking, through me, the services of a gynecologist. Believing from her statement that her bowels were more in need of treatment than her uterus, I made a rectal examination after she had assured me that she was not constipated, that her bowels had moved twice that morning, and that she had never had any trouble of any kind whatsoever with them. On removing the obturator from the proctoscope I found her rectum loaded with feces. I requested her to return home, cleanse her bowels with injections, and return the following morning for examination; this she did. She expressed great surprise on entering my office the following day at the amount of material she had passed as the result of the injection; but for the same reason as on the previous day it was impossible to examine her. This was repeated for three successive mornings. On the fourth morning her husband accompanied her and assured me that her bowels were clean this time because he had attended to the matter himself. On removing the obturator from the speculum her uterus was very much chagrined to find that they were not as yet clean.

FIG. 9.—The same case as Fig. 8. The sigmoid, *s*, is lifted up by the hook, *h*. The uterus, *u*, is pulled downwards by the hook, *h*. *w* is a white fibrous line in the mesentery over the psoas muscle; *a*, *p*, adhesions binding the sigmoid to the psoas; *a*, adhesions causing an angulation of the sigmoid; *a*, *a*, adhesions between the appendix and fimbriated extremity of the right oviduct, *r* o, left oviduct; *r*, rectum. (Pennington.)

Vaginal examination in her case showed the uterus to be slightly anteverted and very sensitive, and the ovaries and tubes very tender.

I treated her with lavage of the colon combined with manual massage, and through these measures either stretched or broke up some adhesions which I believed I had detected. At least the pain in her left side, her leucorrhœa, dysmenorrhœa, nausea, and "tired feeling," etc., all

disappeared, and her bowels became quite regular, moving once daily.

**Treatment.**—Here again we are confronted with very much the same difficulty that we were in attempting to write the symptomatology and diagnosis, i. e., a dual proposition.

From the foregoing it would seem that the treatment of many pelvic diseases should be directed primarily and early to the sigmoid and rectum, and secondarily to the uterus and its appendages.

To treat, for example, a uterine disorder due to sigmoiditis, mesosigmoiditis, or perisigmoiditis, or to hypertrophic or atrophic proctosigmoiditis, fibrosis of the rectal valves, or to a continuously overloaded bowel, etc., by topical applications and vaginal tampons is not only useless, but *positively harmful*. Such treatment of this class of cases allows the condition to advance and leads to the later stages of pelvic disorders which necessitates more severe and radical measures. Doubtless it was the result of such treatment that caused Dudley to say in his most excellent textbook on *Gynecology* that "topical applications should be consigned to the archives of gynecology." In such cases topical treatment seems to benefit the patient temporarily; but, as a matter of fact, the condition continues to grow worse and worse until finally hysterectomy, oophorectomy, salpingectomy, or hysterosalpingo-oophorectomy, with their deplorable sequences, have to be performed.

If the conditions causing these troubles have advanced to that stage where they can not be corrected by simple methods and general tonic treatment, then laparotomy should be performed; not, however, for the purpose of removing the tubes and ovaries, but to apply such surgical measures to the offending sigmoid, as may seem indicated. Incidentally, of course, any requisite operative work on the uterus, tubes, and ovaries should be done at the same time.

The following case (Fig. 11) serves to illustrate the point in question.

Miss L., aged twenty-five, was referred to me by Dr. Gratiot, of Mineral Point, Wis., May 2, 1905.

FIG. 11.—The sigmoid is the colon, S, sigmoid is a hook, A, pulled down by a hook; A, adhesions between the sigmoid and parietal peritonium; B, adhesions between the broad ligament and the sigmoid; C, cervix; LO, left ovary slightly pulled down by a hook; U, uterus. (Pennington.)

She gave a history of inflammation of the bowels the previous February. She was a typical neuroasthenic, had lost twenty pounds in weight, had fibrosis of the rectal valves, proctosigmoiditis, and was constipated. Her left ovary and oviduct was tender, and she suffered from leucorrhœa and dysmenorrhœa. Proctocolostomy, lavage with manual

massage, and general tonic treatment gave her some relief only.

She returned December 14, 1905; conditions about the same as when she first consulted me. Laparotomy exposed adhesions of the sigmoid to the broad ligament and parietal peritonium on the left side, which confirmed my diagnosis. These were severed and the raw surfaces covered. Her improvement was very marked. Bowels became quite regu-

FIG. 12.—The sigmoid is the colon, S, sigmoid is a hook, A, pulled down by a hook; A, adhesions between the sigmoid and parietal peritonium; B, adhesions between the broad ligament and the sigmoid; C, cervix; LO, left ovary slightly pulled down by a hook; U, uterus. (Pennington.)

lar, leucorrhœa, dysmenorrhœa, and tenderness over ovary and oviduct disappeared. She has returned three different times since the operation because of the beginning pain in the left side. After a few treatments with lavage and manual massage the pains disappeared and she returned home feeling quite well again. She has had no leucorrhœa or painful menstrual periods since the adhesions were broken up. Her bowels have not improved so as to move regularly every day without some little assistance; yet, there is a marked improvement over her former condition and the uterine and ovarian trouble have entirely disappeared.

It seems to me that we are approaching a position from which we can view the treatment of pelvic diseases in a different and broader light. In the treatment of pelvic diseases early diagnosis and treatment is quite as essential to permanent success as is early diagnosis and treatment of cancer of the stomach, as advocated by W. J. Mayo.

There is probably a period in many cases of this class of pelvic disorder at which if taken they could be easily managed and successfully treated without surgical procedures. If not properly handled at that time then early surgical interference to break up adhesions, straighten out kinks in the sigmoid, especially the one that so frequently occurs at the rectosigmoidal junction, shortening or kinking in the mesentery, sigmoidopexy, "short circuiting" the bowel current, by lateral anastomosis, and, if need-

be, resection of the sigmoid should be done with the hope of preserving the genitalia and womanhood.

Should all of these measures fail, then, as a *dernier ressort*, hysterectomy, salpingectomy, oophorectomy, or hysterosalpingo-oophorectomy may have to be performed.

103 STATE STREET.

## THE RESTORATION OF THE NORMAL BALANCE OF THE FOOT.

### II.

#### *Second Paper. The Treatment of Weak or Flat Foot by the Use of a Mechanical Support.*

By E. G. ABBOTT, M. D., AND H. A. PINGREE, M. D.,  
Portland, Me.

The term weak or flat foot is here employed to designate that condition of the foot in which the arch is depressed, but in which the joints are freely movable in all directions. The complications of

The use of a support or plate in a shoe for the purpose of lifting the arch of a weak foot into a normal position and holding it there is not unlike in its effect that produced by the application of a brace to any part of the anatomy, and atrophy of the soft tissues with a corresponding weakness is the result. As the muscles which should maintain the arch in

FIG. 23.—Plaster cast of arch of skeletal foot, showing dome shape.

flat foot are already weak, it is very evident that such treatment alone, if the result sought is complete restoration of the normal, is not only inadequate, but unscientific.

The plate is useful during a certain stage in the treatment of weak foot, but should only be used as an agent in bringing the foot to a normal condition; and in order to do this it must be of such a shape that it makes little or no pressure when the foot is in activity, acts as a reminder to the patient to hold the arch in a proper position when the foot is passive, but supports it when he is unable to do so longer.

The best idea of what should be the correct form of support can be obtained by an examination of the contour of the arch in a dissected normal foot (Fig. 22), by an analysis of the motion of the foot when used in walking, and also from the attitude in weight bearing. A look at the plaster model of the skeletal foot will suffice to show that the arch is not an inclined plane, but that it resembles a section of a dome (Fig. 23), and therefore that, in order to maintain it in a normal position, the support must be dome shaped. The model also shows that the highest part of the support should not be at its inner margin, but at a point on it which corresponds with that part of the foot beneath the scaphoid bone and situated at some distance from its internal border. A support of this form, then, with slight allowance for the soft tissues, would just fit the arch of the normal foot, when the patient is standing, without making any considerable pressure. The parts of the foot which would support the body weight on the surface beneath it, rather than on the

FIG. 22.—Portion of dissected foot hardened in formaldehyde, showing shape of arch.

rigidity and inflammation which frequently accompany this deformity are not considered in this paper, since, as already stated in the introductory article on this subject (see *Journal*, p. 875), the treatment of them is necessarily preliminary to that of restoring the arch to its normal position, and a support, if of any value, does not fully serve the purpose for which it is intended until all restriction to motion is removed.

Also all such treatment as strapping or braces is not included, as that likewise is a preparatory measure. The use of proper shoes is here indicated, just the same as it is in the normal condition of the foot, and has only a relative bearing upon this part of the subject.

FIG. 24.—Footprint of a normal foot, showing weight-bearing surfaces.

plate, would be the heel, the outer margin of the sole, and the ball (Fig. 24). These would also be the parts which would successively support the body in walking, and such a plate would have no action

25

26

FIG. 25.—Plates ready-made, such as are sold in shoe stores.  
FIG. 26.—Usual type of plate made from a cast of the foot.

whatever on the normal foot either during motion or at rest.

Now, if a support of this shape is placed beneath a weak foot, it will be found that the arch is raised to a normal position, and that it remains there with very little pressure upon the plate even in those cases where the relaxation is extreme, notwithstanding that very little or no effort is made by the

27

28

FIG. 27.—Plate with heel and ball raised, designed to support the arch.  
FIG. 28.—Whitman plate, as made by Dr. J. B. Whitman, New York.

patient, as soon as he tries, to hold the arch by muscular power, for, as shown in the preceding paper, it requires only one-eighth as much force to maintain the arch, when it is raised to a normal position, as that necessary to lift the weight of the body, and this in the endstage, the most lax condition obtainable.

In walking, this support has no more action in the flat than in the normal foot, with the exception that it does remind the patient to place the foot in a correct position, so that the step may be properly taken. It makes no difference in the action of a plate of this shape whether it is placed in a shoe or upon the floor, where all restrictions are removed, the arch is maintained in its normal place and the foot must assume the correct position.

The arch is such, then, in its contour that, if a plate is so constructed that it conforms to it, it needs nothing whatever to prevent the foot from slipping off from it in any direction, it has very little action as a direct support until the patient tires, it acts as a reminder to the patient to hold the arch in a normal position, and it prevents the foot from assuming anything but a normal attitude during the successive movements of the step.

The different supports now in use all resemble in a general way the inclined plane, but, as they

FIG. 29.—Position of a weak foot on the Whitman plate as soon as muscular relaxation takes place.

differ somewhat in particulars, a brief description of them will be necessary in order to understand their action.

The one in most common use is that found in shoe stores (Fig. 25), and it is a type familiar to all. The highest part is the border which extends along the inner margin of the foot, and the plate's upper surface slopes concavely downward from this line to its opposite edge. It is made from a stock pattern, and is practically worthless. It is needless to mention the reasons why it does not accomplish its purpose.

The next most frequent shape met with resembles the ready-made plate with the exception that it is fitted over a cast of the foot (Fig. 26), and therefore conforms much better to the surface beneath which it is intended to be placed. The effect, however, is wholly to raise the inner border of the foot near the centre by resting it upon an inclined plane. The support cannot do this unaided, therefore the

boot must prevent the foot from sliding if the plate is to be held in place. It is at its best only a prop to the internal border of the arch, held in place by the boot; its action as a curative agent is practically nil, and it is probably more detrimental than useful to a proper gait.

In some instances the outer border of the plate

FIG. 30. Lateral view of a plate.

is turned up so that the foot is prevented from sliding from it (Fig. 27), and in this case the foot rests in a curved trough with the inner border higher than the outer.

The Whitman plate (Fig. 28), which is much superior to the supports described in the preceding,

FIG. 28. Whitman plate, showing the foot in shape.

and which marks a period of pronounced advancement in the mechanical treatment of weak foot, differs somewhat from the others both in its action and shape. It covers less of the foot on its under surface, but more on its inner, and has one outer flange just below the external malleolus. It is,

however, an inclined plane, and apparently the greater part of its action is due to this.

The so called positive action of this support is described as follows: The patient is instructed to throw the body weight on the outer side of the foot, as by so doing the foot presses against the flange on the outer side of the plate, tilting it. This causes the internal border of the support to be raised and pressed against the inner surface of the foot, which is instinctively drawn away from it.

It would seem from the description and from an examination of the plate in use that this positive action consists chiefly in causing the patient to walk on the outer side of the foot, provided he follows instructions. The lateral pressure voluntarily made on the outer flange of the support certainly raises its internal border, but by this action the border is raised throughout its entire length and carries as a whole the inner part of the foot with it. If the foot is placed upon this support it will be found that the posterior part, or heel, is held on an inclined plane by the outer flange, but that the whole anterior portion is free and cannot be held in the correct position unless the weight is thrown on the outer side of the foot, and then only through considerable effort upon the part of the patient. That this position cannot be maintained for any considerable length of time is evident, for, as soon as the patient tires and the muscles relax, the anterior part of the foot slides from the plate (Fig. 29).

The statement made by the supporters of this plate is that its action differs in principle from that of other forms, first, in that it supports the arch by lateral pressure over the inner surface of the foot, thereby preventing bulging of the internal border, which is the most important element of the deformity; second, in that the foot is under much less restriction and consequently its action is more like that of the normal foot.

It would seem from observations and experiments that the inner bulging of the foot, as already stated, is due wholly to a depression of the arch, and instead of being the most important element of the deformity, that it is only a result of this depression, and disappears at once as soon as the arch is restored by a proper support (see Figs. 7 and 8). It is possible for this plate through pressure along the inner surface of the foot to cause the patient to hold the foot for a time in a correct position by muscular effort, but, as soon as relaxation takes place—and,

FIG. 29. Showing position of a weak foot with plate placed beneath it.

if it did not, there would be no need of a support—the problem is one of simple mechanics, and just the same as that presented when an arch of similar shape of any material needs support. In such a case it would be necessary to do something besides securing one end of the arch and then making pressure against one side of it, with the other end entirely free.

The frequent assertion that the foot has more freedom in this support appears to be open to discussion. In the normal foot the arch movement is slight, and in all other motions which the foot has it moves as a whole, and any plate should not restrict these. It is a fact that this support covers less of the under surface of the foot than any other, but how much motion takes place in that part of the normal foot which would be left by such a plate? With this support the heel is firmly fixed and the rest is free, but the freedom is all in the direction of deformity, and it would seem that movements normal to the foot are less restricted by the ordinary plate.

In order to construct a support which shall meet the requirements in weak foot it is a well recognized fact that a model which conforms to the shape of the skeletal foot, at least approximately, is necessary. To obtain this by merely making a cast of the foot is impossible, as the soft parts cover it unevenly, and such a cast must necessarily be inaccurate. It might seem that the support would hold the bony framework in normal position if it conformed to the normal surface of the foot in the living subject, but experiments show this conception to be false, as some parts are covered with tissues which are resistant, while others are yielding and easily become absorbed under pressure. The best that we can expect to obtain is a model which conforms to that part of the bony framework which holds the body weight when the normal foot is used as a support. The modelling of the arch must be done with a knife, and the amount to be removed, as well as the shape, must be determined by judgment based upon experience.

There are several kinds of materials for making models, wax, paraffin, dental gum, lead, and plaster of Paris. The last named is most frequently used and upon the whole is considered the most satisfactory. The position in which the foot should be placed when the model is made is a question somewhat in dispute, and the best way to arrive at any conclusion as to the superiority of one over others is to analyze, step by step, the methods employed in taking the cast, of which there are two in common use, and compare the advantages offered by the supporters of each.

In the first method the model is made with the foot at rest, i. e., without being subjected to muscular action or weight bearing; by the other it is made with the foot approaching, if not quite in, the state of active support.

If the first method is used, i. e., a model taken with the foot at rest, the patient is seated with the leg flexed and the thigh rotated outward, so that if the foot is put upon a chair in front of him, it will rest upon its outer border and external malleolus. Plaster is then mixed to the proper consistency and poured upon a pane which is placed upon the thigh, and the foot is allowed to sink into it until about

one half of its surface is covered. As soon as the plaster sets, its upper margin is smeared with a lubricant and more plaster is spread over the remaining exposed part of the foot. This portion is then allowed to harden, after which it is removed, the foot taken out, the two parts placed in apposition again and bound together with a bandage. This mould, well oiled inside, is now filled with plaster porridge, and, as soon as it sets, the outside is removed and the model of the foot is the result.

A cast of the foot by the other method is made as follows: The patient is seated in a chair which is of just the right height, so that, when the legs are flexed to a right angle with the thighs, the foot will rest easily upon the floor. Some plaster having been mixed in a shallow pan and placed in front of the patient, the foot is grasped firmly around the ankle by one hand and around the toes by the other and held in a correct position, while it is pressed strongly against the bottom of the pan.

The foot is removed as soon as the plaster sets, and, after lubricating the impression, it is filled with plaster broth. The following day, or as soon as the broth has hardened thoroughly, the outside is broken away with a hammer, leaving the model.

As already stated, either method gives a model which is inaccurate, and which, in order that a plate may be constructed from it which will be efficient, must be carved with a knife, as the judgment indicates; but, as these two processes are the best that have so far been devised, it is necessary to choose between the two.

It is asserted by those who use the model made with the foot at rest that the arch is held by gravity in the best position obtainable, and that therefore it is the better method. If it is the purpose to get a cast of the foot with the arch placed apparently in the highest position possible, regardless of the normal when in use, this would undoubtedly be the method of choice. The arch in the normal foot, however, assumes a shape, when at rest, very different from that when it is used as a support, therefore the normal position of the arch with the foot at rest is not the normal position of it as a support, consequently a plate made from such a model will not even allow the arch of the foot to assume a normal position when in use.

Another disadvantage of this method is this, that the ball of the foot is quite likely to be on a different plane from that of the heel, and the arch is thereby twisted.

When the model is taken with the arch held in the normal position of support, and is subjected to pressure similar to that when the foot is in use, these difficulties are overcome and the cast represents more closely the shape of a normal foot in weight bearing.

It would seem, consequently, to support the first method, as the patient is free for the purpose of instructing the doctor as to what is wrong, whether by compression through the weight, or by the action of the foot in the correct position, or by direct pressure, that it should be done, and a model of that foot taken in a normal position, and subjected to a pressure like that of a normal foot when in use, rather than from a model of the same foot at rest, with the arch surface distorted, and in a position where it cannot be corrected.

The usual objection raised to taking a cast by holding the foot is this, that it cannot be held in a normal position, and, therefore, that it is most inaccurate. It is certainly not so difficult a procedure to hold a foot in a normal position in a pan of plaster as it is to hold a foot in a normal or over-corrected position while it is being fixed by plaster of Paris bandages, after breaking up adhesions of the joints.

If the model of the foot is correctly taken and afterward properly carved, a plate made over it should hold the foot in a natural position, or in the same position as the normal foot is held, when it is used as a support, and the best test of the value of a plate in the condition of weak foot is this, that, when it is placed under the arch, it makes very little if any pressure when the patient is standing, as long as he is able to hold the foot in a normal position, and none whatever when he is walking, but does support the arch in normal position unaided by a boot when the patient fails to do so by muscular action.

The changes which are made by the knife should commence with the impression before it is filled. The skeleton shows that the first metatarsal bone is freely movable and placed on a lower plane than the second, therefore the impression should be cut out along that part of it which corresponds to that bone, for, by so doing, it will be possible to trim the inner border of the cast more easily, so that it will be on a lower plane than the middle. The model should also be carved to correspond to the shape of the skeletal foot, and the lines for the support marked on its surface as follows: Beginning on the inner side of the heel just in front of the tuberosities of the calcaneum, a line is drawn curving backward to a point near the outer margin of the cast, thence along the outer border of the sole to a point just behind the head of the fifth metatarsal bone, thence over the ball of the foot to a point beneath the head of the first metatarsal bone, thence backward beneath this bone to the scaphoid where it curves inward and upward for a short distance, then backward and downward to the first mentioned point under the heel (Fig. 30).

The plate, when made, should resemble in shape the section of a dome, with the exception of the slight extension which controls the scaphoid bone (Fig. 31).

If a plate is made over such a model as described and along the lines indicated, it will be found upon trial that the foot rests easily upon it without the slightest tendency to slip from it, and this without the aid of a shoe; that anything but a normal step cannot be taken; that the foot is held in the corrected position, when used as a support, either through muscular action, which is the most agreeable method for the patient, and is maintained as long as he is able, or, as soon as relaxation takes place, by direct pressure (Fig. 32).

The whole action of such a support may be summed up as follows: Whether the foot is used in walking, or as a support in standing, it is not only prevented from assuming anything but a normal position, but there is a decided tendency for the foot to assume this normal position through muscular effort.

## MUCOMEMBRANOUS ENTEROCOLITIS. ITS CAUSES AND MECHANISM.

By H. NEPPER, M. D.,

Paris, France,

Assistant at the Department of Physiology, Hautes Etudes, Collège de France.

The proper definition of mucomembranous enterocolitis is: A symptomatic complex of very slow and chronic evolution characterized by constipation, mucomembranous secretions, and pains. These pains are of variable intensity and localization, and are of no great import in the aetiology of the disease; they only indicate that the intestines are in a state of irritation; they are common to numerous affections. Therefore only two signs remain of the three symptoms: Faecal stasis and the presence of coagulated mucus in the stools.

It is not my intention to speak of the symptomatology of this disease; I only wish to throw more light upon its pathology by reporting the results of some new experiments.

*Ætiology*.—I shall simply enumerate the predisposing causes, as they are usually stated: Arthritis, both hereditary nervous and neuro-arthritis; social position; adult age; female sex, etc. As occasional causes are cited: Defective alimentation; sedentary life and its usual consequence, constipation, etc. Other causes given are: Hæmorrhoids; intestinal polyps; abdominal tumors; utero-ovarian lesions; floating kidney; and enteroptosis. Finally, not to mention such causes as a chronic cold, we must include cases where chronic colitis was the sequela to acute colitis, dysentery, peritonitis, and typhoid fever.

*Pathology*.—Persistence of the symptoms, pains, faecal stasis, and mucomembranous stools does not imply, or rather did not imply, a specific process to be attributed to a casual agent which was always the same. Different theories, therefore, have been put forward which I shall shortly state: 1. The theory of infection; superficial infection of the mucous membrane attributed to the *Bacillus coli*, *Bacillus fluorescens*, *Proteus vulgaris*, and the *Diplococcus of Thiercelin*, the virulence of which is very much increased by faecal stasis and mucous oversecretion. 2. The theory based on nervousness. The phenomenon of colitis is said to be due to purely nervous troubles. 3. Mathieu believes it to be a reflex action of a short or a long circle, and at the same time a superficial inflammation with mucous oversecretion and cellular desquamation. 4. Finally we must remember the theory of enteroptosis proposed by Glénard, and the theory of Robin, who declared it to be a syndrome subordinate to a gastrophæræsthetic condition.

I cite these theories without discussing them, and wish to merely state that "although each of these pathogenic theories enables us to explain a certain number of cases, we cannot any longer say that a single one among them explains all these cases, nor can we say that all neurasthenics, that everybody whose intestinal mucous membrane is the seat of scarifying noxious substances, or that all women affected with one of the many symptoms of ptoses or with any other uterus or annexa lesions, are suffering from mucomembranous enterocolitis." I, furthermore, wish to call attention to the follow-

ing particularly: All the causes which were given have one common point of action, all theories proposed have the same basis, that is an action upon the liver. Every noxious influence, indeed, on the gastrointestinal apparatus reacts upon the liver. Let us remember the vasoconstriction reflexes exerted upon the liver by excitation of the general sensory nerves, the visceral, the distribution of these reflexes, their mechanical effects, their intervention, when poisons of whatever origin pass through the liver, and finally the analogous mechanism of psychic influences. All these causes have a tendency to diminish the functions of the hepatic gland.

After this remark let me close the discussion of the various theories and again consider the two principal symptoms: The fecal stasis, and evacuation of mucus; and let us find out their causes.

*First Part.*—Evacuation of mucus. This excretion must be preceded by two phenomena: 1, secretion and, 2, coagulation.

a. Secretion of mucus.—This secretion, or rather oversecretion (because it is evident even when only superficially examined), is dependent on the sympathetic excitement which may result from many causes; irritation through the presence of a fecal mass; elimination of toxic substances; nephroptosis; hepatoptosis; enteroptosis, which is very often overlooked; salpingitis; psychical or any other cause. It is, therefore, only a phenomenon of a small reflex.

But the fact of a mucous secretion does not necessarily imply excretion, and, what is still more, coagulation.

b. Excretion of Mucus.—Normally the mucus necessary to digestion is secreted in great abundance throughout the intestinal canal, and is then absorbed in the large intestine, with the exception of some small amount, which is found mixed in the matter which escapes absorption. Pathologically the excretion of the mucus is easily explained when the digestive passage is much abbreviated, as is the case in dysentery in the tropical countries, in which disease the mucus has not the time to be absorbed. On the contrary, in all cases of mucomembranous enterocolitis, where the fecal stasis is the main characteristic sign, the digestion is always slackened and slower than in the average normal cases, according to the case itself. The offhand explanation of excretion in a case of dysentery is therefore of not much account, and to be logical we must conclude that the mucus is the better and the more completely absorbed the longer the fecal stasis lasts.

In order to prove the truth of this reasoning I have made a number of experiments, of which the following is typical. Take a healthy dog and make sure that the animal has a normal digestion. To do this let him swallow a colored powder (carbon or carmine) and ascertain that his feces do not contain any mucus, coagulated or not. Some particles of hyaline mucus are always found in the normal stool. Make, then, a permanent fistula on a line with the ileum as near as possible to the caecum laterally, which opening will not interrupt the descent of the feces and will allow at any time the taking out of the intestinal contents. After the recovery

of the dog his digestion is again examined, and his feces are analyzed in order to ascertain whether the intestines functionate normally. Through the fistula a portion of the intestinal contents is taken out at different times, when numerous particles of hyaline mucus, more or less colored by the bile, will be found. These particles are later absorbed in the large intestines, as they are no longer found in the stool. We then cause in this normal animal an abundant oversecretion of mucus, to see what will be the result. To accomplish this the dog was made to swallow through a catheter a solution of silver nitrate. As soon as this solution comes in contact with the mucous membrane it produces a great overproduction of the mucus. After five or ten minutes

FIG. 1.

this secretion is to be neutralized by a physiological salt solution. The mass taken from the fistula will now show large mucous masses, the quantity of which is much greater than that found in the normal mucus. If the treatment has been too violent the animal will be attacked by a profuse diarrhea and discharge the mucus. When these phenomena of reaction are missing, that is to say, when the passage is not considerably accelerated, the examination of the feces will not reveal more mucus than under normal conditions.

As a result of this experiment we can suppose that it is possible that there will be an oversecretion of mucus when the passage is not accelerated, such as is the case in mucomembranous colitis.

It may, therefore, be concluded that all pathogenic theories, based solely on oversecretion of the mucus, are at least incomplete. They do not give a satis-

<sup>1</sup>The fistula is to be made with the help of the small incision at Umbone, fastened to show outside of the wound, and held with a special buttonhole according to the method described by Treves.

factory explanation of the excretion, and do not explain coagulation.

c. Coagulation.—Why does mucus coagulate? Mathieu has advanced a very ingenious theory. He says that after exudation from the mucus layer in the intestine a portion of the liquid may be reabsorbed and the consistency of the mucus increase in proportion to the reabsorption. This is the theory of desiccation. But what is the reason for the elective reabsorption of the watery portion of the mucus? Why does dehydration take place instead of total reabsorption, as is the case in normal condition and was noted in our experiments? It must be surmised that the mucus undergoes a change of physical condition or of chemical constitution, which makes it unfit for absorption, however large the quantity of

has observed it and we also have proved its action by numerous experiments. "The presence of bile always delays coagulation and prevents it absolutely when present in large enough proportion. This action takes place *in vitro* and can be proved in all evacuations."

We have thus ascertained two new facts of great importance: 1, The coagulative power of a testinal extracts; and, 2, the anticoagulative action of the bile. Summarizing shortly the results of our labor, we can deduce the following conclusions from our experiments: 1, The mucus in grains of hyalin changes into yellow from the bile, collected from an ileac fistula, is entirely absorbable, and is proof against coagulative action. This fact can now be easily understood when we take into consideration the anticoagulative action of the bile. 2. Oversecretion does not necessitate excretion if the digestive passage is not very much shortened. It is necessary and sufficient that the mucus should become coagulated in order to be also excreted. Oversecretion and desiccation are therefore secondary phenomena. It is unnecessary to insist upon the importance of the anticoagulative action of the bile.

Thus the symptoms indicating mucomembranous evacuation may now be well understood. It is the consequence of a coagulation of mucus which can no longer be reabsorbed. Whatever be the duration of the digestive passage it will be necessarily rejected.

Let us now look at the second symptom: Delayed digestive passage of constipation, which, as well as mucomembranous evacuation, is the primary symptom, so much so indeed that it was rightly said that to make it

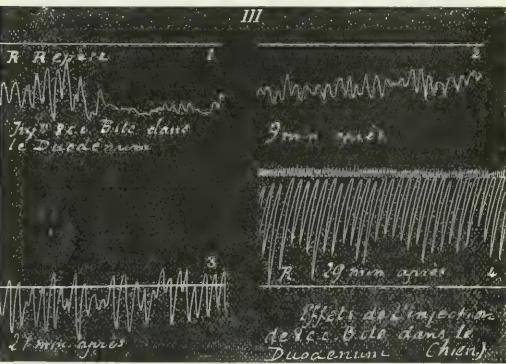

FIG. 2.

excretive mucus may be, and in whatever intestinal segment the absorption takes place. Under this condition the mechanism of desiccation would appear.

Experiments have corroborated this hypothesis. Professor Roger<sup>2</sup> has shown the coagulability of certain intestinal extracts when in contact with mucus. This phenomenon can be reproduced *in vitro*. Roger attributes this action to a special ferment which he calls *muclnase*. I have myself produced this action of coagulation *in vitro*, without differing in opinion as to the specific nature of this action.<sup>3</sup> I too have found this specific action in the feces of patients evidently affected with enterocolitis, and in such patients only. Consequently it is both necessary and sufficient for the mucus to have been submitted to this action, so that it may be excreted; desiccation takes place only to increase its consistency, and oversecretion to increase the quantity. These latter two are only secondary phenomena, coagulation is the primary.

But there exists in the intestine a liquid which prevents coagulation. This is the bile. Dr. Roger

disappear would mean to cure the mucomembranous enterocolitis.

I certainly do not take into consideration in this definition any delay of evacuation due to some obstacle situated more or less higher up, such as a tumor in the intestine or a pressure by some other organ. I consider exclusively what may be called essential constipation.

*Second Part.*—Constipation. Whether we accept the opinion of some authors that constipation is due to atony; or the opinion of others that it is due to a more or less local spasm; or the opinion of a great number of authors that it is caused by the combined action of spasm and atony in different segments, the question remains the same, because atony and spasm are only signs of troubled intestinal activity, and do not at all explain the cause of trouble in the action of peristalsis. Why is this peristalsis deranged? What are the causes of spasm and atony? This is the question in its true light.

I have often asked myself whether there does not exist a correlation between the causes of coagulation and those of constipation, or, to be more definite, whether the anticoagulative function of the bile is not accompanied by some motor excitation upon the intestinal fibre. If this hypothesis should prove correct constipation and coagulation of the mucus would be phenomena of the same origin, that is, of a diminished biliary secretion, coagulation needing a second factor always, the presence of a coagulatory stimulant.

<sup>2</sup> Comptes rendus de l'Académie de Médecine, Paris, 1899, No. 433.

<sup>3</sup> H. Netter, "Sur la coagulation du mucus intestinal," *Gazette des hôpitaux* No. 70, June 20, 1907.

Let us now examine upon what basis this hypothesis might be founded. "Thus, for instance, constipation would usually occur when the bile did not flow into the intestine. On the other hand (Leyden and Schülein), digestion of biliary salts would produce diarrhoea and vomiting."

These arguments, says Dastre, cannot be admitted as having been proved. Eckard tries to solve the question by experiments following the lead of Fubini and Luzzati.<sup>6</sup> The results were rather divergent and did not prove much. The technique, according to Eckard, left much to be desired. As I also desired to solve this question I made some researches with Mr. Hallion; first, whether the bile exerts some motor exciting action upon the intestinal fibres in general; and, second, what variation our experiments would show when made in different segments when bile would be introduced into a vein or would be brought into direct contact with the intestinal mucus membrane.

I shall not report the technique of our experiments; it may be sufficient to say that an ampulla was introduced into the intestine, which transmitted the different pressure to a registering drum of Marey by the help of a water manometer. The details are described somewhere else.<sup>8</sup> I shall only say here that our researches were made in different segments of the intestinal canal, the conclusions of which we shall publish later. I shall reproduce here only a part of the tracing, which has already been published. Fig. 1 represents the evolution of intestinal peristalsis in the duodenum during forty-seven minutes with two interruptions, the first of one minute, the second of seven minutes. It can be seen that before the injection the intestinal contractions took place moderately often around a middle tonus which was rather constant; this was especially the case during a long period before the tracing was done, about three hours. An injection was slowly made into the saphena, first three c.c. and later seven c.c. of bile. At first a marked degree of the peristalsis and a slacking of the middle tonus was observed. Soon after this the contractions were seen to become much longer. At the same time the tonus was much increased. A horizontal line shows the result.

Fig. 2 shows the same motor effect produced by direct injection of bile into the duodenum. Fig. 3 shows the local effects of the bile injection into the rectum. The number of respirations is noted, and also the time in seconds. During the first three hours of this experiment no rectal contraction nor defecation is noted. Then 10 c.c. of bile are injected into the rectum. After four minutes repeated defecation was noted during the following eight minutes. The experiment was stopped for ten minutes, but during this period, which is partly represented in the left side in Fig. 3, a single contraction (b, c) of the anal region was sufficient to produce immediately a contraction of the perineum altogether similar to the one that accompanied the move-

ments of defecation represented in the tracing on the right side of the figure.

These facts may well be compared with the results of numerous experiments which I have made on man. When 50 c.c. of bile was introduced through a catheter into the rectum about 15 centimetres above the anus one will always obtain defecation in cases of the most stubborn constipation. After five minutes the patient usually feels the imperious necessity to go to stool, sometimes resulting in a colicky passage, which stops directly after the expulsion of the faeces. It is therefore evident that bile has a motory effect upon the rectum, which can be and is utilized in therapeutics.

Following are the conclusions which we have drawn from the experiment:

1. The bile when in contact with the mucus of the intestine exercises locally a motory influence upon the small intestine as well as in the rectum.
2. Introduced into the blood circulation, it gives the same result.

3. The later action seems at least partly the result of an exaggeration of bile secretion, due to the chologological influence of the injected bile.

The experiments, therefore, prove absolutely an indefinite action of the bile in the intestine, of its exciting motor influence. Any decrease, therefore, of biliary secretion will effectually diminish the value of intestinal peristalsis—that is, it will lengthen the duration of the digestive passage, or, in other words, bring about constipation, which will last until this secretion is reestablished. One will understand now why from the beginning we observe that all of the causes taken into consideration to explain the aetiology of enterocolitis point to one common origin, action upon the liver. Intoxication, troubled digestion, etc., lead to overworking of the liver, resulting into a tiring out of the organ, which means

Fig. 3

a decrease of biliary secretion, thus producing enterocolitis.

Therefore, if I summarize the experiments reported in this article I find that: To be constipated means to have an insufficient biliary secretion, the result of innumerable causes. Suffering from enterocolitis means constipation and evacuation of coagulated masses—that is, to have an increased secretion of bile. Consequently constipation and enterocolitis have the same origin. They are both varieties of the same affection, two states of the same affection, enterocolitis differing from constipation only by the action of a second factor, coagulation power. The mechanism of intestinal and constipation, therefore, seems to be well established.

As soon as the liver is overworked, an amount of whatever cause (and this will happen, especially in patients who suffer from overstimulation of

2954, 2955, 2956, 2957, 2958, 2959, 2960, 2961, 2962, 2963, 2964, 2965, 2966, 2967, 2968, 2969, 2970, 2971, 2972, 2973, 2974, 2975, 2976, 2977, 2978, 2979, 2980, 2981, 2982, 2983, 2984, 2985, 2986, 2987, 2988, 2989, 2990, 2991, 2992, 2993, 2994, 2995, 2996, 2997, 2998, 2999, 3000, 3001, 3002, 3003, 3004, 3005, 3006, 3007, 3008, 3009, 3010, 3011, 3012, 3013, 3014, 3015, 3016, 3017, 3018, 3019, 3020, 3021, 3022, 3023, 3024, 3025, 3026, 3027, 3028, 3029, 3030, 3031, 3032, 3033, 3034, 3035, 3036, 3037, 3038, 3039, 3040, 3041, 3042, 3043, 3044, 3045, 3046, 3047, 3048, 3049, 3050, 3051, 3052, 3053, 3054, 3055, 3056, 3057, 3058, 3059, 3060, 3061, 3062, 3063, 3064, 3065, 3066, 3067, 3068, 3069, 3070, 3071, 3072, 3073, 3074, 3075, 3076, 3077, 3078, 3079, 3080, 3081, 3082, 3083, 3084, 3085, 3086, 3087, 3088, 3089, 3090, 3091, 3092, 3093, 3094, 3095, 3096, 3097, 3098, 3099, 3100, 3101, 3102, 3103, 3104, 3105, 3106, 3107, 3108, 3109, 3110, 3111, 3112, 3113, 3114, 3115, 3116, 3117, 3118, 3119, 3120, 3121, 3122, 3123, 3124, 3125, 3126, 3127, 3128, 3129, 3130, 3131, 3132, 3133, 3134, 3135, 3136, 3137, 3138, 3139, 3140, 3141, 3142, 3143, 3144, 3145, 3146, 3147, 3148, 3149, 3150, 3151, 3152, 3153, 3154, 3155, 3156, 3157, 3158, 3159, 3160, 3161, 3162, 3163, 3164, 3165, 3166, 3167, 3168, 3169, 3170, 3171, 3172, 3173, 3174, 3175, 3176, 3177, 3178, 3179, 3180, 3181, 3182, 3183, 3184, 3185, 3186, 3187, 3188, 3189, 3190, 3191, 3192, 3193, 3194, 3195, 3196, 3197, 3198, 3199, 3200, 3201, 3202, 3203, 3204, 3205, 3206, 3207, 3208, 3209, 3210, 3211, 3212, 3213, 3214, 3215, 3216, 3217, 3218, 3219, 3220, 3221, 3222, 3223, 3224, 3225, 3226, 3227, 3228, 3229, 3230, 3231, 3232, 3233, 3234, 3235, 3236, 3237, 3238, 3239, 3240, 3241, 3242, 3243, 3244, 3245, 3246, 3247, 3248, 3249, 3250, 3251, 3252, 3253, 3254, 3255, 3256, 3257, 3258, 3259, 3260, 3261, 3262, 3263, 3264, 3265, 3266, 3267, 3268, 3269, 3270, 3271, 3272, 3273, 3274, 3275, 3276, 3277, 3278, 3279, 3280, 3281, 3282, 3283, 3284, 3285, 3286, 3287, 3288, 3289, 3290, 3291, 3292, 3293, 3294, 3295, 3296, 3297, 3298, 3299, 3300, 3301, 3302, 3303, 3304, 3305, 3306, 3307, 3308, 3309, 3310, 3311, 3312, 3313, 3314, 3315, 3316, 3317, 3318, 3319, 3320, 3321, 3322, 3323, 3324, 3325, 3326, 3327, 3328, 3329, 3330, 3331, 3332, 3333, 3334, 3335, 3336, 3337, 3338, 3339, 3340, 3341, 3342, 3343, 3344, 3345, 3346, 3347, 3348, 3349, 3350, 3351, 3352, 3353, 3354, 3355, 3356, 3357, 3358, 3359, 3360, 3361, 3362, 3363, 3364, 3365, 3366, 3367, 3368, 3369, 3370, 3371, 3372, 3373, 3374, 3375, 3376, 3377, 3378, 3379, 3380, 3381, 3382, 3383, 3384, 3385, 3386, 3387, 3388, 3389, 3390, 3391, 3392, 3393, 3394, 3395, 3396, 3397, 3398, 3399, 3400, 3401, 3402, 3403, 3404, 3405, 3406, 3407, 3408, 3409, 3410, 3411, 3412, 3413, 3414, 3415, 3416, 3417, 3418, 3419, 3420, 3421, 3422, 3423, 3424, 3425, 3426, 3427, 3428, 3429, 3430, 3431, 3432, 3433, 3434, 3435, 3436, 3437, 3438, 3439, 3440, 3441, 3442, 3443, 3444, 3445, 3446, 3447, 3448, 3449, 3450, 3451, 3452, 3453, 3454, 3455, 3456, 3457, 3458, 3459, 3460, 3461, 3462, 3463, 3464, 3465, 3466, 3467, 3468, 3469, 3470, 3471, 3472, 3473, 3474, 3475, 3476, 3477, 3478, 3479, 3480, 3481, 3482, 3483, 3484, 3485, 3486, 3487, 3488, 3489, 3490, 3491, 3492, 3493, 3494, 3495, 3496, 3497, 3498, 3499, 3500, 3501, 3502, 3503, 3504, 3505, 3506, 3507, 3508, 3509, 3510, 3511, 3512, 3513, 3514, 3515, 3516, 3517, 3518, 3519, 3520, 3521, 3522, 3523, 3524, 3525, 3526, 3527, 3528, 3529, 3530, 3531, 3532, 3533, 3534, 3535, 3536, 3537, 3538, 3539, 3540, 3541, 3542, 3543, 3544, 3545, 3546, 3547, 3548, 3549, 3550, 3551, 3552, 3553, 3554, 3555, 3556, 3557, 3558, 3559, 3560, 3561, 3562, 3563, 3564, 3565, 3566, 3567, 3568, 3569, 3570, 3571, 3572, 3573, 3574, 3575, 3576, 3577, 3578, 3579, 3580, 3581, 3582, 3583, 3584, 3585, 3586, 3587, 3588, 3589, 3590, 3591, 3592, 3593, 3594, 3595, 3596, 3597, 3598, 3599, 3600, 3601, 3602, 3603, 3604, 3605, 3606, 3607, 3608, 3609, 3610, 3611, 3612, 3613, 3614, 3615, 3616, 3617, 3618,

arthritis, in patients who have a sedentary occupation), biliary secretion will decrease, and, according to the cases, result either in enterocolitis or in constipation. When this becomes later chronic mucomembranous evacuation will take place, possibly complicated by all kinds of infections, either in the liver (angeiocholitis, cholecystitis, gallstones, or in the intestines, appendicitis, etc.).

In certain cases mucomembranous evacuation produces the emission of intestinal sand. In the *Biochemical Journal*, II, 9, August 20, 1907, Owen T. Williams shows that this sand contains eighty per cent. of acids saturated with fat (stearitin and palmitin), which form, so to say, the nucleus of these sand grains. This phenomenon only becomes possible by diminished absorption of the fatty substance—that is, by decreased biliary function. This is an addition to the proof which we have furnished in the course of this paper.

Finally the treatment which I have instituted and described in detail elsewhere is based on these experiments, and has given me very good results. A very strict diet is to be prescribed after a trial meal, which makes it possible to recognize the food which is most easily digested, and to discover pancreatic oversecretion, which is often associated with enteritis. The treatment consists in prescribing a biliary extract, to be administered as described, partly through the mouth and partly through the rectum. My technique has enabled me to obtain the best results where other treatments have failed.

With these facts before us I think I have a right to formulate the following theory:

1. The false membrane is the agent which increases coagulative power and diminishes biliary secretion, which permits its beneficial function.

2. Mucomembranous enterocolitis is the result of biliary oversecretion.

## A PLEA FOR SYSTEMATIC USE OF BRONCHOSCOPY IN OUR ROUTINE WORK.

### *With Description of a Modified Bronchoscope.*

BY WOLFF FREUDENTHAL, M. D.,  
New York.

At the time when Killian published his method for the direct examination of the trachea and bronchi, it was mainly with the idea of utilizing it for the removal of foreign bodies from these parts. This method has since been extensively employed and with excellent results, but as we are aware, it still is in its infancy. The introduction of the bronchoscope is not only difficult to learn and difficult to execute, but it is troublesome to the patient. Often a good deal of pain is caused and general anæsthesia has to be resorted to in quite a number of instances. No one doubts the justifiability for our taking all this trouble, since in cases of foreign bodies there is a question of life and death, and any procedure is permissible that will save the patient.

But it appears to me that a method that enables us to inspect these parts should be utilized for other purposes as well and in a more systematic manner.

Parenthetically it may be added that bronchoscopy, as might be expected, has been employed for the diagnosis of tumors and aneurysms in or near the trachea and bronchi, but of course these cases are of rare occurrence. The field for investigations is much larger. Some work has been done already in other directions, as for example by A. Loewy and the late H. von Schroetter in their studies of the circulation of the blood through the bronchoscope. But that is a mere beginning, and it would seem that a great deal more can and will be accomplished. First of all idiopathic diseases of the lower air passages should be studied *in vivo*, their direct treatment attempted, etc. At first sight it would appear that these affections are rare. But if we look for them systematically, most likely the same will happen as with the laryngoscope; many a hitherto obscure affection will be elucidated. Hence systematic examinations of the trachea and bronchi should be made just as is customary in the larynx. But how?

With the instrumentarium at our disposal this is well nigh impossible. Take for example the "separable or slide speculum" of Chevalier Jackson. It is a strong instrument which enables the operator to get a firm grasp and control over his patient, and Jackson is justified in feeling proud of it. But for routine work any such contrivance is out of the question. Besides there are other drawbacks which render bronchoscopy difficult and sometimes impossible, as a too fleshy tongue, large teeth, narrowness of the fauces, inability to sufficiently separate the jaws, a very low position of the larynx, etc. Last but not least, I agree with von Schroetter, that the dexterity and technical ability of the operator himself play the most important rôle.

It is with the aim of overcoming at least some of these difficulties that the "jointed bronchoscope" has been devised by the writer.

From a historical point of view it must be mentioned that flexible instruments for examination of the œsophagus were devised by Kelling, of Dresden. Kelling's ingenious œsophagoscope was introduced, bent, and afterward straightened by a scissor like mechanism. Kolliker modified this by using an elastic tube provided with a stylet (mandrin). After the tube was in position he removed the stylet and introduced in place of it a metallic tube. These instruments for the œsophagus have nothing in common with my bronchoscope, but are mentioned here for the sake of completeness.

When beginning my experiments in bronchoscopy, it occurred to me that the bronchoscope might be introduced in the same way as any laryngeal instrument, viz., with the aid of the laryngeal mirror. As that could not be done with a straight instrument, one capable of being bent had to be devised. The flexible œsophagoscopes did not seem suitable for this purpose, and a *jointed* instrument was contrived. This bronchoscope consists of two parts of about equal length, the distal portion (b, c) being narrower in order to fit in the other. The joint (c) is exactly as shown in the cut, leaving an opening in the upper portion when the tube is bent. The patient is thereby enabled to breathe through it even when it is at a right angle. There is no opening at c when the tube is straightened.

It soon was noticed that the distal end (b, c) was too long to be of much service, and consequently it was gradually shortened so that its length in the latest instrument is two and one half inches.

Afterward another question came up, viz., that of proper illumination. Different sources of light have been utilized. The first instruments for auto-scopy were provided with Casper's electroscope, as used by him for cystoscopy. Rosenheim, of Berlin, utilized it for œsophagoscopy, and Kirstein for bronchoscopy. Better, however, was the headlight of Kirstein or Killian. H. von Schroetter used a miniature osmium lamp and endeavored to place the light where it is wanted, viz., at the distal end. He availed himself of the well known phenomenon of the conduction of light in a glass rod. If a light is placed at one end of a glass rod it will shine with the same intensity at the other end, this being due to its conduction through the rod. Instead of the latter von Schroetter used a glass tube which was introduced into the bronchus. The inner surface of this tube is blackened so that one looking into it sees only the illuminated distant end.

I have not tried von Schroetter's method, but have employed Kirstein's and Killian's headlight. I

Freudenthal's modified bronchoscope.

must confess, however, that there are difficulties attending the use of these headlights which I could not overcome. First it is not always easy to focus the lamp correctly. Secondly and of more importance is the fact that even when the light is adjusted properly the distal end is not satisfactorily illuminated. For that reason the light carrier first used by Max Einhorn for the œsophagoscope and then adopted by Chevalier Jackson for the bronchoscope was added. After the bronchoscope was *in situ*, the light carrier was inserted. But this prolonged the whole procedure and was therefore discarded as unsatisfactory for most cases. The next step was the construction of a flexible light carrier instead of the rigid one. This was accomplished in such manner that the flexible part of the light carrier, viz., the cable (d) fitted into the section (c) so that it was easily bent during manipulations of the instrument, while at the same time it was sufficiently rigid to be readily inserted.

The mode of procedure is as follows: The tube is grasped, not by the handle, but by the longer end (a, c) just like a penholder. The patient pulls down his tongue. With the aid of a laryngeal mirror, the light of the bronchoscope at b furnishing the illumination, the instrument is introduced like in any other intralaryngeal procedure. As soon as it is in the larynx, the tube is straightened (see dotted lines in figure), and we then proceed as usual.

One of the important points in bronchoscopy is the local anesthesia. With a spray of cocaine

(four per cent.) the epiglottis, base of the tongue, and the whole introtitus of the larynx are anesthetized. After this a swab moistened in a ten to twenty per cent. solution of cocaine is applied to the lower parts. In order to do away with that disagreeable feeling of thickness that is so objectionable to many patients after the use of cocaine I have lately employed alipin (twenty to thirty per cent.) in a number of cases. The result was that the patients did not experience the same degree of unpleasant sensation in the throat.

While some colleagues, who have watched the introduction of the tube, were surprised at the ease with which it was done, two objections were raised. Firstly it was suggested that while straightening the tube the mucous membrane might be caught at the upper end of the joint (c). Thus far this has never happened, and I believe we may eliminate its probability. The second objection was that the distal end (b, c) might become bent during its introduction. If that should happen it would be noticed immediately, because the light would go out. By drawing the tube up a short distance, or turning the handle to one side or the other, this has been always corrected in a few seconds. But should it

happen in an exceptional case that one is unsuccessful in straightening the tube and thus restoring the light, the flexible light carrier should be withdrawn and the rigid one inserted.

The writer has done considerable work with this improved bronchoscope, especially in cases of tuberculosis pulmonum, but is not yet prepared to publish the details of his experience.

It is my belief that this modification of Killian's instrument will render bronchoscopy much easier than before. As proof of how much its application is facilitated it may be noted that we were able to introduce the jointed bronchoscope in a case of bilateral recurrent paralysis with the vocal cords in the so called cadaveric position.

Whatever may be the experience of others, let us at least try to extend the scope of the bronchoscope to other lines of investigation.

1003 MADISON AVENUE.

## MALNUTRITION.

By MORRIS KORSNET, M. D.,  
Baltimore, Md.,

Editor, *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*,  
CHICAGO, ILL.

The Burlingham report, compiled by a board of educators who investigated the health of the school children in many of our large cities, states that out of six hundred thousand school children in the city of New York, four hundred and sixty-five thousand eight hundred were physically defective. Of the number two hundred and thirty thousand eight hundred suffered from defective breathing, one hundred and eighty-seven thousand from enlarged glands, and forty-eight thousand from malnutrition. The proportion is as follows: Enlarged glands, 48.8 per

cent.; bad teeth, 72.4 per cent.; malnutrition, 12 per cent.; eye defects, 14.4 per cent.; nose troubles, 27.7 per cent.; and throat troubles, 29.9 per cent. Were this percentage maintained throughout the United States, since rural districts exhibit physical defects similar to those of the urban, it would mean that there are one million four hundred and forty thousand ill nourished children, five million six hundred and fifteen thousand with enlarged glands, and six million nine hundred and twenty-five thousand with defective breathing—a total of thirteen million nine hundred and eighty thousand children whose physical defects not only retard their mental development but handicap them in the struggle for existence with those whom the chance of birth favored with vigorous constitutions.

As they stand, these figures are sufficiently alarming; but reduced to a scientific analysis they expose a state of physical deterioration that is simply appalling. Unfortunately the report, like all reports emanating from charitable bureaus, terrifies but does not teach. In such reports the symptoms of the social disease are so skillfully classified that the disease is not only obscured, but the symptoms themselves become of interest only to physicians or criminologists. To the masses, a statistical display of this kind merely awakens the suspicion that the children's eyes are weak as a result of excessive study, or their teeth bad because of overindulgence in sweets. And the children are taken to an oculist to have their eyes tested, or to a dentist to have their teeth repaired, while the underlying causative condition is entirely overlooked.

The laity and many members of the medical profession fail to grasp the simple fact that the eyes, ears, nose, lungs—in short, all organs of the body—act primarily for the benefit of the entire body and only secondarily do they function for their individual development. Hence, an injury or disease of any organ must disturb the entire system, and, conversely, an injury or disease of the system affects the individual organs, particularly the delicate organs of special sense which require a large and varied amount of nutriment for their maintenance and growth.

The basis of life is nutrition. All living things, from the simple unicellular amoeba to the complex specialized organism—man—require nutriment in some form or other. Food the tissue builder, air the energy supplier, and sunshine that warms and freshens germinating life into full bloom, are the nutritive trio without which all life on this planet would cease. A disturbance in the quantity or quality of any of these elements means a disturbance of life. So long as the human being receives the proper proportion of these substances he remains healthy despite the millions of disease producing bacteria which continually surround him. But let this nutritive equilibrium be deranged and immediately some part of the body weakens; the part, its resistance lessened, becomes fertile soil for the implantation of germ colonies, and thus nutrition is further impaired by the diseases generated.

The Burlington report arranges the physical defects into diseases of the nose, throat, eyes, teeth, and glands, but attributes to malnutrition only twelve per cent. of the cases. The actual fact is that malnutri-

tion is the direct cause and the various diseases specified are only symptoms of the poorly nourished condition, just as fever, coated tongue, nose bleed, vomiting, and purging are symptoms of typhoid fever. Malnutrition, the gaunt handmaid of poverty, insidiously invades the body of its victim and, breaking down all protective barriers, leaves the body defenseless to the ravages of disease.

Malnutrition does not begin the moment the child starts, without any breakfast, to "creep like a snail unwillingly to school." Its beginnings are at conception, when the cells of an overworked and underfed male and female unite; in utero, when the mother, beside the drain of gestation, must perform the arduous labor of a housewife or factory hand; and finally, after birth, when it must feed upon breast milk lacking nutritive qualities or cows' milk obtained from tuberculous cattle or adulterated and laden with poisonous preservatives.

The symptoms of malnutrition are loss of flesh, delayed dentition, backward muscular development, nervous excitability, poor circulation, and anemia. Enlargement of the lymphatic glands is common, especially of the neck; the inflammation of the glands may start from a slight cold, but the glands remain enlarged for months after the cold has subsided. The children are seriously affected, often fatally, by all acute diseases, and especially susceptible to acute diseases of the stomach and intestines, the so called summer complaint. A striking characteristic is their vulnerability; they "take" everything. The nose, pharynx, and bronchi are easily attacked by acute catarrhal inflammations which invariably become chronic. Thus malnutrition manifests itself locally and generally, and by a process of tissue starvation leaves the system an easy prey to most pathological changes known to medicine.

An extreme and frequently fatal degree of malnutrition, seen in the dispensaries of large cities and especially common in institutions for infants, is termed marasmus. Literally, it means infantile atrophy. The child simply wastes away, death resulting from some acute disease.

Marasmus is essentially a disease of the poor. While seen in premature children and in the illegitimate offspring of young girls, the great majority of cases are due to two things—the food and the surroundings. The disease is rarely, if ever, found in the country. Here the infant, though poorly fed and neglected, receives an abundant supply of fresh air and sunshine, and, as a rule, does well. In the congested districts of the city, if the infant has an adequate amount of good breast milk, it continues to thrive in spite of its pernicious surroundings. But woe to the infant brought up in a tenement and artificially fed! It is doomed to an infancy of an intolerable suffering, a childhood of chronic torment, and a vitiated maturity that will reproduce a race of physical, mental, and moral defectives.

Overcrowding of infants in institutions is another important cause of marasmus. In his experience in four institutions, Dr. L. Emmett Holt, professor of children's diseases in the College of Physicians and Surgeons (Columbia University, New York), finds that more than half the deaths under one year were directly or indirectly from this cause. The determining factor in the fatal result is marasmus, but

the cause of death is usually reported under some other name. Though fed by thoroughly scientific methods, infants, who on admission were chubby faced and lusty, lose bit by bit, until at the end of three or four months become mere skeletons, incurable cases of marasmus, perishing of some mildly acute disease such as indigestion or bronchitis, the intrinsic cause nevertheless being marasmus. With the very best ventilation, one thousand cubic feet of air to each human being is absolutely essential to health. In most institutions for infants only five hundred cubic feet are allowed, and, in many instances, where too many children are placed in one ward, they receive considerably less.

The diseases of children that medicine distinguishes as due to faulty nutrition are scorbutis and rachitis. An understanding of the symptomatology of these diseases, particularly rachitis, will throw some light on the origin of many derangements afflicting the school child and youth, and demonstrate the absolute necessity of proper food and surroundings as the foundation stone for healthy growth and physical and mental training.

Scorbutis or scurvy is an acute disease due to some continued dietary error. It is characterized by spongy, bleeding gums, swellings and blood eruptions about the joints, hæmorrhages from the nose and other mucous membranes, extreme sensitiveness to pain, protrusion of the eyeball, pseudoparalysis of the lower limbs, and marked general deterioration, with intense anæmia.

The age is an important index in this disease. More than four fifths of the cases occur between the sixth and fifteenth months and one half between the seventh and tenth months, showing clearly that it is a disease of infancy. The disease occasionally manifests itself in children in evident good health and excellent surroundings.

The diet is the direct cause of this disease. Many theories have been advanced for the causation of scurvy by the diet, but so far nothing definite is known, except that there is something lacking in the food which is required for the nutrition of the body. One fact that stands out clearly is that breast milk and cows' milk give the smallest percentage of cases. The following report of the American Pædiatric Society's collective investigation of infantile scurvy in 1898, embracing 379 cases, reported by 138 observers, proves conclusively the kind of food that is at fault:

Previous Food: Breast milk in twelve cases; raw cows' milk in five cases; pasteurized milk in twenty cases; condensed milk in sixty cases; sterilized milk in 107 cases; and proprietary infant foods in 214 cases. This establishes condensed milk, sterilized milk, and the proprietary infant foods as the chief causative factors of scurvy. The disproportion between pasteurized milk heated at 157° F. (for thirty minutes) and sterilized milk (usually heated to 212° F. for one hour) is interesting. The large number of cases due to sterilized milk confirms the conclusion that the heating alone was the cause, since prompt recovery followed the discontinuance of heating. It also demonstrates the necessity of properly testing and preparing cows' milk. Scorbutic symptoms disappear rapidly when condensed milk and the proprietary infant foods are discon-

tinued and good breast milk or properly modified cows' milk resumed. The addition of fresh fruit juices aids recovery very materially.

Rachitis or rickets is a chronic disease of malnutrition. The quaint description of this disease by the celebrated English chaplain, Thomas Fuller (1608-1661), holds to this day: "There is a disease of infants called the rickets, wherein the head waxeth too great and the legs and lower parts wane too little." The most prominent manifestation of rickets is extensive, and usually permanent, changes in the bony structure of the body. The head is abnormally large as compared with the face, the skin is pale and thin, and the child has an old and wise look far beyond its years. The bones are soft in spots and the sutures remain open. The ribs at about an inch from the breastbone present beaded elevations known as the "rachitic rosary." At this point, also, owing to a falling in of the ribs, vertical and transverse grooves of the chest are formed. The breastbone is frequently depressed, producing the "funnel chest" deformity, or it may be elevated, giving the "pigeon breast" effect. It is easy to understand how such deformities, impairing the vigor and vitality of the respiratory organs by compressing them and restricting their movements, pave the way for all acute pulmonary diseases, and that most dreaded of all chronic diseases—tuberculosis. The ankle and knee joints, by a process of softening in one spot and overgrowth in another, present the "bow legs" and "knock knees" so familiar to all. The spine is sometimes curved inward or to the side, and the pelvic diameter shortened, rendering labor, in later life, extremely difficult and dangerous. Dentition is delayed and difficult, and accompanied by frequent attacks of indigestion. These attacks, attended by imperfect absorption, produce a condition known as autointoxication (literally, selfpoisoning), wherein the system is exposed to all manner of infections from within and without. The abdomen, protuberant from the persistent gas accumulation, is stretched tight as a drumhead, making the child "pot bellied." An early symptom is profuse sweating at night, especially of the head. As a result, colds are easily contracted, and these infants almost always suffer from some form of nasal or bronchial catarrh. Rachitic infants are highly susceptible to enlargement of the lymphatic glands of the neck, enlarged tonsils, and adenoid growths of the pharynx.

The coexistence of scurvy and rickets in the same patient, as established by the society's investigation, adds further proof to their dependence on deficient nutrition. Of the 340 cases of scurvy, in which this condition was noted, symptoms of rickets were present in 152 cases, or 45 per cent. In seventy-two children the symptoms were reported as slight; in sixty-four marked; and in sixteen not specified. In fifty of the rachitic patients it was recorded that the rickets preceded the appearance of scurvy.

Rickets can be traced to two great causes, diet and surroundings. Children reared on the proprietary infant foods and sweetened condensed milk generally suffer from rickets. These preparations contain an excess of sugars and starches, but are low in fats. This deficiency in fats causes the rickety condition. Rickets have been produced ex-

perimentally in animals by withholding mother's milk and feeding them on meats, vegetables, or starches.

The influence of surroundings is proved by the fact that rickets occurs principally in children who live in crowded tenements. A few weeks' change to the open country, where they can get plenty of good food, fresh air, and sunshine works marvels in these children.

The prolonged use of the proprietary infant foods has so often resulted in scurvy and rickets that there can be no doubt that they were the active cause. Dr. Holt's experience, as indeed that of most intelligent physicians, forces the conclusion that the infant foods, as frequently used by the laity and even the medical profession, are capable of doing and have done much positive harm. They should only be used like drugs in diseased conditions when temporary stimulation of the body is required.

When we consider that the practice of maternal nursing is rapidly diminishing—among the wealthy because of anxiety to preserve their forms and the fear of losing a moment in the quest for pleasure, and among the poor because the mill and factory call the mother to assist in maintaining a semblance of the cherished tradition "home," and that these mothers, rich and poor, find in the proprietary infant foods cheap and convenient substitutes for nursing or cows' milk—we can readily realize the vast amount of physical deterioration that follows in the wake of such helpless, misguided, and vicious mal-feeding.

The extreme cases of malnutrition are rarely met in private practice because of inability to pay for treatment which must necessarily extend over many months and even years. It is in the dispensaries and hospitals of the slum districts of large cities that the most pitiable cases are seen. Some of them, in all their squalor and rags, present such pathetic pictures of abject poverty as to arrest the attention of physicians and nurses accustomed to such sights and bored by the helpless sameness of them.

In the Gouverneur Hospital Dispensary for Children's Diseases of New York, the records show an average of fifteen hundred cases a month. Through the kindness of Dr. Tunick, in charge of this department, I was permitted during the summer of 1907 to examine three hundred children and to closely question two hundred mothers. The examination into the social conditions and maternal habits of the mothers developed the following facts: Ninety-six lived in three room flats, sixty-two in four room flats, and the remaining forty-two in five room flats. These flats were in tenements in the vicinity of the hospital, and fearfully lacking in light, ventilation, and bath tubs. With few exceptions, the women admitted a lodger or two, some keeping as high as three and four. One woman with a severely rachitic child stated that she lived in five rooms, had seven children, and kept six lodgers. "What can one do," she naively asked, "when the wages of one's husband are only six dollars a week, hardly enough to pay for the food of the family?"

About one half of the women nursed their children, while the other half were fed on "baby food" and "zwieback." Many of the children over one

year old, and some that had been weaned, were permitted to eat at the table with the adults, and one pale, anæmic little infant of six months was brought in vigorously sucking a fig!

Fully ninety per cent. of these children displayed unmistakable evidences of malnutrition, and, as Dr. Tunick informed me, this percentage was maintained throughout the year. A diagnosis in these cases is hardly necessary. For purposes of convenience, the cases are arranged according to the seasons. In the winter their sufferings are recorded as "colds" and in the summer as "indigestion." These exhibit all degrees of acuteness and intensity, but the possibility of a permanent cure, without a radical change in the food and surroundings, is so remote that they lose even scientific interest.

Besides derangements of the respiratory and digestive tract, the majority of the children were afflicted with sore eyes, nasal and pharyngeal growths, large tonsils, and swollen glands. It was a common occurrence to meet the same children in the departments for diseases of the eye, ear, nose, and throat. For instance, Dr. Grushlaw, in charge of the nose, throat, and ear department, stated that more than seventy per cent. of his cases are sent to him through Dr. Tunick's department, and most of the new cases must be sent there for general treatment.

And so the vicious circle is maintained. A faulty supply of the life giving elements, food, air, and sunshine, produces general diseases, with localized symptoms in the eye, ear, nose, throat, teeth, and glands, and a proper investigation into these special manifestations leads one back to the primal cause—malnutrition.

As an illustration of the lack of maternal care among the children of the poor and of the "home preserving" tendencies of the present social system, Dr. Tunick instanced the case of an old woman who visits the dispensary regularly every two weeks with eight to twelve children, claiming them as grandchildren, great-grandchildren, or some other relatives. The doctor is certain she is paid five or ten cents a day to see that the children are taken care of and receive medical treatment while the mothers are out at work. He recalls seeing her at other dispensaries in the interim of her visit to the Gouverneur Hospital.

A physically defective child means a mentally defective child. A child with a half starved weak body is in no condition to perform the arduous tasks of the modern classroom. Physically and mentally defective children mean physically and mentally defective men and women, which in turn means that in one or two generations we will have a nation of physical, mental, and moral degenerates. It is high time that we bestir ourselves in behalf of the children if we wish to save our race from the fate of the Græco-Roman civilizations.

What is the remedy? Unfortunately, medicine has no answer, for it is as blind to the correction of social conditions as are the other professions. Medicine, like law, which punishes the criminal while crime hatching conditions remain untouched, bends all its knowledge and skill to the suppression of diseases and their symptoms, while social conditions breeding disease are completely overlooked.

It is curious to note that the National Association

for the Improvement of the Condition of the Poor, under whose auspices the Burlingham Commission carried on its investigations, has nothing better to offer the physically defective children than a "tooth-brush and a cake of soap for every child." Which means that if the negligent poor will only keep their children's teeth clean and their hands and faces spotless to delight the æsthetic tastes of certain charitably disposed ladies and gentlemen, their empty stomachs could be entirely forgiven them. In short, charitable bureaus and associations for "improving" the poor do everything to soften the shocking features of poverty, but absolutely nothing to remove it entirely.

Modern hypnotism asserts that the hunger and thirst of subjects can be satisfied, during deep hypnosis, by the suggestion of food and drink. If charitable bureaus and associations were aware of this fact, the perplexing problem of "improving the poor" would be speedily solved. The establishment of a class of hypnotism for the suggestion of food and drink to the underfed school children would make the children happy and contented, and relieve kind hearted philanthropists and their agencies of heavy responsibilities.

Conditions make the man, and only secondarily does man react on his conditions. Social conditions to-day deny to the laboring classes an opportunity to procure for themselves and their children proper food and surroundings, with the result that malnutrition swiftly enters to disable and kill. Personal hygiene and compulsory medical treatment may correct certain physical defects, but not until faulty social conditions are removed will the basic cause of these defects be eliminated. A change in social conditions will not only assure to the working classes an abundance of good food, fresh air, and sunshine, thus weeding out the ills of malnutrition, but make of the physician a public officer working for the prevention of disease for the general good in place of an individual business man treating disease as a means of private gain. Then, and only then, will the school child, properly fed, clothed, and housed, be in a fit physical and mental condition to absorb what it is taught.

In the meantime, the vast number of poorly nourished and physically defective children call for immediate ameliorative measures. The city should provide a wholesome free lunch for all school children, and, in cases that require it, shoes and clothing. It should establish numerous public playgrounds and baths with trained gymnastic and hygienic teachers in charge. A system of compulsory calisthenics in the schools, together with periodical medical examinations for the reparation of physical defects, should be instituted. Large tracts of open country outside of the city limits should be set aside as camping grounds for the children during the summer. The city should organize milk depots where properly modified cows' milk could be procured at small cost. It should also establish airy and commodious nurseries, with skilled attendants in charge, where women compelled to work can leave their children. The health board physicians should visit the tenements regularly and instruct mothers in the nursing and feeding of infants and have full powers to remedy unsanitary conditions.

In short, everything should be done, so far as possible, to obviate the evil effects of malnutrition, but with the understanding that malnutrition itself is but an effect, and can only be completely and permanently eradicated when its fundamental cause—our present social and economic system—is completely transformed.

## THE ROLE OF THE SPHENOPALATINE (OR MECKEL'S) GANGLION IN NASAL HEADACHES.\*

BY GREENFIELD SLUDER, M. D.,  
St. Louis, Mo.,

Clinical Professor, Diseases of the Ear, Nose and Throat,  
Department, Washington University.

Occasionally it has been my lot to be consulted by patients who were in every way healthy and normal, but who suffered much of the time from headache which did not follow any of the known rules. It was irregular as to the time of its appearance, and irregular as to the part of the head involved. Sometimes it was referred to behind the eyes, sometimes to the upper jaw in front, and sometimes to the hard or soft palate. Occasionally the nose was said to ache in the back, or the teeth were described as sore, or the pain was referred to the temple and to the occiput or neck. This headache appeared most irregularly, but was seldom absent for more than a short time. It sometimes would become severe and behave as a migraine. Sometimes an indefinite sense of stiffness was described. These symptoms appeared from day to day, alternating one with the other, or associated two or three together. On one occasion I had them all described at once.

Within the past six months I have seen some high grade inflammatory troubles in the posterior ethmoidal and sphenoidal sinuses, which have subsided and healed, usually within a week or two, but have left the train of symptoms, as described, in their wake, and these have continued on more or less indefinitely. This exceedingly irregular train of symptoms cannot be explained on a basis of inflammatory troubles in the accessory sinuses.

They seemed to me neuralgic and to have been excited by the forerunning inflammatory process in the nose. The coal tar products give transitory relief.

The position of the sphenopalatine (Meckel's) ganglion in such close relation to the accessory sinuses and the external wall of the nose suggested the possibility of its involvement secondary to inflammations in these parts. Furthermore, the distribution of the nerve processes of this ganglion corresponds closely with many of the regions in which pain is referred by these patients. Sobotta<sup>1</sup> describes the sphenopalatine ganglion as follows (Vol. III, p. 1000):

The sphenopalatine ganglion is a rounded, triangular body lying in the prepared forerunning inflammatory process in the nose. It is connected with the trunk of the maxillary nerve by the long and short branches.

Read before the International Congress of the Otolaryngological Society, St. Louis, Mo., May 15, 1907.

sphenopalatine nerves, which form its sensory root. In addition to this main root it receives a second, the nerve of the pterygoid canal (Vidian nerve), which passes through the corresponding canal of the pterygoid process of the sphenoid and really consists of two nerves usually very closely united in their course through the canal, one of which is the motor, the other the sympathetic root of the ganglion. The motor part of the nerve is the greater superficial petrosal nerve, a branch of the geniculate ganglion (of the facial nerve). It courses through the groove named after it in the anterior surface of the pyramid of the temporal bone, then through the sphenopetrosal fissure (or foramen lacerum), and then it crosses the internal carotid artery and enters the posterior aperture of the pterygoid canal. The second component of the nerve is the sympathetic root of the ganglion and is known as the deep petrosal nerve. It arises from the internal carotid plexus and passes from the foramen lacerum to the pterygoid canal, in which it unites with the preceding to form the nerve of the pterygoid canal.

The branches of the sphenopalatine ganglion are:

1. Small orbital rami to the orbit, which enter through the inferior orbital fissure and supply the smooth musculature of the orbit and the periorbita. A longer branch unites with the posterior ethmoidal nerve and helps in the supply of the mucous membrane and of the sphenoidal sinus.

2. To the nasal cavity: (a) The posterior superior lateral nasal rami enter through the sphenopalatine foramen and pass to the mucous membrane of the superior nasal meatus and of the superior and middle nasal conchæ and also to that of the sphenoidal sinus and the posterior ethmoidal cells. A few delicate fibres also pass posteriorly to the uppermost portion of the pharyngonasal cavity. (b) The posterior superior medial nasal rami also enter through the sphenopalatine foramen and ramify in the mucous membrane of the posterior part of the nasal septum. A longer branch known as the nasopalatine nerve passes obliquely across the nasal septum from above and behind, downward and anteriorly, to the incisive canal, into which it sends some slender filaments which anastomose with the

corresponding nerve of the other side and also with the terminals of the anterior palatine and superior alveolar nerves, forming with them a small plexus through which it takes part in the innervation of the pulp of the upper incisors. (c) The posterior nasal rami, which supply the posterior part of the lateral wall of the nose, do not enter through the sphenopalatine foramen but course with the palatine nerves for a short distance in the pterygopalatine canal. They leave this canal a short distance from its length through a lateral opening, and ramify in the middle and especially in the inferior nasal conchæ and in the middle and inferior meatus, and also in the mucous membrane of the maxillary sinus. Its branches also anastomose with the superior dental plexus.

3. To the palate. The branches from the sphenopalatine ganglion going to the palate pass along with the descending palatine artery through the pterygopalatine canal. In this they divide into several branches, invested by a common sheath, these making their exit from the canal through the palatine foramina. These branches are: (a) The anterior palatine nerve, the strongest of the set, which passes through the anterior palatine foramen and ramifies with the greater palatine artery in the mucous membrane of the hard palate, reaching the incisive canal, where it anastomoses with the nasopalatine nerve. (b) The middle palatine nerve is much weaker than the preceding and passes through one of the minor palatine foramina; it ramifies in the mucous membrane above the palatine tonsil and in the velum of the palate. (c) The posterior palatine nerve also passes through one of the small palatine foramina, and in the palatine velum ramifies not only in the mucous membrane but also in the levator veli palatini and in the uvula. It, therefore, contains motor fibres and nerves, which are supposed to enter the nerves by the great superficial petrosal, originating, that is to say, from the facial.

The connection of the sphenopalatine ganglion with the seventh nerve, Sobotta described as follows:

At the first bend of the facial canal below the hiatus a small triangular ganglion, the geniculate ganglion, occurs in the course of the nerve, formed by the intermediate or 1<sup>st</sup> nerve of Wislizenus, which from this point onward courses

with the facial nerve. Since the facial nerve, as well as the canal, makes a rectangular bend at the ganglion, this point is termed the (external) geniculum of the facial nerve. From the ganglion arises the greater superficial petrosal nerve which passes to the sphenopalatine ganglion as described above. Probably this nerve contains fibres passing not only from the facial to the maxillary nerve, but also reversely, and thus carries sensory fibres from the trigeminal to (the peripheral part of) the facial; it forms, therefore, a mutual anastomosis. Also arising from the geniculate ganglion there is an anastomotic ramus to the tympanic plexus.

I have found the position of the sphenopalatine ganglion to vary, sometimes being deeper and sometimes superficial in relation to the external wall of the nose; sometimes in close relation to the apex of the maxillary sinus; sometimes close to the sphenoidal sinus; sometimes close to the post ethmoidal labyrinth; sometimes higher, sometimes lower.

I then began the experiment of anesthetizing the ganglion, or at least attempting it, by an applicator tipped with a very small amount of cotton, such as would be moistened by one drop of a twenty per cent. cocaine solution, and placing it just over the ganglion, that is, as a rule, just posterior to the posterior tip of the middle turbinate. I found that for some patients it relieved all the symptoms completely and invariably. For some others it relieved all the symptoms except pain in the neck; for some it failed completely or helped very little. Where it succeeded I have thought the ganglion was close to the external wall of the nose, and where it failed it probably laid deeper. The relief would last for from fifteen minutes to an hour; occasionally it would abort the attack.

Of the ten cases I have observed none were of sufficient severity to warrant operative interference. Application of silver two per cent. or formaldehyde one half per cent. to that area of the nose either cured or helped the pain.

From the relation of the apex of the maxillary sinus to the sphenopalatine ganglion the inflammatory process might spread from this sinus to the ganglion; but I have not so far observed this.

#### MIDDLE EAR DEAFNESS.

BY W. SOHIER BRYANT, A. M., M. D.,  
New York.

Our grandfathers classified ear diseases in two categories—those that got well without treatment and those that resisted all treatment. In our day there are very few cases of chronic middle ear deafness that cannot be improved, and acute middle ear deafness is very amenable to treatment. The exceptions are the cases of malformation of the middle ear, the cases of advanced stapes fixation, and those of extremely advanced otosclerosis.

The amount of the possible improvement in hearing is in inverse ratio to the pathological changes. Chronic deafness from past or present suppuration of the middle ear can, without exception, be helped by treatment. The amount of help depends upon the power of the patient to make repair and to substitute parts which have been lost. Deafness following middle ear catarrh is more resistant.

When we realize that about ninety-eight per cent. of the cases of chronic deafness are due in whole or

part to middle ear disease, then we appreciate the great frequency of chronic middle ear deafness. About eighty-four per cent. of the cases of chronic middle ear deafness are due to middle ear diseases alone, while fourteen per cent. are due to middle ear diseases combined with diseases of the inner ear. Of the cases of chronic middle ear deafness, about eighty-three per cent. are due to chronic middle ear catarrh alone; fifteen per cent. are due to present or past suppurative of the middle ear; one per cent. is due to stapes fixation, and less than one per cent. to congenital malformation of the middle ear. The fifteen cases which are the result of suppurative are often complicated by chronic middle ear catarrh. We see, therefore, that ninety-eight per cent. of chronic cases of middle ear deafness are due in whole or in part to "chronic middle ear catarrh."

Chronic middle ear catarrh makes about sixty-nine per cent. of all chronic deafness, while middle ear suppurative causes about thirteen per cent. of chronic deafness. The causes of chronic middle ear catarrh arise in the nasopharynx and affect the middle ear by interfering with the Eustachian tube. The aim of treatment is first to restore the functions of the Eustachian tube; and, second, to correct the defects of the middle ear. By treatment of nasopharynx, prophylaxis of these defects is easily assured.

The causes of stapes fixation are trophic disturbances. Not only must these disturbances be checked, but their recurrence must be prevented.

The chief difference between the etiology of middle ear suppurative and chronic middle ear catarrh is pyogenic bacterial infection. Suppurative occurs almost never independent of nasopharyngeal disease. Prophylaxis of chronic middle ear deafness due to suppurative is secured by preventing purulent inflammation through care of the nasopharynx. But if suppurative has already begun the hearing is preserved by immediately stopping the suppurative and by treating the nasopharynx appropriately. If any suppurative should exist in chronic middle ear deafness it must be immediately arrested. If perforations of the membrane exist they must be closed by the growth of cicatrices. In order to compensate for the important parts of the sound conducting mechanism which may have been lost, it is necessary to adjust mechanical appliances. Adhesions of important parts must be loosened.

Besides showing the second stage of stapes fixation (Case X), the following cases also show the three conditions caused by chronic middle ear suppurative, together with their nine methods of treatment (Cases I to IX). The thirteen conditions of chronic middle ear catarrh and their treatment are also shown (Cases XI to XXIV).

CASE I.—No. 12076. A man, aged thirty-four. Chronic middle ear suppurative with impaired hearing for six years. Perforation of Siegmund's membrane. Politzer's accumulator heard less than three feet. Nine weeks later, after cleansing treatment and cessation of suppurative, accumulator heard at thirty-five feet. Improvement has persisted to the present time, covering a period of three years.

CASE II.—No. 12076. A man, aged twenty-seven. Chronic middle ear suppurative for four years; small perforation of membrana tympani and considerable loss of hearing. Politzer's accumulator heard at three feet. Three months later, after cleansing treatment and ces-

sation of suppurative, accumulator heard at thirty feet. Improvement has continued over three years.

CASE III.—No. 12124. A woman, aged fifty-three. Suffered from effects of chronic middle ear suppurative; large, dry posterior perforation of drum membrane. Politzer's accumulator heard at twelve inches. The other ear worthless. The perforation was caused to cicatrize over by aid of paper dressings. Six weeks later, Politzer's accumulator heard at eight feet. Improvement has continued.

CASE IV.—No. 13000. A woman, aged twenty, who had been rejected in a civil service examination. Effects of chronic middle ear suppurative. Adhesion of malleus handle to promontory. Perforation of drum head had already closed. Watch heard at five inches. The other ear worthless. Two and a half months later, after forcible catheterization and relaxation of the bands of adhesion, watch could be heard at seventeen inches, and applicant passed a successful civil service examination. Improvement retained.

CASE V.—No. 13070. A doctor, aged forty-five. Long standing suppurative and large perforation in membrana tympani. Politzer's accumulator heard at ten inches. One week later, after cleansing treatment and cessation of suppurative, the perforation was closed with paper dressings; accumulator heard at twelve feet.

CASE VI.—No. 14207. A woman, aged twenty-four. Suppurative since childhood; total loss of drum membrane and the three ossicles. Watch heard at one inch. Other ear of little use. One week later, after cleansing treatment and cessation of suppurative, tympanic ballast was adjusted, watch heard at thirty-six inches. Improvement continues over three years.

CASE VII.—No. 12077. A woman, aged twenty-seven. Suppurative since childhood; loss of drum head and cicatricial attachment of malleus to promontory; early impairment of hearing. Politzer's accumulator heard at twelve inches in right ear. Left ear absolutely deaf. Cleansing treatment and cessation of suppurative. Politzer's accumulator heard at four inches. Tympanic ballast then adjusted, accumulator heard at eight feet. Ballast caused return of suppurative. A mustard anastomosis was performed in order to allow the use of the tympanic ballast. After convalescence Politzer's accumulator heard at thirteen inches. Ballast adjusted, accumulator then heard at nine feet. Watch heard at two inches. Condition remained the same. Functional tests without tympanic ballast: Tone perception, high limit, 76,800 single vibrations (Edelmann-Galton); low limit fork 1,024 single vibrations. Bone conduction 0. With tympanic ballast in place: Tone perception, high limit, 30,400 single vibrations; low limit fork, 128 single vibrations. Bone conduction, fork 512 single vibrations heard on mastoid. A time also existed for a time, fork 2,048 double vibrations not heard by air conduction while other forks were heard.

CASE VIII.—No. 14278. A man, aged sixty-five. Chronic middle ear suppurative of many years' duration with poor hearing. Watch heard at four inches. My modified radical mastoid operation was performed. Cessation of suppurative and watch heard at ten inches.

CASE IX.—No. 13048. A woman, aged twenty-four. Suppurative since infancy; loss of all tympanic contents; tympanic caries. Watch heard at contact. Radical (Schwartz-Stacke) mastoid operation performed. Convalescence complete in three weeks without skin grafts. Cessation of suppurative, and watch heard at ten inches. The patient has retained the improvement now for four years.

CASE X.—No. 14226. A man, aged sixty-seven. Stapes fixation in the second stage. Deafness commenced eight years ago; hearing had been very bad for three years; this condition was possibly aggravated by a common cold. Hearing variable. Drum membrane whitish and opaque. Position normal, and light reflex normal; malleus movable. Politzer's accumulator heard in right ear at nine inches, left ear at three inches. Loud conversation heard on right ear at six inches, left ear at thirty-two inches. Watch heard in either ear. Bone conduction, much diminished. Fork, 128 single vibrations not heard by air conduction by bone. Fork, 512 single vibrations not heard by air. High notes well heard. Tympanic membrane greatly thickened and irregularity of basal middle of the middle ear. Six months later Politzer's accumulator heard in right ear at twenty feet.

watch at twenty inches; in left ear, acoumeter at four and one half feet, watch not heard at all. Improvement has continued now for a period of four years.

CASE XI.—No. 13083. A man, aged forty-seven; had noted deficiency in hearing for eighteen years. Drum heads good color, fair contour and position, light reflex very small. Nares partially occluded by hypertrophies and irregularities. Fosse of Rosenmüller partially closed by adhesions. Tubal mouths slightly obstructed by thickened mucosa. Watch heard in right ear at fifteen inches; in left ear, at four inches. Astringents and irritants to nasopharynx. Three years later, watch heard at forty-eight inches in left ear and eighty-four inches in right ear. Improvement maintained.

CASE XII.—No. 14528. A man prematurely old at forty-seven. First noted impaired hearing thirty-four years ago; losing ground ever since in spite of much treatment. Has not heard watch in right ear for twenty-one years, and in left, twenty-five years. Flat, opaque, retracted drum membranes; no light reflex, rigid. Nares hypertrophic; inflation by Politzer's method or catheterization impossible. By air conduction, right ear, low tone limit fork 1,024 single vibrations; high tone limit fork 2,048 single vibrations. Left ear, low limit, 512 single vibrations; high limit 4,096 single vibrations. Bone conduction decreased. Right ear, low tone limit by bone conduction, 1,024 single vibrations; high limit fork, 8,102 single vibrations. Left ear, low limit by bone, fork, 1,024 single vibrations; high limit, 8,192 single vibrations. Very loud voice heard at one foot in right ear; left ear, at eight inches. Bougies, local astringents, and stimulation. Portions of lower turbinates removed. Eight months later, low tone limit in left ear, fork, 256 single vibrations; right ear, fork, 268 single vibrations; high tone limit 40,000 single vibrations in both ears. Politzer's acoumeter heard in right ear at fifteen inches; in left ear at twenty-seven inches. Watch heard light contact on both ears. Loud conversation heard in right ear at five and a half feet; left ear at four feet. Eustachian tubes patulous; appearance of drum membrane much improved in every respect; good light reflex, color, position, and surface, still somewhat opaque.

CASE XIII.—No. 14177. A woman, thirty-eight years old. Had undergone much injudicious treatment. Eustachian tubes used to be closed, now cannot close. Diminished hearing began fifteen years ago. Membrana tympani thin, flaccid, readily movable. Politzer's acoumeter heard at twenty inches in right ear. Treated by rest, stimulation, and collodion splints. After six months, Politzer's acoumeter heard at four and a half feet; watch, at two and one fourth inches. Improved function of Eustachian tube.

CASE XIV.—A man, aged forty-three. For several years the patient's hearing had been impaired; drum head retracted; good color, contour, and reflex. Did not move on inflation. Watch heard at one and a half inches; after inflation heard at twenty-four inches. Treatment, inflation and pharyngeal astringents; one month later, watch heard at eighteen feet.

CASE XV.—No. 14096. A man, aged twenty-seven. Impaired hearing for a number of years; much deafness in family. Drum membranes slightly congested along malleus handle and periphery, and depressed, small light reflexes, inflation difficult. Nasal engorgement. Left ear, watch heard at five inches; right ear, watch heard at nine inches. Bone conduction slightly prolonged. Low notes well heard. High limit, left ear, 39,000 single vibrations (Edelmann-Galton). Right ear, 44,000 single vibrations. Treated by inflation, removal of part of lower turbinates, and astringents. Three days later, watch heard at twelve feet; left ear, at ten inches. Improvement maintained.

CASE XVI.—No. 13012. A man, aged sixty-seven. Some difficulty in hearing for a number of years. Membrane very thick and white, with thinner areas. Large light reflexes. Inflation slow. Politzer's acoumeter heard in right ear at twenty-five inches; in left ear, at seven inches. High tone limit, left ear, 29,000 single vibrations (Edelmann-Galton). Right ear, 20,000 single vibrations. Right ear, low tone limit, 102 single vibrations. Treatment, astringent to nasopharynx and aural stimulation; two weeks later, Politzer's acoumeter heard in right ear at five feet; left ear, at fourteen feet.

CASE XVII.—No. 14649. A man, aged fifty-eight. Extremely deaf for two years; hearing difficult many years. Thick, flat, contracted drum heads; no light reflexes; Eustachian tubes fairly patulous. Could hear nothing by

on the cheek. Heard very loud noise close to his ear. Treated by nasal counter irritation and tympanic stimulation. After several treatments, acoumeter heard in right ear at two inches; left ear, at five inches. High tone limit, right ear, 24,000 single vibrations (Edelmann-Galton); left ear, 22,000 single vibrations. Low limit, left ear, fork, 250 single vibrations; right ear, fork, 1,090 single vibrations. Eight months later, ordinary voice heard by air at four feet. Low tone limit fork, 128 single vibrations, by air in both ears.

CASE XVIII.—No. 14160. A woman, aged fifty. Hearing had been defective twenty-five years. Partial nasal obstruction. Drum head depressed, very thin, transparent, and lax. Inflation not perfect; watch not heard. Right ear, the better ear. Politzer's acoumeter heard at five feet. Low tone limit, 256 single vibrations. Treated by nasal astringents, removal of part of lower turbinates, and aural stimulation. Fifteen months later, watch heard at thirty-six inches. Low tone limit, fork, 113 single vibrations. High limit, 43,000 single vibrations (Edelmann-Galton).

CASE XIX.—No. 14128. A man, aged forty-five. Impaired hearing many years. Right ear absolutely deaf; left ear, relaxed drum membrane. Patulous Eustachian tubes. Politzer's acoumeter heard at seven inches. Treatment, paper splints and collodion. Six months later, left ear heard watch at one and a half inches; acoumeter at twelve feet. Resiliency of drum membrane restored. Improvement maintained.

CASE XX.—No. 12099. A woman, aged thirty-nine. Had long noted trouble in hearing. Right ear, the best ear. A large part of the drum membrane calcified. The tube not perfectly patulous. Politzer's acoumeter heard at two inches. Treated by inflation, astringent to nasopharynx, and tympanic stimulation. One month later, right ear, watch heard at eighteen inches. Mobility and elasticity of the sound conducting mechanism improved.

CASE XXI.—No. 14179. A man, aged forty-one. Had been a little deaf for a number of years. Left ear showed a somewhat depressed gray membrane with irregularly depressed surface after inflation, indicating bands of adhesions running to the inner tympanic wall. No history or evidence of suppuration. Tympanic inflation difficult. Acoumeter heard at three inches. Treatment, inflation and tubal astringents. Four months later, Politzer's acoumeter heard at four feet in left ear. Adhesions appear to be entirely relaxed.

CASE XXII.—No. 14177. A woman, aged thirty-eight. Noted impairment in hearing fifteen years ago. Previously tubal stricture, much injudicious treatment, now permanently open tubes and abnormally movable left drum membrane and malleus, less of elasticity of membrane and extreme laxity of malleal ligaments. Bone conduction much increased, low notes deficient, high notes well heard. Left ear, acoumeter heard at twenty-five inches. Treatment by collodion splints, rest, and irritation of pharyngeal mouth of tube. Five months later, watch heard in left ear at four and three fourths inches. Politzer's acoumeter heard at ten feet.

CASE XXIII.—No. 14861. A woman, aged thirty-five. Some difficulty in hearing for at least two years. Tympanic membrane fairly normal in appearance. Malleus immovable. Right ear, watch heard at seventeen inches; left ear, at three inches. High tone limit, left ear, 40,000 single vibrations (Edelmann-Galton); right ear, 48,000 single vibrations. Gellé positive, low limit left ear fork, 134 single vibrations; right ear, 174 single vibrations. Bone conduction, normal duration. Treated by tympanic and tubal stimulation. Six weeks later, left ear, watch heard at nine inches; right ear, at twenty-one inches. High tone limit, right ear, 85,000 single vibrations; left ear, 92,000 single vibrations. Low limit, 128 single vibrations both ears.

CASE XXIV.—A boy, aged thirteen. Patient had always had slightly defective hearing. Watch heard at twenty inches in both ears. Mastoiditis and operation treated with my modified blood clot dressing. After convalescence from the operation, the ear operated on for mastoiditis heard the watch at twelve feet.

*Summary.* We have seen that all forms of middle ear deafness except the congenital cases are amenable to treatment, and that the amount of improvement justifies the effort expended.

## A NEW METHOD OF ANATOMY STUDY.

BY FREDERIC GRIFFITH, M. D.,  
Rome, Italy.

*Introduction.*

Of all the manifest difficulties encountered by students of medicine at the very outset of professional school life the topic of anatomy looms most stupendously before the mind's eye contemplating the stage of its coming mental activities. Continued thought of the beginner upon the matter serves but to strengthen preconceived notion—accentuated by wellnigh universally expressed opinion of all other past and present medical tyros—namely, that the subject of human anatomy is at once the most intricate, hardest to fix in mind, and easiest forgotten of any branch of medical knowledge.

One desirous to discover the reasons for the perplexities overshadowing the way of him who would become a skilled anatomist will not seek far before becoming impressed by the very same thought which, however undiscerned, acted so overpoweringly upon the student himself. In a word, the real cause for the hardness of anatomy lies in the very essence of anatomy itself as commonly presented. Ambiguity in this statement will be cleared if the reader will momentarily allow his mind to dwell upon the abstract aspect of the subject under discussion. Consider the term anatomy and what is presented to consciousness. Is it not the body in its entirety? This presentation of the whole crowding the brain becomes the primal source of confusion when localized disassociation of the subject is attempted. Entering from the surface, the deeper one delves the more complicated the structures, until the inquirer becomes lost in a maze of contra relationships of muscles, bones, vessels, nerves, and visceral organs.

That which serves to so confound the casual glance acts similarly in the student's mind, and by reason of the incompleteness of his study causes anatomical facts to remain but lightly fixed in memory.

The monuments of Cheops have remained the marvel and bewilderment of the centuries since the secret of their construction slept after two or three generations from the builders. Lately has come one who suggests that the pyramids are cement. Proved to be so, the mystery of those imperishable piles is solved and the tradition of the "hundred thousand straining backs" tugging quarried blocks of a size not worked in our time becomes mere figure of language. To reduce the anatomical stumbling block and to render its grasp facile for the learner by means eminently practical is the purpose of the present writing.

To study a house without the aid of the architect's plans, even though one may have the privilege of tearing the building down, serves but to mystify and is likely to leave the intrepid investigator exercising the extreme prerogative standing finally amid a wreck of thought and disjointed bricks. Markedly similar is the result after the average dissector has approached a human body in search of its secret conformation.

Based upon the thought that a reconstructive process logically should follow close after the analyzing dissecting knife if the student is to gain proper

grasp of subject anatomy, the system to be presently described is projected. Every sincere anatomy teacher, mindful of dissecting room shortcomings, has thought, if indeed he has not voiced, keen sorrow at the constant waste of material caused by thoughtless, untrained students. Too often parts are merely flensed hastily, as footpads scour their victim's pockets.

Admittedly but little is ever gained from the dissection of a first part. To present anatomy from the very beginning, recognized as being made up of local and distinctive elements, the several factors entering into the construction being as easy of retention when once properly presented before the mind as is the reassembling of a bony skeleton once set up, is what is strived for by the method of synthetic development described in this article. To be able to replace the component materials entering into a construction carries the individual possessed of such power a long ways towards an understanding of it, but to be enabled to create the parts in some similitude, however crudely, first, if built upon a sound foundation, is to accomplish far more.

By the aid of some plastic material and an assembled bony skeleton the anatomy student will have at hand the means of fixing facts upon his memory after every part dissected in a manner inconceivably valuable. By ordinary dissecting methods one gains sight of existent relationships. If the common practice, however, is followed by a synthetic process the student gains thereby a strengthened brain impression. Whereas, in the former he saw merely the picture, by the latter means he duplicates the imprint, for now he not only sees the bare fact, but is forced to consider every concept by reason of the manual effort in the reproduction.

*Equipment.*

The materials necessary for the development of the synthetic method of anatomy study are:

(1) Provision for a skeleton of average size, preferably that secured from the body of a muscular male adult. Thus is provided a sure control and foundation for all the subsequent production, the well marked bony prominences serving as positive guides for the building up of the soft parts. Such a skeleton may be readily secured, selected, cleansed, properly assembled, and wired, from the dissecting room supply of material in the early fall at the beginning of college work; or it may be obtained from dealers in anatomical and surgical supplies at a cost of thirty to sixty dollars. One such skeleton may be adequate to serve the practical needs of a group of four or even six students. Where there are larger classes a number of the skeletons should be provided.

While assured that if synthetic demonstrations were instituted as regular supplemental procedures at the close of anatomical courses much would be gained, greatest good is obtainable when the student himself prepares his own specimens. The actual work at modeling of the anatomical duplicate directly after completion of the dissection serves to fasten the facts as nothing else can do.

(2) The modeling material may consist of any one of the following. A recognized plastic substance well fitted for the intended work having a foundation of wax, being in general use by sculptors, is

known under the trade name of plastilina. It is placed first upon the list of desirable shaping matter for the reason that it is most practical and least troublesome of all to use. The substance comes in three consistencies, of which that termed medium or hard will be found most satisfactory for present purposes. Manufactured in several colors, and as it is muscle relationships which will be particularly studied and which are of greatest importance in fixing nerve and bloodvessel locations, red should be chosen as being nearest the natural tint. Put up in one pound packages and selling for twenty-five cents apiece; ten cakes will be found amply sufficient for carrying out complete detail work. Ordinary modelling clay costing at the rate of about three cents a pound may be used. This clay has the disadvantage of it being necessary to keep it constantly wetted to prevent crumbling. Fifteen or twenty pounds weight of clay may be provided, as it is somewhat heavier in a given quantity than in the case of the first mentioned material. The clay is best kept in a stone crock or closed enamel vessel. When obtained the mass should be broken up by the fingers into small pieces of about the size of walnuts and spread in layers in the receptacle. Each layer to be well sprinkled with water. Finally the whole should be covered in with a dampened cloth to prevent evaporation of the water. Very lately has appeared a modified clayey substance termed by the inventor, a Norwegian sculptor, "classical clay," from its partaking of the nature of modelling material used by ancient Greek and Roman artists. This clay may be readily employed as a medium for carrying out synthetic anatomy study, its cost being but about twice that of ordinary modelling material. Classical clay has distinct advantages in that the finished work does not require to be kept wet during the intervals of study; also from the fact that additions may be added without in any way disturbing the original construction.

The implements required for the working of the plastic materials are few. Two or three of the broad and narrow ended wooden modelling tools, selling for small cost at art material shops, or the student may provide a spatula like tool whittled from a piece of broom handle, finding it satisfactory for every purpose. Chief reliance is to be placed upon the student's own fingers for the carrying out of the work, as it is the act of modelling the parts which serves unconsciously to fix the anatomical fact being studied at the time firmly in mind.

### *The Body Surfaces.*

The value of synthetic study of surface markings becomes apparent when it is recalled that physical anatomy depends upon the landmarks of the subcutaneous bony prominences, muscular and facial elevation and depression, for its basis. Not alone is the surgeon dependent, but also the physician, upon the fixed body points, in the determination of the extent and character of surgical injury or internal disease. The ease with which accurate knowledge of what goes to make up surface prominences and contiguous structures is evident by a mere cursory examination of any of the standard anatomy textbooks. A wealth of pictorial description shows the bones of the skeleton carefully marked with origin and insertion of all the muscles thus acting as ready

guides, but which hitherto without the connecting link of plastic material and transfer to the bony skeleton has been neglected.

### *The Head.*

After completing the dissection of the head or during the course of the work, with the skeleton head set up beside that of the subject, duplication may be commenced.

Muscles of the Face and Cranium.—Beginning with the temporal muscle, for convenience, its origin and insertion are to be examined in the subject. Reproduction upon the skeleton head may then be carried out, making frequent comparisons. Cutting off a piece of the modelling material in bulk similar to the temporal muscle to be copied, the lump is to be kneaded and moulded into a somewhat elongated fan shape. By compressing the expanded edge to the temporal fossa and ridges, external angular process of the frontal bone to the mastoid portion of the temporal behind, curved lines of the frontal and parietal bones above to the pterygoid ridge upon the greater wing of the sphenoid below, the origin of the muscle will be traced. The insertion is set upon the inner surface, apex, and anterior border of the coronoid process of the lower jaw, extending almost to the last molar tooth.

The masseter, the remaining muscle entering the temporomaxillary region, is to be copied in a similar manner. This muscle is found to arise from the malar process of the superior maxillary bone and from the anterior two thirds of the lower border of the zygomatic arch; a second, deeper portion of the muscle arising from the posterior third of the lower border and from the whole inner surface of the zygomatic arch. The common insertion being set into the upper half of the ramus and outer surface of the coronoid process of the inferior maxilla. The relations of the parotid gland, fascial, masseteric, temporal, and buccal vessels and nerves may be subsequently indicated.

Pterygomaxillary Region.—The pterygoid muscles, by comparison with the worked out originals in the subject, are duplicated similarly upon the skeleton. Modelling the external pterygoid muscle in the shape of a short and somewhat conical form. The origin is to be indicated by attachment of the mass to the pterygoid ridge upon the greater wing of the phenoid and from the osseous surface lying between it and the base of the pterygoid process; also from the outer surface of the external pterygoid plate. The insertion is set into the anterior depression lying just below the condyle of the lower jaw. The internal pterygoid is formed to arise from the inner surface of the external pterygoid plate and the grooved surface of the tuberosity of the palate bone; also by an extension from the outer surface of the tuberosity of the palate bone and the tuberosity of the superior maxillary bone. The insertion is set into the ramus and angle of the lower jaw, extending as high up as the dental foramen. The vessel and nerve associations are to be carefully considered and indicated.

In like manner the intermaxillary, superior, and inferior maxillary regions are to be plotted. The nasal region being limited upon the skeleton to bone formation, must be prolonged by use of plastic substance to indicate the cartilaginous structure. In

all the work of reproduction the different muscular structures must be actually built up, not merely drawn by indentation upon an adherent mass of plastiline or clay. It is only by the student himself locating and indicating positively the points of origin and insertion of muscular structures that the greatest good is obtainable.

In making a synthetic study of the orbital region special provision by sawing through the frontal bone in such a manner as to open this space sectionally must be made.

The muscular structures entering into the neck are to be duplicated upon the skeleton as found. Beginning with the muscles of the soft palate, the pharynx, anterior vertebral, lateral vertebral, lingual, suprahyoid and infrahyoid, and superficial cervical regions.

#### *The Thorax.*

The thorax, being for the most part made up of more readily worked out structures, owing to their greater size than in the case of the head and neck regions, synthetic study of this portion of the body is most satisfactory. The muscles of the back beginning with the structures forming the fifth muscle layer may perhaps be best built up after a careful reading of the anatomy textbook. So close together are the back muscles that a first dissection is very apt to add confusion rather than clearness to the understanding. This is due to the complicated intermuscular septal supports, whose removal disorganizes the contained muscles.

In the building up process the student may possibly distort somewhat the various layers upon the skeleton model by lack of sufficient care in the proportionment, but he will have at the end clear mental pictures of the lay and action of the structures of the region under consideration.

Upon the thorax the chest wall is to be built up between the model ribs and sternum, beginning with the levatores costarum, intercostales, infracostales, and trianglariis sterni muscles.

#### *The Abdomen.*

The wide expanded structural formation of the abdominal walls likewise causes this portion of the body to be peculiarly adapted for a synthetic study. To prevent collapsing of the set up model muscles employ a bundle of excelsior or crumpled newspapers to take the place of the viscera. Begin the process of reconstruction by first laying down the transversalis and quadratus lumborum muscles; follow with the deep muscles of the abdomen, namely, the psoas parvus and magnus, iliacus. Anteriorly fill in the internal and external oblique, the rectus abdominis, and pyramidalis muscles.

The visceral organs may be added and the perineum built up in conjunction with the development of the thorax and abdomen or separately.

#### *The Upper Extremities.*

Reconstruction of the arm may commence with a reproduction of the pectoralis minor muscle, costocoracoid membrane, pectoralis major and subclavian muscles. Continue by laying down the serratus magnus, subscapularis, supraspinatus, infraspinatus, teres minor, teres major, biceps coracohumeralis, brachialis anticus, deltoid, triceps and subscapularis muscles in the order named. Upon the forearm the deep flexors and extensors, pronator quadratus

supinator longus, pronators, superficial flexors and extensors, abductors, interossei, palmares and dorsales, and the lumbricales muscles.

#### *The Lower Extremities.*

In the synthetic study of the thigh commence with the deep lying muscles of the anterior femoral region, laying down the curreus, subcurreus, vastus externus, vastus internus, rectus femoris, and sartorius muscles, with the tensor vaginæ femoris.

Upon the inner side of the thigh lay the abductor longus, brevis, and magnus muscles, the gracilis and pectineus muscles. About the hip and back of the thigh first set the biceps semitendinosus and semimembranosus muscles; continue with the quadratus femoris, pyramiformis, obturator externus, obturator internus, gemellus inferior, gemellus superior, gluteus minimus, gluteus medius, and finally covering in with the gluteus maximus muscle.

Descending to the region of the lower leg, fill in the anterior tibiofibular region by laying down the extensor longus digitorum, extensor proprius hallucis, peroneus tertius, and tibialis anticus muscle. Posteriorly set the flexor longus hallucis, flexor longus digitorum, popliteus, tibialis posticus muscles; afterwards add the superficial structures of the region, namely, plantaris, soleus, and gastrochemius muscles. Upon the outer side of the leg place the peroneus longus and peroneus brevis muscles.

Continue to the foot, laying down the anterior, internal, and external angular ligaments, indicating the proper relationships of structures passing through or beneath them.

Upon the dorsum of the foot set the extensor, brevis digitorum. In the plantar region set the interossei muscles; flexor brevis hallucis, adductor obliquus hallucis, flexor brevis minimi digiti, adductor transversus hallucis; abductor hallucis, flexor brevis digitorum, abductor minimi digiti.

It must be conceded that a thorough groundwork of the muscles by use of the system indicated in the previous pages founds the whole study of anatomy upon secure basis in the student's mind. Furthermore, elaboration of the synthetic method by laying down nerves, bloodvessels, and organs may be carried out to remotest detail. The synthetic method as well lends itself readily as a means for determining a student's knowledge of anatomy by the examiner.

### Correspondence.

#### LETTER FROM LONDON.

*The Research Defence Society, formed at the Royal College of Surgeons—Anatomists and the Hospitals—Changes to Hospital and Out-patients—The Committee of the Hospitals.*

LONDON, APR. 8, 1908.

A society has been formed called the Research Defence Society, whose objects are to point out to the public, by means of pamphlets, lectures, and debates, the value of experiments on animals to science and medicine. The president is Lord Cromer, and there are nearly a hundred vice-presidents, including some of the most distinguished men in the kingdom. There are, among others, six bishops and four deans. A society formed under

such distinguished patronage can scarcely fail to have great influence, and the public will now have the opportunity of hearing both sides of the question regarding vivisection. Hitherto the antivivisectors have been permitted to work their own will without let or hindrance. The only exception to this general statement was the recent libel action against the Hon. Stephen Coleridge, the leading spirit of the antivivisectors, with the result that he was mulcted in heavy damages. With this exception, the misleading and calumnious statements of the antivivisectors have been ignored by the medical world. It is thought that this passive attitude is a mistake, and that the time has arrived when more active measures are necessary to combat these attacks. With this object the society has been formed, and it will give information to all inquirers who desire to examine the arguments in favor of experiments on animals. It will also publish précis, articles, and leaflets, send speakers to debates if required, and generally spread the knowledge of the truth as regards vivisection.

The honorary secretary is Mr. Stephen Paget, F.R.C.S., to whom the medical world owes a debt of gratitude for his organizing such a powerful and influential society.

Several important letters have appeared in the *Times* and other daily journals on the subject, including some from laymen, testifying to the interest the society has aroused among the educated classes. The society will no doubt be largely joined by members of the medical profession.

The council of the Royal College of Surgeons of England has lately been considering the advisability of admitting women to the examinations for the membership and fellowship of the college. With regard to the membership, there seems little doubt that this privilege will be granted to women. This examination, conjointly with that for the Licentiatehip of the Royal College of Physicians (M.R.C.S., L.R.C.P.), is the standard qualifying examination for English students, and the great majority of medical practitioners in England possess this diploma. As women are now admitted to the examinations of most universities and licensing bodies, there seems no reason why they should not be admitted to the "conjoint" examination. As regards the fellowship, however, opinions are not so unanimous. Though most medical men are prepared to discard their prejudices against the admission of women as physicians, they do not all look with favor on the idea of women practising as surgeons only.

The fellowship being a purely surgical diploma possessed by most of the hospital surgeons, it is thought by some inadvisable to admit women. The opinion of all the members and fellows of the college on these questions has been sought, and they are being asked to vote for or against the admission of women (a) to the membership, (b) to the fellowship. The opinion having been expressed that, if women are admitted to the membership, they could not be legally debarred from entering for the fellowship and having a share in the management, government, and proceedings of the college, the council have taken legal advice on the subject, and find that under their bylaws of incorporation they can

admit women to the membership without admitting them to the fellowship or giving them any right in the management or government of the college.

The result of the ballot will be awaited with interest as affording an idea of the present day opinions of medical practitioners as regards the admission of women to the profession.

The question of the administration of anæsthetics in hospitals is likely to attract considerable attention in the near future. A number of cases of death under anæsthetics have been reported recently, Guy's Hospital having been particularly unfortunate in this respect. At a recent meeting of the Society of Anæsthetists, Dr. F. Hewitt, the leading authority on anæsthetics in the country, expressed the view that most of the fatal cases were preventable and could be avoided by more skill and care on the part of the anæsthetist. Of course, this statement was vigorously contested by most of the other speakers. Dr. Waldo, coroner for the city of London, suggested the appointment of a Royal Commission to inquire into the whole question. So far, the result of the recent discussions has been that extra anæsthetists have been appointed at some of the larger hospitals, two additional ones having been appointed at Guy's Hospital. The great number of anæsthetizations daily in some of the larger hospitals make it absolutely impossible for each one to be conducted by a skilled anæsthetist or even by a qualified man, but as far as possible, when a student gives an anæsthetic, he has previously had some preliminary training and is under skilled supervision. It is worthy of note that most of the recent fatalities have occurred with chloroform or the A. C. E. mixture. It is true that ether is much less used in London than chloroform, but in some of the large provincial hospitals, where ether is principally used, such, for instance, as the General Infirmary at Leeds, fatalities are of very rare occurrence.

The recent proceedings at the Hospitals' Conference have been sharply criticised by general practitioners. One of the motions, submitted by the Hon. Sydney Holland, chairman of the London Hospital, was to the effect that out patients should be asked to pay for food, medicine, and dressings if they could afford it. At the London Hospital the scheme has been in operation for some time. In one year the hospital got £2,000 from a charge of threepence a patient for medicines or dressings. Those patients who did not receive any medicine or dressing did not have to pay, and those who were too poor were also exempt. Mr. Holland considered that the charitable work of a hospital should be restricted to providing for the sick poor that help which they could not possibly afford to provide for themselves, but that a good many could afford a small sum for medicine and dressings. Medical men in general practice object to this scheme on the ground of unfair competition. They say they would lose many patients who could afford to pay a small fee. The resolution is also antagonistic to one of the model principles of the British Medical Association, that "inability to pay for adequate treatment shall be the consideration for the admission of all patients for hospital treatment." There is no doubt that the large hospitals in London, which together treat several hundred thousand patients per annum, already compete

severely with the general practitioner, and the suggested payment by patients will make this competition worse. Doubtless the system of small payments by out patients would increase the funds of the hospitals, but it would be at the expense of the medical practitioner.

The financial state of most of the large hospitals is not at all good; several of them have a whole ward empty owing to lack of funds. But the plight of one of the smaller hospitals at present is still worse. This is the Kensington General Hospital, in Earl's Court. All the inpatients departments have had to be closed, and the out patient work has had to be carried on under great difficulty. The secretary has received several writs from tradespeople for goods supplied to the hospital, and now the climax has been reached, the bailiff's man being in possession, and unless substantial relief is forthcoming, the hospital furniture and effects will be sold. The publicity which has been given to this distressing condition will doubtless call forth a generous response from the wealthy, so that the hospital will be able to continue its charitable work.

### Therapeutical Notes.

**The Treatment of Acute Bronchitis.**—The value of large doses of ammonium carbonate in the treatment of acute bronchitis was, the *St. Louis Medical Review* for April says, believed in by the late Dr. Gustave Schorstein, who recommended as much as fifteen to twenty grains to be prescribed four times daily. If the pulse becomes weak and respiration labored, solution of strychnine hydrochloride should be given hypodermatically. If the symptoms are not very severe, one of the following mixtures may be prescribed:

R Ipecacuanha wine, ..... ℥ vi;  
Solution of ammonium acetate, ..... ʒiiss;  
Syrup of nitrous ether, ..... ℥ xii;  
Syrup of tolu, ..... ʒss;  
Camphor water, ..... ad ʒi.

M. et Sig.: Two tablespoonfuls every four hours.

If the patient is a young adult, and the pulse full and strong, antimonial wine may be substituted for the wine of ipecacuanha in this prescription.

R Ipecacuanha wine, ..... ℥ vi;  
Ammonium carbonate, ..... ʒiiss;  
Syrup of nitrous ether, ..... ℥ xii;  
Syrup of tolu, ..... ʒss;  
Camphor water, ..... ad ʒi.

M. et Sig.: Two tablespoonfuls every four hours.

In some cases Dr. Schorstein recommended the administration of belladonna in combination with potassium iodide as follows:

R Tincture of belladonna, ..... ʒi;  
Potassium iodide, ..... ʒi;  
Ammonium carbonate, ..... gr. xii;  
Potassium carbonate, ..... gr. xv;  
Camphor water, ..... ad ʒi.

M. et Sig.: Two tablespoonfuls three or four times daily.

### Treatment of Sciatica by Perineural Injections.

According to the *Journal of the American Medical Association* for February 20, 1908, A. H. H. of Vienna, is the author of a communication to the

*Wiener medizinische Presse* for November 17, 1907, in which he states that he has found local injection of a fluid extremely effective in the cure of chronic peripheral sciatica. He has occasion to treat from fifty to sixty patients with sciatica every year, and since 1904 has been systematically applying these perineural injections. He ascribes the benefit to the mechanical distention of the parts, and thinks it is important to inject the fluid in a constant stream and under considerable pressure. Physiological salt solution is injected through a needle cannula from 7 to 8 cm. long, inserted at the point of the inner aspect of the thigh where the long head of the biceps femoris is crossed by the gluteus maximus. The patient must be in the knee elbow position; the cannula is introduced for half its length, and is then lowered a little and pushed in for 3 or 3.5 cm. farther. This brings the tip to the sciatic nerve at the point where it is most easily and safely reached without fear of injury of the soft parts, as he learned from experiments with colored fluids on the cadaver. The injected fluid enters the perineurilemma. When the needle reaches the sciatic nerve the leg twitches or there is sharp pain or paræsthesia in leg and foot. The tube connected with the syringe holding just 100 c.c. is attached to the cannula and the fluid is injected. The patient lies down for a half hour or so, and then goes home and rests for the next day or two. In a few cases the neuralgia recurs, requiring from two to four injections before the patient is entirely cured. In 62.6 per cent. of 67 cases the cure was complete; in 20.8 per cent. there was marked improvement, and in 8.9 per cent. no effect was apparent.

**The Administration of Magnesia in Gastric Affections** is discussed in the *Journal of the American Medical Association* for April 25. For gastritis with constipation the following is prescribed:

R Bismuth subnitrate, ..... ʒv;  
Magnesium oxide, ..... ʒi.

M. et fac chartulas xx.

Sig.: One powder three times a day before meals.

If there is hyperacidity of the stomach sodium bicarbonate is added as follows:

R Bismuth subnitrate, ..... ʒv;  
Magnesium oxide, ..... ʒi;  
Sodium bicarbonate, ..... ʒiiss.

M. et fac chartulas xx.

Sig.: One powder three times a day before meals.

If there is much gastric flatulence wood charcoal is substituted for the bicarbonate:

R Bismuth subnitrate, ..... ʒv;  
Magnesium oxide, ..... ʒi;  
Wood charcoal, ..... āā gr. lxxxv.

M. et fac chartulas xx.

Sig.: One powder three times a day after meals.

**Lactic Lemonade for Arteriosclerosis.**—In the *Journal of the American Medical Association* for May 2 the following formula is given for a drink to be taken by patients from arteriosclerosis several times a day, for a month or two.

R Sodium carbonate, ..... ʒiiss;  
Lactic acid, ..... ʒi;  
Addition, ..... ʒiiss;  
Simple syrup, ..... ʒi;  
Water, ..... ad ʒi.

transportation through the mail as second class matter.

NEW YORK, SATURDAY, MAY 23, 1908.

MERCURY IN THE TREATMENT OF  
CONSUMPTION.

While there should be no abatement of our present ardor in the employment of hygienic agencies in the treatment of tuberculous disease—preventive measures, pure air, sanitary homes, rest, nutritious food, and the like—the cry of “throw physic to the dogs” should not lead us to neglect all other resources, including the use of drugs, that may be of assistance in combating the disease. There are thousands of instances, indeed, in which it is difficult if not almost impossible to carry out the hygienic treatment in such a way as to give the patient even an approach to the benefit which ought to result from a full and fair employment of it. If in such cases there is a prospect of some benefit from the administration of drugs, by all means let us make use of them. More than ordinary interest, therefore, attaches to an article by Surgeon Barton Lisle Wright, of the navy, published in the April number of the *United States Naval Medical Bulletin*, in which weighty evidence is to be found of the efficacy of mercury in tuberculous disease.

It was by accident that Dr. Wright's attention was first drawn to the possibility of benefiting tuberculous individuals by the use of mercury. He tells us that three years ago, while he was on duty in a temporary camp for the tuberculous established in connection with the United States Naval Hospital in Pensacola, he had under his care several patients who were both tuberculous and syphilitic, and that under mercurial treatment their pulmonary lesions

improved much more rapidly than he had ever observed in pure tuberculous infections treated under similar or more advantageous climatic conditions, so that he was led to believe that the improvement was due to the antisyphilitic medication. With this idea in view he placed about ten men on the “mixed treatment.” They all improved until the treatment had to be discontinued by reason of the occurrence of gastrointestinal derangement, but before he could continue the experiment further he was ordered to sea. Early in the autumn of 1907, when he had gone on duty at the United States Naval Hospital, New Fort Lyon, Las Animas, Colorado, his colleague there, Passed Assistant Surgeon E. M. Brown, in the light of Dr. Wright's experience, tried the mercurial treatment on several pulmonary patients, but with only indifferent results. This, Dr. Wright now believes, was due to the fact that the doses of mercury given were not sufficiently large, for the same patients showed immediate and decided improvement under the use of larger doses.

Then, in about three months, Surgeon W. H. Bucher reported for duty, and took up with Surgeon Wright's idea enthusiastically, and the plan was promptly and heartily approved by Medical Inspector C. T. Hibbett, the commanding officer. At Dr. Bucher's suggestion it was determined to use injections of mercury succinimide, that compound having been found by him superior to other mercurials in the treatment of syphilis. About a month later an abstract of an article by Dr. Wolters, in the *Dermatologische Zeitschrift* for the preceding September, confirmed the confidence of our officers in the efficiency of antisyphilitic medication in the treatment of tuberculous disease. Intramuscular injections of the succinimide were settled upon, and the experiments proceeded. A few encouraging case reports are given.

Dr. Wright invites special attention to the following points brought out in his experiments and those of his associates: 1. The immediate improvement of the patients' general condition, as shown by slowing of the pulse, reduction of temperature, and gain in weight. 2. A conclusive demonstration that the treatment will cure extremely advanced tuberculous ulceration of the larynx and pharynx in a remarkably short period of time. 3. The fact that the treatment produces a decided improvement of advanced pulmonary lesions and also has an evident beneficial action on tuberculous glands. He notes that great care was taken to ascertain that the subjects were not syphilitic. Stress is laid upon the fact that large and increasing doses of mercury are required, and the statement is made that tuberculous persons are extremely tolerant of the drug, more so than syphilitics. When, however, the in-

fection is slight the large doses are not so well borne; in several cases an injection of 0.4 of a grain of the succinimide caused soreness of the gums and the dose had to be reduced. The idea is rather prevalent in the profession that the waters of Hot Springs, Arkansas, enable syphilitics to bear larger amounts of mercury than it would ordinarily be prudent to administer. Our Hot Springs friends may therefore find it advantageous to treat tuberculous patients with mercury and the waters.

### THE BACTERIOLOGY OF GENERAL PARESIS.

Of all the mental diseases, general paresis stands out as the most distinct and the most hopeless. From the days of Bayle to the present time steady advance has marked the progress in our understanding of this disease process, and in the comparatively recent monumental work of Alzheimer and Nissl it would appear that, from the pathological standpoint at least, this disease has found a firm underlying foundation and an anatomical interpretation for all time. *Ætiologically*, however, the view is still troubled. Notwithstanding the general conviction—founded on the insecurities of statistical analysis and the more thorough and apparently definitive findings of Wassermann and Plaut relative to the presence of a syphilitic antibody in the cerebrospinal fluid of most paretics—that syphilis is the fundamental *ætiological* factor, there still remain difficulties in the way of interpreting this disease solely in the light of its being a syphilitic final product acting on nervous tissues.

It is for this reason that the studies of Ford Robertson and the discovery of his so called *Bacillus paralyticus* have aroused considerable interest and given rise to protracted discussions, the latest of which took place at a recent meeting of the American Medicopsychological Association.

The scientific world has not accepted the Ford Robertson findings, nor yet is it prepared to accept the therapeutical results alleged by him and his followers in this and other countries; yet the contentions are entitled to be heard and the evidence reviewed. At the meeting in question, Dr. John D. O'Brien, of Massillon, Ohio, reported some further observations on the *ætiology* and treatment of general paresis, in which he reasserted his belief in the causal relation of the pseudodiphtheroid *Bacillus paralyticus* to paresis, and also reported some measure of success in the treatment of this disease by "vaccines" prepared from this organism. Work done in the Cincinnati Sanatorium under the direction of Dr. F. W. Langdon, confirmatory of Dr. O'Brien's position, was also brought forward. On

the other hand, in an exhaustive analysis of some of the bacteriological findings, post mortem and ante mortem, in one hundred cases of mental disease of various types. Dr. E. P. Gay, Dr. E. T. Richards, and Dr. E. E. Southard, of Hathorne, Mass., established the facts that terminal infections were very frequent in mental disorders, and that a vast variety of organisms might be found. More particularly it was shown by their studies that members of the pseudodiphtheria group, to which *Bacillus paralyticus* belongs, are very frequent saprophytes, being found in the skin, bronchial mucous membrane, and genitourinary tract, and even occurring in epidemic frequency in certain laboratories under diverse conditions. They were unable to find this organism in the cerebrospinal fluid in paretics, living or dead, and when found it could be established that such findings resulted only as a result of faulty technique.

In the discussion it developed that other workers had come to the same conclusions—that, from personal observation, the work of the Scotch bacteriologist did not come up to the technical requirements of exact bacteriology, and the general conclusions drawn were that it was not proved that the *Bacillus paralyticus* had any relation to general paresis; that, if it had, it was a saprophyte that perhaps played a part in causing a secondary septicæmia in paretics; and that the therapeutical deductions might have some value relative to the treatment of such secondary infections, but had no real relation to the underlying process. From this latter standpoint further studies were thought to be desirable.

### THE EXPERIMENTAL TREATMENT OF TRYPANOSOMIASIS IN RATS.

In the treatment of trypanosome infection in rats it has been found that a number of substances will cause the parasites to disappear from the peripheral blood for a time, but that after a varying period of freedom the blood will again be found to contain numerous parasites. Certain arsenical preparations gave the best results in quickly ridding the peripheral blood of the parasites and in keeping it free from them for the greatest period of time. It was subsequently found that the administration of a mercury salt after the trypanosomes had disappeared from the peripheral blood would in many cases permanently cure the infection. In many of the animals, however, death took place from the organic degenerations produced by the remedies. A committee of the Royal Society has been engaged in studying the subject, and in the *Proceedings of the Royal Society*, vol. LXXX, No. B 530, Plummer and

Thomson report for this committee. They have found that the salts of mercury have not given altogether satisfactory results, on account of the chronic kidney and liver lesions produced. Although they say that in the more chronic form of trypanosomiasis, such as *Trypanosoma gambiense* infection, this treatment might be more successful than in the more acute infections with *Trypanosoma Evansi* and *Trypanosoma Brucei*.

Since treatment with arsenic compounds was only partially successful, they turned their attention to antimony compounds. They first used antimony glycine without encouraging results; then they employed potassium antimonyl tartrate, but it killed the animals in a short time. They then used sodium antimonyl tartrate in one per cent. solution. They found that this substance had the most marked influence upon the trypanosomes in the living body of any of the various substances so far used, including the arsenical preparations which had given such good results in the past experiments. The injections caused no pain and produced no inflammatory reaction, and the trypanosomes disappeared from the peripheral blood with great rapidity. Thirty-nine rats infected with *Trypanosoma Evansi* and *Trypanosoma Brucei* were treated with this compound. Some of them died from other diseases than trypanosome infection, and a satisfactory percentage were living at periods varying from twenty-one to fifty-two days after the beginning of the diseases.

#### THE FORTHCOMING MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

Hardly will this issue of the *Journal* have reached our remote subscribers when it will be time for them to start for Chicago to attend the approaching meeting of the American Medical Association. We take it for granted that a goodly proportion of them will go, even irrespective of membership in the association, for the profession at large is always interested in the meetings and in the concomitant events. Moreover, Chicago, "the Empress of the West," as the late Dr. Gaillard Thomas called the city, could not be seen to better advantage by medical men and their families than on the occasion of such a great gathering of their own solidarity.

The comparatively central situation of Chicago and its ready accessibility invite a large attendance, and the city is so large and so well provided with hotels that nobody who goes to the meeting need be at a loss to find suitable quarters. It is usually an attractive place in the month of June, and we may be sure that its hospitable inhabitants will exert themselves to the utmost to provide entertainment for their visitors. From the scientific point of view,

apart from the proceedings of the various sections of the association, the clinical work announced is on an unusually large scale, and the pathological exhibit will probably be more extensive than it has been heretofore. Chicago is one of the great centres of activity in science as well as in trade, and it is to be expected that much that is not formally announced in connection with the meeting will be found inviting to visiting physicians. All things considered, it will be seen that the Chicago meeting promises to be exceptionally large and profitable.

#### PROSPERITY BY SUGGESTION.

The psychology of suggestion is undoubtedly an important factor in all the relations of life, and we are interested to note that it is proposed to use it systematically with a view to improving the present commercial and financial conditions. So far as purely physical factors are concerned, the United States is in a prosperous condition. As a result of wildcat speculation, carried out in many instances with other people's money, a financial crisis was brought about in New York, requiring a readjustment based on real and not inflated values of incorporated securities. Out of this readjustment, however, there was developed a certain pessimistic tendency which had a very real effect on commercial conditions, as can be testified to by many physicians, who have felt it either directly, in their own investments, or indirectly, through the influence on the incomes of their patients. To counteract this pessimistic attitude an organized movement has been set on foot by various associations of commercial travelers, who will hold an Interstate Prosperity Congress in New York during next August. In St. Louis an organization has also been formed under the title of the National Prosperity Association, the object of which is to restore confidence among business men.

The movement has been treated lightly by some of the newspapers, and in one particular paper has been characterized as an effort of the commercial world to lift itself by its own bootstraps. We do not think that this characterization is justified. If the substantial basis of prosperity exists, as is asserted by the officials of the prosperity crusade, and if the only obstacle to a return of commercial and financial prosperity is lack of confidence, such organized efforts as are being put forth to restore confidence hold out much promise of good. Psychologists have come to recognize clearly the importance of suggestion in the creation of mental conditions, and the psychology of mass action as seen in crowds is well known. It has been clearly shown in these studies of the psychology of the

crowd that there are action and interaction by suggestion which make it possible for the individuals in a crowd to reach a state of exaltation or fervor which they would be incapable of reaching were the same influences brought to bear on them as isolated individuals. This idea is worked out with considerable elaboration in an interesting drama now on the New York stage, *The Witching Hour*. In this play a wave of horror and repulsion which sweeps over the entire community at the disclosure of certain facts affects the decision of a jury, the members of which have no knowledge of the facts bringing about this feeling of repulsion, though they are unconsciously affected by it.

By all means, therefore, let the commercial world make this essay in suggestion, for if confidence is the only element of prosperity lacking, it would seem well within the bounds of possibility that through some concerted movement of this kind confidence might be restored. While it will not be possible for the psychologist to exercise that control over the various factors in the experiment required to place the results on a really scientific basis, the results will still have a certain scientific as well as a commercial interest.

### A WELL DESERVED PENSION.

It is announced from Washington that the House of Representatives has unanimously voted a life annuity of \$125 a month each to the widow of the late Major James Carroll, of the Medical Department of the United States Army, and to the widow of the late Acting Assistant Surgeon Jesse W. Lasear. Both those gentlemen, as our readers are well aware; lost their lives in consequence of experimental work that has proved of incalculable value in the prevention of disease and added lustre to the medical corps of the army.

### Obituary.

JOHN DUTTON STEELE, M. D.,  
of Philadelphia.

Dr. Steele, who was born in Pottstown, Pa., on February 21, 1868, died in Wayne, Delaware County, Pa., on Sunday, May 17th, aged forty years. In 1888 he received the degree of A. B. from Williams College, and in 1893 he was graduated from the Medical Department of the University of Pennsylvania. Dr. Steele, on the occasion of his graduation from the latter institution, received the alumni medal for the highest general average in the examinations of the course. He went to the Philadelphia General Hospital as interne soon after his graduation, and, after completing a full term in that institution, spent some time in Germany and Austria studying internal medicine and pathology.

Upon his return to this country, after his period of European study, Dr. Steele engaged in the practice of his profession. He became connected with the Department of Medicine of the University of Pennsylvania, where he was assistant demonstrator of gross morbid anatomy, instructor in medicine, and associate in medicine successively. He also became associated with the Presbyterian Hospital, in which institution he was clinical pathologist and visiting physician successively. Dr. Steele was a member of the Association of American Physicians, a fellow of the College of Physicians of Philadelphia, a member of the Philadelphia Pathological Society, a member of the Philadelphia County Medical Society, of the Medical Society of the State of Pennsylvania, and of the American Medical Association.

Dr. Steele's writings were principally on subjects pertaining to the diseases of the gastrointestinal tract. He had contributed to many discussions at the various medical societies to which he belonged and to many medical journals. In association with Dr. S. J. Repplier he presented a paper at the meeting of the Association of American Physicians in Washington on May 12th on the Value of Intestinal Antiseptics, which was read by title owing to his illness. Dr. Steele had many friends, whom he made and held by his pleasant personality and engaging manners, who will sincerely regret his untimely death.

### News Items.

**Changes of Address.**—Dr. C. T. Graham Rogers, from 104 East Ninety-sixth street to 1333 Lexington avenue, New York; Dr. H. Greenstein, from 341 East Fifty-second street to 147 West One Hundred and Forty-third street, New York.

**Buffalo Academy of Medicine.**—The Section in Pathology met on the evening of Tuesday, May 19th. The chief feature of the programme was a paper on the care of the municipal milk supply, with a lantern slide demonstration, by Dr. George W. Goler, Commissioner of Health of Rochester, N. Y.

**Scientific Society Meetings in Philadelphia for the Week Ending May 30, 1908.**—Monday, May 25th, Mineralogical and Geological Section, Academy of Natural Sciences. Tuesday, May 26th, Philadelphia County Medical Society. Thursday, May 28th, Pathological Society; Section Meeting, Franklin Institute.

**Contagious Diseases in Chicago.**—During the week ending May 9, 1908, there were 270 cases of contagious diseases reported to the Department of Health, of which 33 were of measles, 30 of scarlet fever, 46 of diphtheria, 28 of tuberculosis, 35 of typhoid fever, 21 of whooping cough, 20 of mumps and 4 of erysipelas.

**The Tricounty Medical Society of South Jersey** will hold its next regular meeting at the Schaefer House, Salem, N. J., on Tuesday, May 26th, at 10 a. m. The society include the counties of Gloucester, Salem and Cumberland. The officers are: President, Dr. W. H. James, of Pennsville; first vice president, Dr. J. H. Moore, of Bridgeton; second vice president, Dr. H. B. Diverty, of Westbury; secretary and treasurer, Dr. George Edgar Rindley, of Westbury.

**Officers of Association of American Physicians.**—At the annual meeting of this association, which was held in Washington last week, the following officers were elected for the coming year: President, Dr. Victor C. Vaughan, of New York; vice president, Dr. Harvey Amos, of Albany, N. Y.; secretary, Dr. George M. Kohn, of Washington, D. C.; treasurer, Dr. S. Schaffer, of Philadelphia; treasurer, Dr. J. P. Crozer Griffith, of Philadelphia; councilor, Dr. S. J. Meltzer, of New York.

**Charitable Bequests.**—The St. Louis Children's Hospital receives \$500 by the will of Mrs. Clara E. Curtis, and \$300 by the will of Mrs. Georgiana C. Louderman. The latter bequest will be devoted to the equipment of a new dispensary at the hospital, and the bequest of Mrs. Curtis will be used to endow a bed for five years.

By the will of Mrs. Lavinia Hunting, of Malden, the Manhattan Eye and Ear Infirmary, New York, and the Cullis Consumptives' Home, Boston, receive \$3,000 each.

**The Silver Anniversary of the German Poliklinik.**—The twenty-fifth anniversary of the founding of the German Poliklinik, 137 Second avenue, New York, was celebrated on the evening of May 16th with a dinner at the Waldorf-Astoria. Dr. Samuel Kohn, Dr. H. J. Boldt, Dr. A. H. von Ramsdohr, and Dr. Ludwig Weiss, the four surviving doctors of the original fifteen who established the institution, were the guests of honor. In its twenty-five years of existence the Poliklinik has treated nearly a million persons free of charge.

**Plague in Venezuela.**—According to press dispatches, the plague situation in Venezuela has assumed an alarming aspect. The city of La Guayra is under strict quarantine, and quarantine regulations against Venezuelan ports have been ordered by Colombia and Trinidad. Daily bulletins are issued in Caracas purporting to give the number of deaths, and it is reported that in La Guayra there are from fifty to seventy deaths a day. The authorities are doing everything in their power to stamp out the plague, but their efforts so far seem to have had little effect.

**The Harlem Eye, Ear, and Throat Infirmary.**—Plans have been filed for a new two story and basement building for this institution, which is to be erected at the corner of Lexington avenue and One Hundred and Twenty-seventh street, at a cost of \$25,000. Ground was broken on May 14th, and the work on the new building will be pushed forward as rapidly as possible. The Harlem Eye, Ear, and Throat Infirmary was founded in 1881 by Dr. R. E. Swinburne. It treats about six thousand patients annually. Dr. C. D. Meding is executive surgeon of the institution.

**The Mortality of Chicago.**—During the week ending May 9, 1908, there were 531 deaths from all causes reported to the Department of Health, as compared with 717 for the corresponding period in 1907. Of the total number of deaths, 312 were of males, and 219 of females. The annual death rate in 1,000 of population was 12.78. The principal causes of death were: Apoplexy, 10; Bright's disease, 23; bronchitis, 14; consumption, 77; cancer, 26; convulsions, 7; diphtheria, 7; heart diseases, 48; influenza, 5; intestinal diseases, acute, 25; measles, 10; nervous diseases, 20; pneumonia, 77; scarlet fever, 2; suicide, 13; typhoid fever, 4; violence (other than suicide), 13; whooping cough, 2; all other causes, 148.

#### Infectious Diseases in New York:

*We are indebted to the Bureau of Records of the Department of Health for the following statement of new cases and deaths reported for the two weeks ending May 16, 1908:*

	May 9.	May 16.	May 9.	May 16.
Cases.	Deaths.	Cases.	Deaths.	
Tuberculosis pulmonalis ..	53	187	143	18
Idiopathic ..	294	47	409	36
Muscles ..	1,668	47	1,513	35
Scarlet fever ..	968	43	1,072	41
Smallpox ..	..	..	1	..
Measles ..	136	..	134	..
Typhoid fever ..	32	8	25	6
Whooping cough ..	32	5	37	4
Cerebrospinal meningitis ..	8	7	10	11
Total ..	3,696	332	3,798	291

**The Society for the Study of Inebriety, Alcohol, and Other Narcotics.**—The thirty-eighth annual meeting of this society will be held in the Auditorium Hotel, Chicago, on June 2d, 3d, and 4th. There will be one session each day, from 9 a. m. to 12 m. The programme includes more than twenty papers which will be read and discussed by prominent members of the medical profession, and the meeting promises to be one of great interest. A "temperance lunch" will be served at the hotel on Wednesday, June 3d, at 1:30 p. m., which will be the occasion for an informal discussion of the alcohol problem. Dr. T. D. Crothers, of Hartford, Conn., secretary of the society, has charge of this "lunch meeting," and will be glad to furnish programme and any information desired regarding the meeting.

**Philadelphia's Two Hundred and Twenty-fifth Anniversary** celebration will include notable observances by medical men, as will be seen by the programme for "Medical Day" which has just been issued. On Tuesday morning, October 8th, at 11 o'clock, in the Academy of Music, the following addresses will be delivered: The College and Allied Institutions of Philadelphia, by Dr. George A. Pier-sol; The Great Hospitals of Philadelphia, by Dr. J. Chalmers Da Costa; The Development of Practical Medicine in Philadelphia, by Dr. James M. Anders.

**Personal.**—Dr. John M. Swan, of Philadelphia, has been appointed secretary for the United States of the Section in Tropical Medicine of the Fifth Pan-American Medical Congress, which will be held in Guatemala City, Guatemala, August 5th to 10th.

Dr. Louis Faugères Bishop and Mrs. Bishop will sail for Europe on June 17th. They intend to spend the summer in Nannheim, Germany, returning to New York early in September.

Dr. H. B. Roop, of Columbia, Pa., is registered at the Philadelphia Polyclinic and College for Graduates in Medicine.

On the afternoon of Tuesday, May 19th, Dr. Charles E. Beavor, of London, delivered, by invitation, a lecture on the Methods of Examining Muscular Movements, at the Hospital of the University of Pennsylvania.

#### Society Meetings for the Coming Week:

**MONDAY, May 25th.**—Medical Society of the County of New York.

**TUESDAY, May 26th.**—New York Dermatological Society (annual); New York Medical Union; New York Otological Society; Metropolitan Medical Society of New York City; Buffalo Academy of Medicine (Section in Obstetrics and Gynecology).

**WEDNESDAY, May 27th.**—New York Academy of Medicine (Section in Laryngology and Rhinology); New York Surgical Society.

**THURSDAY, May 28th.**—New York Academy of Medicine (Section in Obstetrics and Gynecology); Brooklyn Pathological Society; Hospital Graduates' Club, New York (anniversary); New York Celtic Medical Society; Brooklyn Society for Neurology.

**The Health of Pittsburgh.**—During the week ending May 2, 1908, the following cases of transmissible diseases were reported to the Bureau of Health of Pittsburgh: Chickenpox, 7 cases, 0 deaths; typhoid fever, 38 cases, 1 death; scarlet fever, 16 cases, 1 death; diphtheria, 12 cases, 3 deaths; measles, 175 cases, 8 deaths; whooping cough, 14 cases, 0 deaths; pulmonary tuberculosis, 25 cases, 10 deaths. The total deaths for the week numbered 140 in an estimated population of 403,330, corresponding to an annual death rate of 18.04 in 1,000 of population.

During the week ending May 9, 1908, the following cases of transmissible diseases were reported: Chickenpox, 4 cases, 0 deaths; typhoid fever, 26 cases, 2 deaths; scarlet fever, 31 cases, 0 deaths; diphtheria, 7 cases, 3 deaths; measles, 260 cases, 2 deaths; whooping cough, 6 cases, 2 deaths; pulmonary tuberculosis, 31 cases, 15 deaths. The total deaths for the week numbered 160 in an estimated population of 403,330, corresponding to an annual death rate of 20.62 in 1,000 of population.

**Increased Pay for Naval Officers.**—A bill has been signed by the President providing for increased pay for officers and men of the Navy, which, according to the members of the Committee on Military Affairs, puts the officers of the Navy on a parity with those of the Army under the new army appropriation bill. The bill fixes the remuneration of commissioned officers on the active list at the following figures: Lieutenant, junior grade, \$2,000; lieutenant, \$2,400; lieutenant commander, \$3,000; commander, \$3,500; captain, \$4,000; rear admiral, second nine, or commodore, \$6,000; rear admiral, first nine, \$8,000. Each officer below the rank of rear admiral receives 10 per cent. of his current year's pay for each term of five years' service in the Army, Navy, and Marine Corps, in addition to his annual pay, provided that the annual pay of a captain shall not exceed \$5,000 per annum; of a commander, \$4,500 per annum; and of a lieutenant commander, \$4,000 per annum. Furthermore, officers are to receive an allowance of 10 per cent. additional when on sea duty or on shore duty beyond the continental limits of the United States.

**Details of the Army Pay Bill.**—The army appropriation bill contains many features which are of interest to the members of the medical corps. Among these are the authorization of the secretary of war to contract for the care, maintenance, and treatment, at any asylum in the Philippine Islands, of insane natives serving in the Army. The appropriation for the hospital corps amounts to \$955,840, of which \$100,000 is for length of service; for the medical corps, \$816,300, of which \$130,000 is for additional pay; for miscellaneous hospital matrons, \$9,000; superintendent of the nurse corps, \$1,800; female nurses, \$55,020; for hospital stewards, \$543,366; for quarters for hospital stewards, \$75,000; for medical supplies, \$700,000; for special apparatus, \$200,000; for museums and laboratories, \$5,000; and for the surgeon general's library, \$10,000. The total appropriation for the Army, including the items mentioned, amounts to \$95,382,246.61. The bill includes an appropriation of \$1,000,000 for heavy furniture for permanent use in the officers' quarters.

**The Health of Philadelphia.**—During the week ending May 2, 1908, the following cases of transmissible diseases were reported to the Bureau of Health: Typhoid fever, 68 cases, 14 deaths; scarlet fever, 61 cases, 5 deaths; smallpox, 2 cases, 0 deaths; chickenpox, 31 cases, 0 deaths; diphtheria, 79 cases, 9 deaths; cerebrospinal meningitis, 1 case, 0 deaths; measles, 504 cases, 17 deaths; whooping cough, 25 cases, 5 deaths; pulmonary tuberculosis, 125 cases, 64 deaths; pneumonia, 72 cases, 51 deaths; erysipelas, 6 cases, 1 death; puerperal fever, 6 cases, 7 deaths; mumps, 34 cases, 0 deaths; cancer, 20 cases, 21 deaths. The following deaths were reported from other transmissible diseases: Tuberculosis, other than tuberculosis of the lungs, 10; diarrhoea and enteritis, under two years of age, 15. The total deaths for the week numbered 513 in an estimated population of 1,532,738, corresponding to an annual death rate of 17.40 in 1,000 of population. The total infant mortality was 107; under one year of age, 74; between one and two years of age, 33. There were 49 still births, 24 males, and 25 females.

**Meetings of Sections of the New York Academy of Medicine.**—The Section in Ophthalmology met on Monday evening, May 18th. After the presentation of patients by Dr. J. E. Giles and Dr. H. H. Tyson, Dr. Edwin Torok read a paper entitled *The Diagnostic and Therapeutic Value of Tuberculin in Tuberculous Eye Diseases*.

The Section in Medicine met on Tuesday evening, May 19th. Among the cases presented for discussion were an unusual case of diabetes mellitus, by Dr. T. C. Janeway, and a case of myelogenous leucemia with unusual perlepenitis, by Dr. N. S. Patterson. Dr. C. A. McWilliams read a paper on *Acute Dilatation of the Stomach*.

On Wednesday evening, May 20th, a meeting of the Section in Genitourinary Surgery was held. Dr. Charles Goodman reported a case of papilloma of the bladder. Dr. John Van der Poel presented specimens of hydrocele sac containing atrophic testis and of teratoma testis. Dr. Hiram N. Vineberg read a paper entitled *Pyelitis in Pregnancy and in the Puerperium*, which was followed by a general discussion.

A meeting of the Section in Laryngology and Rhinology will be held on Saturday evening, May 23d, at 8:15 o'clock. The programme includes the following papers: *Some Essential Principles in the Surgery of the Normal Accessory Sinuses*, by Dr. John F. Barnhill, of Indianapolis, Ind.; *Frontal Sinus Diseases*, by Dr. Albert Jansen, of Berlin, Germany. Among those who will take part in the discussion are Dr. Robert C. Myles, Dr. T. P. Berens, and Dr. Felix Cohen.

The Section in Orthopaedic Surgery will hold no meeting this month.

A meeting of the Section in Ophthalmology and Genitourinary Surgery will be held on Thursday evening, May 21st, at 8:15 o'clock. Dr. Ralph W. Wood will read a paper on *Some Cases of ruptured aneurysm after two Cesarean sections*. Dr. Ralph W. Wood will present a specimen of a dissected aneurysm of the right artery from a child of nine years. Dr. Edgar C. Wood will read a paper on *Supraventricular tachycardia in successive pregnancies*. Dr. H. A. Miller, of Pittsburgh, Pa., will read a paper on *Artificially induced abortion by the method of controlling the uterine blood supply by means of Phosphorus Compound*. Dr. F. L. W. will read a paper on *Postpartum Eclampsia*, based on the report of a case.

1. A Comparative Study of Tsutsugamushi Disease and Spotted or Tick Fever of Montana,  
By P. M. ASHBURN and CHARLES F. CRAIG.
2. A Study of the Value of the Measurements of Chest Expansion,  
By HARRY W. GOODALL and J. LYMAN BELKNAP.
3. The Extraintestinal Origin of Hydrobilirubin,  
By A. E. AUSTIN and MABEL D. ORDWAY.
4. A Lipoma from the Brachial Plexus: A Review of Some of the Rare Cases of this Tumor,  
By W. P. CARR.

#### 1. A Comparative Study of Tsutsugamushi Disease and Spotted or Tick Fever of Montana.

—Ashburn and Craig come to the conclusion that a consideration of the facts concerning the two diseases as at present known justifies the opinion that they are separate and distinct disease entities; they present many points of semblance, but not enough of them to overbalance those of difference. According to Tanaka the name *tsutsugamushi* has been known since the earliest historical times, while the name *shashitsu* occurs in old Chinese writings of more than a thousand years ago. A quotation from one such writing indicates that at that time the disease was recognized as a distinct affection and was ascribed to the bite of a mite which occurred in summer time in certain districts that had been flooded by the spring rains. The bite was described and the statement made that after three days high fever developed and a pustule appeared at the site of the injury. It was also recognized that only certain regions were infected, and that the disease only appeared in persons entering them. The disease was brought to the attention of the Western world by Palm, in 1878, and Bälz, in 1879, and since that time it has been the subject of much painstaking work by Japanese medical men and of numerous articles in Japanese and some in foreign journals. Numerous microorganisms, including cocci, bacilli, and protozoa, have been described as the cause of the disease, and several investigators are working at the present time, each with what he thinks the causative factor. It cannot be said that any of these workers has yet established his allegations. Three hypotheses at present divide the workers and rule the work of investigation: 1. That the disease is due to a bacterium, a belief favored by the workers of the Institute of Infectious Diseases. 2. That it is a protozoal infection. Professor Ogata is the leading exponent of this idea. 3. Tanaka thinks the disease due to a toxine contained in the body of the red mite. *Spotted fever* of Montana has been recognized for only a few years, twenty-five at the most, while the literature relating to it has practically all been made since 1902. At that time Wilson and Channing published their first account of it and their ideas as to its cause and method of transmission, in a preliminary report to the Montana State Board of Health. Mayor Wood, in 1888, and May, in 1889, reported a similar, or the same, disease in Idaho, but the form occurring there presents great points of difference, particularly in regard to mortality. It occurs in very strictly limited areas, particularly in a strip of country about 100 to 200 miles wide and

fifty miles long, lying on the west side of the Bitter Root River and the eastern side of the Bitter Root Mountains, and partly on the slopes of these mountains. The country in question has a considerable snowfall and the snow remains on the mountains until mid June and on the highest peaks two or three weeks longer. The Bitter Root River is largely fed from this snow, and, as it begins to melt in March and continues to do so with increasing rapidity until most of it has disappeared, the stream is in a state of freshet during that time and does not again reach "low water" until July. During the same period ticks, *Dermacentor occidentalis*, which before and after it are infrequently seen, appear in great numbers, particularly in the woods, thickets, and uncultivated regions. Likewise, and, as a rule, during the same period, cases of spotted or tick fever appear, and in almost all cases there is a history of a recent visit to, or residence in, the infected district, and, in many cases, of tick bites received there. It may be said that the disease is introduced by the bite of *Dermacentor occidentalis*. A consideration of the ætiology of the two diseases shows many points of resemblance, but also differences. Both occur in small and usually strictly limited areas along certain streams running through mountainous country. The country in each instance is subject to heavy snowfall in winter and the streams to spring or summer floods. Along each infected stream the dangerous spots are usually more or less uncultivated and the soil overgrown with underbrush, trees, or weeds, while the immune spots are well cultivated. In each instance the disease is attributed to the bite of an *Acarina*, and in each a supposed protozoan blood parasite has been described as the cause and has not been confirmed as such. Contagion is unknown in either disease. The differences in the ætiology of the two are equally well marked. The *Acarina* whose bite causes *tsutsugamushi* is always a six legged, larval *Trombidium*, whose adult form is unknown. That causing spotted or tick fever of Montana is always *Dermacentor occidentalis*, and usually the adult. *Tsutsugamushi* disease occurs always after floods, and it is contracted on ground which has actually been submerged by the swollen river. Fields immediately adjoining the infected areas and but a few feet higher are considered safe. The Montana disease may precede the flooding of the streams, or, more usually, accompanies it. It is very commonly contracted on ground which has not been submerged, but is on hillsides high above the level of the river. The cases begin in March and rarely appear after the middle of July. *Tsutsugamushi* disease is beginning to appear at that time and continues to do so into October.

3. **The Extraintestinal Origin of Hydrobilirubin.** Austin and Ordway state that when no bile enters the intestine (absence of urobilin in feces and urine) urobilin may occasionally be found in fistula bile. This is not due to the conversion of bilirubin to urobilin by the blood; what effect cells actively may have upon it we do not know. It is evident that the liver does not form urobilin, or it would be oftener found when complete closure of the common duct occurs. If urobilin is ever regenerated to bilirubin, it is probably not an oxidative process, as so often stated. As cholecystitis is often accompa-

nied by bacterial infection of the gallbladder, from which these germs may easily make their way into the liver and there exercise their functions as in the intestines, the query appears a just one, if the formation of urobilin other than in the intestine may not be due to bacterial infection.

7. Rapid and Aseptic Anastomosis of the Hollow Viscera by a New Method, By E. WYLLYS ANDREWS.

2. **Coagulation of the Blood.**—Robertson, Illman, and Duncan find that during the febrile stage of the infectious diseases coagulation is noticeably retarded. The clinical employment of the calcium salts has no direct or invariable effect on the coagulation time of the blood, either in large doses one hour after its administration or in small or large doses at any subsequent period, even extending over two or more weeks. In their hands the calcium content of the blood, as determined in terms of ammonium oxalate, proved unreliable. They were unable to show definite relationship between leucocytosis and coagulation time. Nucleic acid uniformly failed to produce an increase in the number of leucocytes and also failed to hasten coagulation. But the reaction of the coagulation time to hæmorrhage was shown conclusively. Though not as striking as some of their other results, they have been able to show that citric acid prolongs the coagulation time, and it seemed, even when the difference in time before and after its use was not a very material one, that the viscosity of the blood was lessened.

4. **Acute Glanders in Man.**—Meyer and Crohn say that in a typical case, with a good history the diagnosis should not be difficult, if one has the disease in mind. Acute glanders in man is seen so seldom that it is usually not even thought of, especially when there is little in the way of skin lesions. A bad coryza, which may be the most marked local sign of glanders, is, of course, often present in grip or pneumonia. Many of the cases recorded in the literature, in which mistaken diagnoses were made, showed neither coryza nor skin lesions at the onset, this being often characterized by chill, followed by typical symptoms of pneumonia or grip or by joint symptoms simulating rheumatism. Only after a variable time has elapsed does there appear nasal symptoms or a skin eruption which suggests the possibility of glanders in any case. When, however, with a more or less septic condition, there appear on the skin indurated painful reddened areas with soft centres, with less tendency to

rupture than ordinary abscesses, and which, when opened, discharge a thin, serosanguinous material, the resulting ulcer having a necrotic base, usually involving muscle, and with no tendency to heal, glands should be thought of, and all the means at our disposal should be made use of in aiding us to reach a correct diagnosis. The injection of malein, which is employed in diagnosing incipient or latent glands in horses, is of no service in an attack of suspected acute glands in man, as a positive diagnosis depends mainly on a rise of temperature (in addition to a local reaction), and this is always present. They have heretofore depended on finding the *Bacillus mallei* in the cultures, and in the typical results obtained by inoculation. These means will, in practically all cases, enable us to reach a diagnosis, but they are time consuming, requiring from one to three days to furnish results. Recently a new method of arriving at a diagnosis has been devised, one based on the phenomenon of agglutination and precipitation, and, therefore, similar to the Widal test in typhoid. This method, according to the report, is used officially in the diagnosis of glands in horses, in Austria and Prussia, and is considered fairly accurate.

**6. The Successful Treatment of Catarrhal Deafness.**—Jervoy describes the method of treatment which he uses: After thorough cocaineization, the operator, facing the patient and slightly to his right, passes the right index finger (palm of the hand up) through the mouth, behind the soft palate and into the postnasal space. After locating the landmarks of the space, the finger tip is placed over the top of the cartilaginous ring of the tubal orifice into the upper end of the crescentic fossa. Pressing the finger firmly and deeply into the fossa, it is swept backward and downward throughout the fossa's length, breaking down all resisting tissues, repeating the movement if necessary, and not failing to break up the mass of granulations which frequently occupies the extreme lower end of the fossa behind the posterior faucial pillar. By inclining the finger to the opposite side it can then be treated in the same fashion, thus attending to both sides without withdrawing the finger. After the bleeding, which is usually slight, has ceased a cotton tipped, curved, postnasal probe, dipped in a five to ten per cent. silver nitrate solution or a thirty per cent. argyrol solution, is firmly swept through the fossa. This application should be repeated every forty-eight hours for ten days or two weeks. The results are excellent, sometimes brilliant, even apparently miraculous, and often immediate. The author has several times seen the hearing of a patient improve from 200 to 300 per cent. within a half hour of the operation. The improvement is a permanent one, which usually improves still further under persistent catheterization and routine applications. The latter should always be carried out faithfully in these cases. The diagnosis of the condition is easy by means of the rhinoscopic mirror. Occasionally, when the fossa are almost or quite filled with formations which happen to present a more or less smooth surface, the appearance will be that of very shallow or absent fossa. A mistake should not be made. The fossa is never absent and never very shallow in the adult. At

least three eighths of an inch of natural depth is always present, and sometimes considerably more. The granulations or glandular hypertrophies sometimes extend down below the end of the fossa, and appear, on oral examination, as reddish elevations or thickenings just behind the posterior faucial pillar. This appearance is often given the name of lateral pharyngitis, and its treatment by the ordinary routine has heretofore been rather unsatisfactory. If the patient has a wide open nostril all the way through, anterior rhinoscopy will show a limited excursion of the tubal orifice during the act of swallowing. Inspection of the tympanic membranes will show a lessened or absent light reflex, a ground glass, lustreless appearance, with more or less depression. The hearing will usually be perceptibly dulled, and if the condition is of long standing it may be almost lost. Bone conduction of sounds will be good, while air conduction is seriously impaired, showing that the disorder is of the passages and not of the perceptive apparatus.

5. The Problem Which Confronts the Otologist in the Treatment of Chronic Catarrhal Deafness. By CAROLUS M. COBB.
6. Nitroglycerin in the Treatment of Neuritis. By H. BERTON STEVENSON.

**1. The Occurrence of Epileptiform Attacks in Diabetes Mellitus.**—Conner remarks that, although some of the epileptiform attacks which occur in the course of diabetes are manifestly due to other associated conditions (uræmia, cerebral softening, meningitis, etc.), a certain proportion of them are unquestionably related directly to the diabetes itself, and are the expression of some form of diabetic intoxication. Such attacks may simulate closely the general convulsions of true epilepsy, or they may be distinctly Jacksonian in character and be limited to one side of the body or to certain groups of muscles. These localized convulsions are usually associated with transient paralysis of the affected muscles, aphasia, sensory disturbances, or other symptoms suggestive of a circumscribed brain lesion, and may thus lead to serious errors in diagnosis. The convulsions may appear only during the terminal coma, or they may be repeated at frequent intervals for days or weeks before coma develops, or, finally, they may cease with improvement of the diabetic symptoms. The association of such epileptiform attacks with the signs of acid intoxication is by no means constant. It seems probable, therefore, that the cause of the convulsive attacks must be sought for in some other form of diabetic intoxication.

**2. The Surgical Treatment of Alveolar Pulmonary Emphysema.**—Goodman and Wachsmann have adapted Freund's mode of operation.

The pathological findings are that the costal cartilages are of a dirty yellow color, in a state of fibrillation and cystic, showing also calcareous deposits which cause them to become increased in size; they are hardened, brittle, and devoid of their normal elasticity. In the presence of such changes, the proper excursion or motion of the corresponding ribs is interfered with. The cartilages of the second and third ribs of the right side are most frequently involved, but these changes may involve all the costal cartilages. The first cartilage, however, is rarely, and then usually the last, to be involved in this disease. With the degeneration of the cartilages and the accompanying rigidity of the ribs, the sternum is forced outwards and contributes eventually to the formation of the rigid barrel shaped thorax, which retains the lung in a continued state of distention. With the increase in the diameters of the chest, the normal function of the diaphragm is interfered with, and the muscle shows evidences of atrophy and fatty degeneration. By removing or resecting the offending cartilages, the proper functioning power of the chest may be restored; the ribs will be permitted to exercise their proper range of motion, and the proper expiratory efforts of the lungs will be facilitated. They have found that Freund's operation is of great benefit in emphysema with a rigid dilated condition of the thorax. A most convincing feature of this treatment is observed during operation; when the costal cartilage is resected the rib recedes immediately, at times below the level of the sternum. The ribs move so freely that the finger tip is distinctly squeezed when inserted between the sternum and rib. The lung visibly contracts. Relief may be afforded by operating upon one side. The operation is not dangerous, and is not followed by shock. Cardiac insufficiency, asthma, chronic bronchitis, and albuminuria are not necessarily contraindications of the operation. The best results are likely to follow, however, when the operation is undertaken before complications have arisen. A removal of, or a plastic operation on, the perichondrium of the resected cartilages seems imperative in order to obtain lasting improvement.

**4. Air Borne Infections.**—Bryant says that the evidence accumulated for many years, proving that air borne infections are the most important, is now at our disposal. While the infections conveyed in fluids or solids are less numerous and have fewer victims, the diseases carried by the air are very many, and the list is constantly growing. Tuberculosis, scarlet fever, measles, pertussis, chickenpox, variola, influenza, pneumonia of various kinds, diphtheria, epidemic cerebrospinal meningitis, acute poliomyelitis, acute articular rheumatism, pyogenic bacterial infections, arteriosclerosis, acute nephritis, typhoid fever, etc., are now known to be air borne infectious diseases. Where do these infections gain entrance to the body? Probably at the spot where the first signs of disease are detected, namely, in the nasopharynx. It has been proved beyond the shadow of a doubt that this is the road of infection in the majority of the diseases that have been named. Note the chronicity of the symptoms, primary local infection and later toxæmia, and the sequence of local and general bacterial find-

ings. Some of the best understood of the diseases which show these relations clearly are influenza, scarlet fever, epidemic cerebrospinal meningitis, acute articular rheumatism, and diphtheria.

#### 1. Pregnancy in Its Relation to Disease.—

French, in the first of his Goulstonian lectures, states that there are certain medical diseases for which pregnancy itself seems directly responsible. One of the most definite of these is herpes gestationis, a disease apparently related to pemphigus, hydroa, erythema bullosum, and to dermatitis herpetiformis. The eruption varies as to the relative preponderance of erythema, papules, and wheals, but the distinctive lesion is vesicular or bullous. The vesicles are not often confluent or crowded together as in herpes zoster. They are preceded by an itching erythema, rapidly becoming papular and then vesicular. The chief clinical distinction between it and dermatitis herpetiformis is the direct relationship of herpes gestationis to pregnancy. Increased pigmentation of the skin is apt to be left after each attack; this may be generalized all over the body, but usually it is most marked where the eruption has been the worst. It is probably not allied in any way to uterine chloasma, and the chief causes are the constant scratching and rubbing, and also the arsenic which is given in most cases. Herpes gestationis agrees with the other bullous dermatoses in exhibiting eosinophilia; this is not confined to the blood alone, but the eosinophile leucocytes are also found in the interepithelial lymphatic spaces, and in the fluid of the blebs. But they are not increased in the fluid of an artificial blister. The general opinion is that the eosinophilia is the result of the skin lesion, due, perhaps, to the absorption of something from the skin, just as in ankylostomiasis there is eosinophilia, due to absorption of a toxine from the bowel. It seems clear that the cause of herpes gestationis arises within the body, and that the lesion is not due to agents acting directly upon the skin from without. Bacteriological investigations have proved negative. Impetigo herpetiformis seems to be a virulent degree of herpes gestationis, dangerous to life. Fortunately, it is rare. The eruption is pustular, and may spread over the entire body. The pustules dry up with the formation of scabby crusts, fresh ones appear in the adjacent skin, and so the eruption spreads in a circinate manner. There is no ulceration. The patient has continuous remittent fever, with an exacerbation with

each fresh crop of pustules. Vomiting and delirium are usual, and the patient generally dies in a few months. Labor does not prevent the fatal termination. Post mortem there is no evidence of pyæmic or septicæmic infection. The cause is probably an internal toxæmia. Eczema and psoriasis are often influenced by pregnancy. As a general rule, a patient's eczema will very likely be mitigated rather than made worse during pregnancy. Pregnancy either makes psoriasis worse or better—more often the latter. On the other hand, the effect of lactation upon psoriasis is almost invariably bad. Pregnancy is an important factor in the causation of pyelonephritis. The sequence of events probably is as follows: Enlargement of the uterus; compression of the ureter against the brim of the true pelvis; consequent difficulty in the ejection of urine secreted by the corresponding kidney; infection of the urine retained in the partially obstructed ureter and renal pelvis; and subsequent spread of the kidney substance itself. And just as in pyelonephritis in man, due to prostatic enlargement, removal of the obstruction by the birth of the child tends to cure the renal mischief. In nearly every case the right kidney is very much more affected than the left. This is probably due to the fact that the uterus develops much more to the right than to the left; it also inclines and is rotated to the right. The bacteriology of the condition is very constant; in all but a few of the cases the *Bacillus coli communis* is the causative microorganism. It is nearly always in pure culture. The pyelonephritis of pregnancy is often mistaken for something else—*e. g.*, lumbago, influenza, pneumonia, pleurisy, appendicitis, etc. The main symptoms are backache and pyrexia, with or without headache, vomiting, or rigors. Examination of the urine will, of course, show pus and microorganisms.

**3. Excision of the Rectum for Cancer.**—Morton's article is based on a series of thirty-four consecutive cases of rectal cancer treated by excision. There were four deaths, a mortality of twelve per cent. Two deaths were due to shock, one to peritonitis, and one to acute mania. Eight cases have remained free from recurrence after one to three years. In all the recurrent cases the disease was extensive. In fifteen cases the coccyx was not removed, and the peritonæum was not opened. Where the growth is low down, yet far enough above the anus to leave a healthy segment of bowel, by removing the coccyx a circular union can be made, sphincter action preserved, and yet the peritoneal cavity not have to be opened at all. It is usually stated that if the growth is fixed to the tissues outside the rectum the case is inoperable. But this does not hold good always. Growths may be fixed to the prostate and yet not infiltrate it. Fixation to the lower end of the sacrum or the coccyx need not contraindicate operation, for that portion of the bone can be removed. If the posterior vaginal wall is involved, it can also be removed. As a rule, there is no great amount of shock after the operation. If it is done with the patient almost prone, very little blood is lost. The best position for drainage is on the back. But pressure must be taken off the wound by proper arrangement of the pillows. After the first twenty-four hours the back and

lateral positions should be alternated. As regards the amount of control over evacuation of the bowel after the operation, the result is generally about the same as after a colotomy on the left side. The bowels act once or twice a day, and leaking is slight or absent. After circular union the action of the bowels may be normal. Half the patients here reported were from sixty to seventy years of age. In two very extensive cases the ages were only twenty-six and twenty-eight years. In conclusion, the author's study of these thirty-four cases shows that, even including the cases of growth high up, the excision of which necessitates removal of a part of the sacrum and a free opening of the peritoneal cavity, the mortality is not very high. There may be no recurrence in quite a number of the cases, and life will be much prolonged and made much more comfortable in a large number.

# LANCET.

May 2, 1908.

1. The Influence of Pregnancy upon Certain Medical Diseases, and of Certain Medical Diseases upon Pregnancy (Goulstonian Lectures, I). By H. FRENCH.
  2. The Special Psychology of Women. By T. C. SHAW.
  3. Ophthalmia Neonatorum; an Experiment in Treatment. By A. N. WALKER and A. A. MUSSEN.
  4. The Treatment of Trachomatous Dacryocystitis. By T. H. BUTLER.
  5. On the Pathology and Treatment of Inguinal Hernia in Children. By C. H. FAGGE.
  6. Disseminated Sclerosis, commencing with Failure of Vision. By R. T. WILLIAMSON.
  7. On the Rectal Administration of Antitoxic Sera. By J. P. PARKINSON.
  8. Motoring Notes. By C. T. W. HIRSCH.
- 3. Ophthalmia Neonatorum.**—Walker calls attention to the unsatisfactory results of treatment of cases of ophthalmia neonatorum among the poor, due to the cases being seen late and not being continuously treated. He is satisfied that the disease is very amenable to treatment if attacked vigorously at the outset. But this is the very treatment which the average case does not receive, owing to the impossibility of carrying out, in the homes of the poor, frequent and thorough irrigation both by day and by night. The indication then is the admission of cases occurring among the poor, as soon as possible after the beginning of the disease, into an ophthalmic hospital, where vigorous treatment can be carried out. A separate ward must be provided and a special nurse appointed who must not be allowed to touch clean cases. In order not to interfere with the feeding and nutrition of the infant, its mother should be admitted to the hospital also.
- 5. Inguinal Hernia in Children.**—Fagge accepts the view of Russell that hernia is primarily a developmental defect owing to either partial or complete persistence of the embryonal processus vaginalis. As regards the diagnosis of inguinal hernia in children, the only other inguinoscrotal swelling likely to cause difficulty is a patent processus vaginalis containing fluid—a "congenital" hydrocele. This is usually irreducible, though the fluid spontaneously returns to the abdomen after the child has been lying down for a short time. When the fluid returns into the vaginal process it does so slowly, and this is in itself quite sufficient to distinguish it from a hernia. As regards treatment, the author has never seen circumstances have

the slightest effect, either in aiding the cure or even in preventing the enlargement of a hernia. The woolen skein is absolute as a truss. When truss treatment is adopted it must begin as soon as the rupture appears. A well fitting spring truss covered with rubber must be applied daily before the child is lifted from its cot, while the hernial contents are still within the abdomen. In many cases where the hernia tends to come down at night a light truss must be worn at night also. The difficulty of efficiently carrying out this line of procedure is enormous. A truss must be worn for several years before we can hope that the hernia will not return if it is omitted, and during this time attention must be paid to changing the truss in accordance with the growth of the child. The writer thinks it is the duty of every medical man to impress upon parents that trusses hold out no prospect of permanent cure, and that the time has certainly arrived when cure can be more easily and almost certainly obtained by operative means, which, in themselves, are practically devoid of risk. The following are absolute indications for operation. 1. Herniæ which cannot be kept up by trusses, or which are painful when a truss is worn. 2. Large scrotal herniæ which have stretched the inguinal canal considerably and therefore render trusses necessary throughout life. 3. The association of an undescended testis with an inguinal hernia. 4. A hernia which has been irreducible on a previous occasion. This does not, of course, include strangulated herniæ, which must be dealt with at once. In the writer's opinion, taxis should never be attempted.

6. **Disseminated Sclerosis.**—Williamson reports a series of cases of disseminated sclerosis in which failure of vision, in one or both eyes, was the first symptom of the disease. Other symptoms may not appear or may be very slight for a long period, even for many years. Signs of optic atrophy may or may not be present. At first these cases are usually diagnosed as primary optic atrophy, or as retrobulbar neuritis of "unknown origin." In this form of disseminated sclerosis, pain, and anæsthesia are very rare. The signs of chief diagnostic value in the early stage are: (1) Unilateral or bilateral visual failure, with central scotoma in some cases, and often with pallor of the optic disc, especially of the temporal half; (2) the Babinski type of plantar reflex on one or both sides; (3) the irregular and shaky character of the handwriting, even when the tremor is so slight that it can hardly be detected; and (4) the age of the patient, under forty years. The absence of any cause for the affection and of any history of syphilis, the absence of any pain and anæsthesia, and the presence of the knee jerks, tendo Achillis reflexes, and pupillary reflexes are points of diagnostic value in favor of disseminated sclerosis. In many cases, after the visual defect has become marked there is a decided improvement or almost complete recovery of vision. Even when the visual defect does progress it rarely advances to complete blindness, differing in this respect from the optic atrophy of tabes dorsalis. Though the prognosis of disseminated sclerosis is usually unfavorable and the termination fatal, yet in many cases the disease is very chronic.

## LA PRESSE MEDICALE

April 11, 1908.

1. The Suture of Vessels, By ALBERT FROUIN.
2. Facial Hemispasm, with Motor Troubles of the Limbs of the Opposite Side, By BRISSAUD and J. A. SICARD.
3. The *Treponema Pallidum*. Diagnosis of Syphilis with the Ultramicroscope, By PAUL GASTOU.
4. The Midday Diarrhœa, By R. ROMME.

1. **The Suture of Vessels.**—Frouin describes with illustrations the technique of uniting the ends of a divided artery, and of joining an artery and a vein.

2. **Facial Hemispasm with Motor Troubles of the Limbs of the Opposite Side.**—Brissaud and Sicard report three cases. The first, a man forty-six years old, syphilitic, with facial hemispasm on the right side, hemiparesis of the upper and lower limbs of the left side, and a facial paralysis on the left side of a peripheric type; the second, a general paralytic, fifty-two years of age, who had total facial hemispasm of the right side, ten to twenty spasms an hour, with hemiparesis of the upper and lower limbs; the third, a tabetic, of forty-eight years, with left facial hemispasm and hemiparesis, and trembling of the right upper and lower limbs.

3. **Diagnosis of Syphilis with the Ultramicroscope.**—Gastou describes the principle of the ultramicroscope, the mechanism of the Leitz-Cogit instrument, the manner in which it is used, and the appearance of the *Treponema pallidum* when thus seen. Finally, he gives a distinctive diagnosis between the spirochæta and spirillæ as seen with the ultramicroscope.

1. The Treatment of Phlegmon of the Sheath of a Tendon, By R. KLAPP.
2. Concerning Special Nervous Symptoms in Addison's Disease, By L. WAGNER.
3. Wassermann's Syphilis Reaction, By R. BENEKE.
4. Concerning the Rôle of the Lipoid in Wassermann's Syphilis Reaction, By O. PORGES and GEORG MEIER.
5. The Pathogenesis of Salivation, By H. RÖDER.
6. The Symptomatology of Chorionepithelioma, Particularly of the Pulmonary Metastases, By E. SCHEIDEMANDEL.
7. The Indications Discoverable with the X Rays of Gastrectasia and Ptosis of the Pylorus, By FRANZ M. GRÖDEL.
8. Concerning Myosis in Reflex Immobility of the Pupil, By LEVINSON.
9. Concerning Sigmoiditis and Perisigmoiditis Puerperalis, By F. LEHMANN.
10. Concerning a Hitherto Undescribed Symptom Observed in Chronic Strictures of the Œsophagus, By P. M. REWIDZOFF.
11. The Leuchæmic and Pseudoleuchæmic Diseases of the Skin, By ARTHUR ALEXANDER.

1. **Treatment of Phlegmon of the Sheath of a Tendon.**—Klapp incises the phlegmon not from

the flexor side, but always from the lateral side. In the fingers the incisions are made on either side to the palmar side of the arteries, so that there is no danger of wounding them, leaving a portion of the skin unwounded at each joint. By these incisions the pus is freely evacuated and the sheaths are then washed out with a warm physiological salt solution. A dressing is then applied and changed daily. He has used this method in nineteen cases which he divides into four groups: 1, Ten cases of pure phlegmon of the sheath of a tendon, nine cured, one became partially necrotic. 2, Two cases with large subcutaneous panaritium over the tendon in which the latter had been exposed for a long time through extensive necrosis of the skin, one cured, one partly necrotic. 3, Six cases of panaritium tendinosum complicated with changes in the bones (infected fracture of the phalanx by a bite, gunshot injury with laceration of the sheath of the tendon, panaritium ossale), two cured, four partially or wholly necrotic. 4, One case which resulted in death from sepsis on the twelfth day after the infection, in spite of the most careful evacuation of the pus.

**4. The rôle of the Lipoid in Wassermann's Syphilis Reaction.**—Porges and Meier say that it is certain that the materials demonstrated in the serum and other body fluids by Wassermann's reaction should not be designated as antibodies in the sense in which that term has hitherto been used, i. e., to denote substances connected with the healing process. They are rather materials which possess a great power of elimination of certain lipid substances of exceeding importance to the normal cells of the organism, particularly of lecithin. While they state that it is their desire not to draw conclusions, but rather to simply report experimental facts, they nevertheless point out that further conclusions might be drawn from the knowledge thus discovered in regard to the details in syphilitic infection and in postsyphilitic diseases, especially as literature already contains a great number of facts and observations which indicate the rôle played by lecithin in certain syphilitic affections.

**5. Pathogenesis of Salivation.**—Röder concludes from the results of his experiments on dogs that the salivary secretion is affected by three different kinds of reflexes: 1, the involuntary reflexes of the oral cavity; 2, the voluntary reflexes; 3, the reaction from the sensory motor zone of the cerebral cortex when simultaneous movements are executed.

**6. Chorionepithelioma.**—Scheidemandel says that the chorionepithelioma is the form of tumor which is most frequently productive of pulmonary metastases. The symptoms are sudden hæmoptysis, dyspnoea, cyanosis, chills, and pain in the breast, which form the first and only indications of the presence of this form of tumor in persons previously with healthy lungs. The history of the former existence of a hydatid or cystic mole is of great importance in the diagnosis. Further confirmation can be obtained from a gynecological examination, especially an inspection of the vagina for the varicose tumor nodules. In men chorionepithelioma of the lungs may appear in association with teratoid neoplasms of the testicle. Treatment must be operative

with demonstrable disease of the uterus; the presence of pulmonary metastases does not form a contraindication to the operative procedure.

**7. Indications Discoverable with the X Rays of Gastrectasia and Ptoxis of the Pylorus.**—Grödel delineates the conditions in a number of patients examined by him and compares them with the delineation of the picture presented by the normal stomach. The pathological conditions were those of atonic ectasia and hereditary ectasia of the stomach, with or without ptoxis of the pylorus.

12. Eye Disease Caused by Working with an Artificial Fertilizer, By BOND.
13. Concerning a Rare Case of Extensive Destruction of Bone Resulting from a Tuberculous Suppuration of the Middle Ear in a Child Two Years of Age, By MÜHLENKAMP.
14. A Clamp for the Umbilical Cord, By MÜLLER.
15. Obituary of Friedrich von Esmerich, By WAITZ.

**2. Practical Value of the Opsonic Index.**—Saathoff concludes that on account of the complicated nature and extremely difficult technique, the method of determination of the opsonic index can be practised only in certain institutes which are able to employ an investigator for this purpose. This detracts greatly from the value of the method. On account of the great and incalculable sources of error which appertain to the determination of the opsonic index the method is of value only in the rare cases in which the eruptions are very great. For these reasons the opsonic index is unreliable for therapeutic application. The value and the further development of active immunization remains untouched.

**4. Treatment of Surgical Tuberculosis with the Antituberculous Serum of Marmorek.**—Hohmeier states as the result of his experience that he has not observed any serious disturbance or injury of the organism from the use of the serum, that he considers it possible that in very mild cases of bony tuberculosis Marmorek's serum may accelerate a cure, but cannot ascribe a positive effect upon quite fresh and slight tuberculous diseases of the bones or joints to the serum; that he thinks he has observed an effect of the serum upon granulations which, before the treatment, were gray and sluggish, and afterward assumed a bright red appearance, that he did not obtain a cure in cases of tuberculosis of the bones of moderate severity, though in one case he

succeeded in closing obstinate fistule; that in severe cases of tuberculosis of the bones he did not observe the least improvement as the result of the serum, either immediately or, so far as he had opportunity to observe, subsequently, and that he did not obtain an improvement of the general condition which he could ascribe to the serum.

**6. Serum Reaction in Scarlet Fever and Measles.**—Schereschewsky says that, although no definite conclusions in regard to the relations of the streptococcus to scarlet fever can be drawn from his experiments, yet the latter show the presence of materials in the serum of scarlet fever patients which have the power to precipitate each other, and that these substances, scarlet fever precipitin and precipitogen, are not to be replaced by the streptococcus precipitinogen of the streptococcus pyogenes of his stock.

**10. Intermittent Lameness.**—Grube reports four typical cases of dysbasia angiosclerotica with absence of the foot pulse. All the patients were men, aged sixty-six, fifty-four, seventy, and fifty-nine. Three were suffering from diabetes or glycosuria, one had contracted kidneys. Erb ascribes a certain aetiological value to the misuse of tobacco, and this had formerly been present in two of the cases. One case gave no history of the misuse of either alcohol or tobacco, or of syphilis.

with Especial Reference to Whitman's Method,  
By C. N. COWDEN.

**1. A Point in the Technique of Appendicectomy.**—Lilienthal remarks that the handling of the intestines, and even their exposure to the air, is one of the most potent causes of shock after abdominal operations. To lessen this element of danger in appendicectomy, he has used the following method, which can be performed in most of the cases, especially in interval cases and in the early stage of the acute form of perityphlitis. Through a small incision made in the locality preferred by the operator, a gloved finger is inserted, locating the cæcum; a portion of this viscus is withdrawn with dressing forceps, and landmarks followed in the usual way

to locate the base of the appendix. During this procedure there will be a little unavoidable handling of intestine outside of the abdomen. Having exposed the base of the appendix, a ligature is passed through the mesentericolum, to be used subsequently for ligating the organ; the ends of this ligature are left long, and are tied together or held with a clamp. The exposed part of the appendix and all other intestines are now returned to the abdominal cavity. When traction upon the ligature is made the base of the appendix and nothing more is brought into the wound. In the majority of cases it will then be found extremely simple to deliver the entire appendix even though a considerable number of adhesions should be encountered. During the procedure of freeing and removing the appendix, this organ only is in the field.

By R. LAKE.

#### 2. Polycythæmia in Diseases of the Heart and Lungs and During Residence in High Altitudes.

—West observes that an abnormal number of red corpuscles may be absolute or relative. The latter is due to concentration of the blood, as from choleraic diarrhoea; the former is due to an actual increase in the volume of blood in the body. Cases of the former may be due (1) to imperfect oxygenation of the blood and tissues resulting from circulatory disturbance in chronic cardiac and pulmonary disease, or (2) to residence at a high altitude, with diminished oxygen tension in the inspired air, or (3) to splenomegalia. In the first class of these cases, deficiency of oxygen stimulates the function of the red bone marrow and causes increased production of red cells, being thus a conservative or compensatory reaction. In the second class there is also a conservative vital reaction of the bone marrow, compensating for the difficulty in oxygenation at the high altitudes. In the third class nothing further is known than that here also is an increased activity of the bone marrow. True polycythæmia is usually associated with a condition of true plethora. The viscosity of the blood is increased in all of the varieties of polycythæmia, and this is a factor of importance in chronic disease of the heart and lungs. It is an indication for venesection, with consequent relief to the right side of the heart and dilution of the blood current.

#### 3. Injuries to the Head in Young Children.—

Drew states that these injuries differ from similar

ones received in later years, the skull being less resisting, the bones flexible, the dura more adherent, and the sutures ununited. Fractures rarely occur, but may result from abnormality in the maternal pelvis, precipitate labor, or the use of forceps. Depressions may be slight, with indentation which gradually disappears, or they may be extensive and demand operation. The depression may destroy life in utero, or such a result may be deferred for hours or days after birth. Injury to the brain may be quite out of proportion to the apparent injury to the skull. If the dura is torn the subdural space will be opened, the cerebrospinal fluid will escape, and a cephalohydrocele may result. If such a tumor increases in size the prognosis will be unfavorable, meningitis or hydrocephalus being the probable sequence. The most frequent injury to the head in the newborn is hæmatoma. If unassociated with fracture it is usually absorbed in three or four weeks. In fracture, with or without depression, the question of operation becomes an important one for consideration.

**4. The Importance of Accurate Diagnosis and the Treatment of Fractures in the Vicinity of Joints.**—Fagge justly remarks that immediately after a fracture a correct diagnosis is often impossible. The diminished mobility often suggests dislocation, especially in those fractures which extend from a joint surface into the shaft of a bone. Even radiography may not reveal such lesions. It must not be forgotten that dislocation is frequently associated with fractures. Following Cheyne, these fractures are of three forms. 1. Those which do not involve the articular ends of the bone and are outside the capsule. 2. Those which extend into the joint cavity, as a linear split involving one of the condyles of the humerus or a T shaped fracture or comminution of the articular extremity. 3. Those which do not extend into joints, but are typically associated with displacement of the adjacent articular surfaces. A diagnosis may be confirmed by radiography, but one must be able to make a diagnosis without such aid. The deformity should be reduced under a general anaesthetic, and an x ray picture may be taken after the application of the splint. If the fragments do not remain in apposition an open operation will be required within five or ten days from the reception of the injury. The aim of treatment should be not only the replacement of the normal outline of the bone, but restoration of the movements of the adjacent joint and muscles.

**6. Some Important Points in Connection with Infant Feeding.**—Burnet assumes that there is no perfect substitute for mother's milk. Diluted cow's milk is the best substitute there is, but the tendency is to make the dilution too complicated. Sterilized milk is dangerous. A child may gain in weight under its use, but soon it will become anæmic, constipated, and perhaps rachitic. Milk deposits should not be managed by nurses and women, but by a physician who knows the supreme value of breast feeding. Sterilized milk, after repeated handling, is no longer sterile, and that is the condition with much of the supply in milk depots. Pure cow's milk is not more likely to cause diarrhoea than the average breast milk. Sterilized milk, it must be remembered, has been deprived of some

of its most useful properties. As to the matter of weight in infants, too much stress has been laid upon this subject. Gain in weight does not necessarily indicate gain in health and strength; it may even be associated with rachitis. Loss of weight, however, does indicate retrogression. Infant foods are not essential to the rearing of healthy children.

**7. Chronic Colitis and Its Surgical Treatment.**—Mummery classifies this disease as chronic mucous colitis, membranous colitis, chronic ulcerative colitis, and follicular ulcerative colitis. The electric sigmoidoscope has greatly extended our knowledge of this disease, for the sigmoid is the portion of the colon most frequently affected. The first two of these forms are quite similar; their cause must be discovered, and if this should be appendicitis, cancer, or local lesion, the cause must be removed surgically. One of the suggested measures of treatment is appendicostomy, after which the colon can be regularly washed out with appropriate solutions. Another suggestion is ileosigmoidostomy, by which the ileum is drained directly into the rectum. Chronic ulcerative and follicular ulcerative colitis are also two forms of the same disease, the ulcers being small and punched out, with red, raised edges; diarrhoea and bloody stools are usually present. Or the ulcers may be large, irregular, and extend around the bowel, the condition being serious and often fatal. Medical treatment having failed in such cases, a right lumbar colotomy should be performed. This will often turn the scale in the patient's favor.

7. The Pathology of Tuberculosis in Children. By J. McCRAE.
8. Laboratory Aids to the Diagnosis of Tuberculosis in Infants. By T. H. COFFIN.
9. Channels of Communication in Tuberculosis. By S. McC. HAMILL.

**2. The Need of Greater Accuracy in Prescribing Starch in Infant Feeding.**—Ladd states that his plea is neither for nor against the use of starches in the first year of life, but for a more scientific basis of administering them when they may be needed. Starch should be prescribed in percentages, the same as fats, sugar, and proteid. Infants being unable to digest starch at birth, the logical way of using it, barley water, for example, is to begin with a small percentage and gradually increase it. In a series of analyses of cereal decoctions it was observed: (1) That the barley used was preparation made after the manner described have the same composition. (2) That two ounces of either flour to a quart gave a 3 per cent. starch solution. (3) That three ounces of either flour to a quart give 4.5 per cent. starch solution. (4) That the percentage of fat added to a mixture by the cereal is

practically nothing. (5) That the percentage of proteids added to a mixture by the cereal is small. The general formula for the cereal decoction to be added to modified milk to obtain any percentage of starch is starch percentage desired, multiplied by total ounces mixture and divided by 3.5.

**6. Sarcoma of the Kidney in Infancy.**—Cheney is presented with three questions in the study of this subject: (1) How frequent is sarcoma of the kidney in infancy? The answer is it is exceedingly rare. (2) How are we to recognize so rare a disease when confronted with it? The answer is that it is a tumor of very rapid growth, that it does not cause cachexia until it is very large, that it causes little or no pain or disturbance of the general health, and that it is usually first discovered by accident on account of change in the contour of the abdomen. Hematuria may or may not be present. Such tumors lie behind the colon; they begin at one side, but grow downward and inward, other abdominal tumors being more centrally located from the start. Such tumors are also hard, firm, and fixed. (3) Is operation justifiable? The mortality from operation is high, and recurrence is not infrequent, but as it is the only treatment which offers a shadow of hope, it is the treatment which the author advises.

**9. Channels of Communication in Tuberculosis.**—Hamill draws the following conclusions: 1. That it is impossible to gain knowledge concerning the point of entrance either from the location or the degree of the tuberculous lesions. 2. Foetal infection has been proved, but is not common. 3. Infection through the mouth, tonsils, and pharynx is frequent, and may be produced by inhalation or ingestion. 4. Primary inhalation infection through the lungs does occur. 5. Infection through the intestinal tract is definitely proved. 6. The bronchial glands and lungs may be infected through the intestinal tract as well as through the lower respiratory tract. 7. The relative significance of the various modes of infection is difficult to determine, for it has been clearly shown that from whatever point the tubercle bacilli may be introduced they may eventually reach the bronchial glands and lungs without leaving any evidence as to the mode of entrance.

## Proceedings of Societies.

### NEW YORK ACADEMY OF MEDICINE.

*Meeting of February 20, 1908.*

Dr. ABRAHAM JACOBI, Chairman pro tem.

*The meeting was held under the auspices of the Section in Neurology and Psychopathology.*

**The Development of the Modern Care and Treatment of the Insane, as Illustrated by the State Hospital System of New York.**—Dr. CARLOS F. MACDONALD read this paper. He said he had entered upon the work of caring for the insane in 1870. Since that time he had witnessed and participated in the efforts made to improve the methods of caring for the insane, especially as regarded the disuse of mechanical restraints and punish-

ments of various kinds, and the abolition of the barbarous system of so called "county care" and the substitution thereof of the modern hospital for the insane. Cupidity and self interest should have no sway where suffering humanity was concerned. Insanity, of all diseases, was by far the most frequent, most widely prevalent, and most far reaching in its effects, and the commonwealth was in duty bound to provide these dependent sufferers with suitable shelter, food, and raiment, together with means of occupation and diversion, competent medical care, and supervision. To-day in the State of New York alone there were more than 29,000 certified lunatics, not to mention the large number of border line cases which were at any time likely to require medical care and attention. The average life of the insane was twelve years, and the annual per capita cost of maintenance was \$200; therefore, each person who failed to recover during this period represented a loss to the State of \$2,400; whereas a sane person for a like period would represent a gain of \$2,400. To-day there were in the State of New York fifteen State hospitals for the insane (two for insane criminals) and twenty-two licensed private institutions for the insane. The whole number of committed insane in the public and private hospitals of the State at the end of the fiscal year, September 30, 1907, was 29,093 (13,927 men and 15,166 women). The whole number of insane in licensed private institutions was 777. The net increase for the fiscal year in all institutions was 791; in the State hospitals, including the criminal asylums, the net increase was 799. The number of resident medical officers in State hospitals was about 150, and attendants, nurses, and other employees, 5,000. The cost of the State hospitals represented an investment of more than \$26,000,000, while the average annual expenditure for their maintenance was about \$5,000,000. The average weekly per capita cost of maintenance for the last fiscal year was \$3.53. This weekly rate was somewhat higher than the average for the whole United States, in which the number of insane was roughly estimated at 200,000. The first attempt on the part of the State to provide State care for her insane was made nearly sixty years ago, when, in 1836, the legislature created the State Lunatic Asylum at Utica, now the Utica State Hospital. This institution, however, was not opened for the reception of patients until January, 1843. Prior to that time the insane poor, in both acute and chronic cases, were mostly cared for in county or town poorhouses or in jails. Provision was made whereby patients who failed to recover after a certain length of time, or who were pronounced incurable, might be removed to the county poorhouse. This was a most inhumane provision, and it continued in operation, with certain modifications, though with practically the same results, until the creation of the State Commission in Lunacy, in 1880, and the subsequent passage of the State Care Act in 1890. The standard of care and the resultant conditions were graphically portrayed in the following extract from a report made to the legislature in 1864 by the late Dr. Sylvester D. Willard, who personally investigated the condition of the insane in the various poorhouses,

county insane asylums, and other institutions where the insane poor were kept:

In some of these buildings the insane are kept in cages and cells, dark and prisonlike, as if they were convicts, instead of the life weary, deprived of reason. They are in numerous instances left to sleep on straw, like animals, without other bedding, and there are scores who endure the piercing cold and frost of winter without either shoes or stockings being provided for them; they are pauper lunatics and shut out from the charity of the world, where they could at least beg shoes. Insane, in a narrow cell, perhaps without clothing, sleeping on straw or in a bunk receiving air and light only through a rough, prisonlike door, bereft of sympathy and of social life, except it be with a fellow lunatic, without a cheering influence or a bright hope of the future! The violent have only to rave and become more violent, and pace in madness their miserable apartments. These institutions afford no possible means for the various grades of the insane; the old and the young, the timid and the brazen, the sick, the feeble, and the violent, are herded together without distinction as to the character or degree of their madness, and the natural tendency is for all to become irretrievably worse. In some violent cases the clothing is torn and strewn about the apartments, and the lunatics continue to exist in wretched nakedness, having no clothing and sleeping upon straw filthy with excrement and unchanged for several days. Can any picture be more dismal? And yet it is not overdrawn.

The publication of the report aroused public sentiment and resulted in a second spasmodic effort to provide for State care of the chronic insane by the establishment, in 1865, of the Willard Asylum for the Chronic Insane, now the Willard State Hospital, and subsequently an institution at Binghamton. This second era in lunacy legislation for State care largely failed of its object through delay on the part of the State to provide sufficient accommodations for this class; owing to this lack of accommodation, the State asylums for the acute insane were permitted by law to continue the pernicious practice of returning their unrecovered patients to the county poorhouses, some of which were called "county asylums." This inhuman practice continued until the creation of the State Commission in Lunacy, in 1889, and the enactment of the State Care Law in 1890. This commission, the creation of which gave a powerful impetus to the State care movement, promptly joined hands with the State Charities Aid Association and others in their efforts in behalf of State care. In the first year of its existence (1889) it made a thorough examination of the twenty-one county institutions for the insane, in many of which the conditions were found to be nearly as bad as those portrayed in Dr. Willard's report. In its first report to the legislature the commission disclosed the wretched condition of these institutions and their inmates, and recommended the abolition of the county care system and the transfer of all the inmates of such institutions to State hospitals. This report gave the death blow to county care of the insane in the State of New York. Dr. MacDonald then called attention to the important features of the State Care Act (Chap. 126, Laws of 1890) and of the acts supplementary thereto.

Among the more important improvements that had accrued for the insane and their government, under the new order of things, might be mentioned the following: 1. A codification of the laws of the State relative to the insane into one comprehensive statute, known as the Insanity Law. 2. A complete registration of all qualified examiners in lunacy. 3. A complete registration of all persons committed

to institutions for the insane, both public and private. 4. Provision for the transfer of patients from one institution to another without recommitment. 5. The removal of patients from their homes or elsewhere, by trained nurses sent from the hospitals and, if necessary, a medical officer. 6. Removal of the legal distinction between acute and chronic insanity by designating each State institution for the insane as "hospital" instead of "asylum," and inculcating the hospital idea. 7. A regulation regarding the correspondence of the insane, which provided that any patient who desired might write at least once in two weeks, etc. 8. Provision for paroling patients for a period of thirty days, with a return to the hospital without recommitment. 9. A regulation requiring that patients on admission shall be informed of the nature of the institution. 10. Affording to all patients the legal right of a hearing. 11. A rule restricting the issuing of licenses to conduct private establishments for the insane to reputable physicians. 12. A general adoption of a uniform dress for nurses' and attendants' wear. 13. Provision for the clinical teaching of psychiatry in the State hospitals. 14. Provision for the appointment of medical internes in addition to the regular medical staff. 15. A regulation requiring competitive civil service examinations for appointments as resident officers. 16. A material increase in the average rates of salaries and wages of all grades of service. 17. The introduction of women nurses in the men's wards. 18. A material extension of accommodations for attendants and nurses in detached buildings. 19. The establishment of training schools for nurses in all the hospitals. 20. Provision for the employment of dentists for patients, also for ophthalmological examinations by eye specialists. 21. An annual allowance to each hospital for the purchase of medical books and journals and other periodicals. 22. The employment of a chef in each hospital. 23. The adoption of a schedule of food supplies. 24. A marked improvement in the methods of bathing. 25. A requirement that the hospitals shall enter into joint contracts for the purchase of staple articles of supply through competitive bids. 26. The abolition of mechanical restraints in all the hospitals, and the substitution thereof of useful occupations, diversions, and amusements of various kinds. 27. The introduction, in 1901, of tent life for the care of the tuberculous patients. Dr. Mabon, superintendent of the Manhattan State Hospital on Ward's Island, stated that the recovery rate of patients cared for in the open air was as high as forty per cent., whereas the death rate was "extremely low." 28. The systematic employment of patients at useful occupations. 29. The establishment of a pathological institute. Prior to October 1, 1893, at which time the commission was given supervision and control of the hospital finances, the average annual per capita cost of maintenance was \$222; the commission reduced this to \$184, and at the same time materially raised the standard of care, thus effecting, in a single year, a saving of hundreds of thousands of dollars.

Dr. WILLIAM MABON, superintendent of the Manhattan State Hospital, called attention to the institute work and to the uniform methods of clinical study and laboratory research. The methods now

used at the Manhattan State Hospital were as follows: The division for men, as well as that for women, had a reception service; in each there was a staff of from four to five physicians who worked under the direction of an assistant. Physical examinations were made at first; afterward the mental symptoms were studied. Dr. Adolf Meyer was the director of the pathological institute, and he had formulated a very valuable classification. Meetings of the staff were held in the two divisions each week day morning to give them an opportunity to express an opinion as to the advisability of discharging a patient, etc. Every third Tuesday night was held a staff meeting, and original papers were presented and discussed. The results of this method had shown the great value to be obtained by members of the staff.

Dr. FREDERICK PETERSON, ex-president of the New York State Commission in Lunacy, said that a book might be filled with praise for what they had accomplished; they could also fill a book with what they had not accomplished. Nearly twenty per cent. of the insane owed their insanity to a preventable cause, alcohol; through alcoholic insanity there was a loss to the State of about \$2,400,000. People should be taught that insanity was a preventable and curable illness. Insanity was a disease; an insane person was sick. The responsibility of overcrowding, which the Lunacy Commission reported, was due to neglect by the legislature; only one hospital for the insane had been built in eighteen years. On October 1, 1906, the Lunacy Commission reported that the excess of patients in the hospitals over the estimated capacity was 1,812; more money should be appropriated for the building of more asylums. It was an interesting fact that the admissions of people between sixty and one hundred years old amounted to some sixteen per cent. to seventeen per cent., physiologically senile or dotards. There was also an inadequate supply of physicians; the proportion should be not less than one physician to 150 patients.

Dr. CHARLES W. PILGRIM, of Poughkeepsie, president of the State Commission in Lunacy, told of the many obstacles the commission had to overcome, and believed that when the history of the insane in the State of New York was written, two names would appear very prominently, those of Dr. Carlos F. MacDonald and the Hon. Goodwin Brown.

Dr. ALBERT WARREN FERRIS, member of the New York State Commission in Lunacy, said that licensed private houses for the care and treatment of the insane were allowed to receive voluntary patients, as well as those committed under the Insanity Act, a very reprehensible condition. No actual ruling as to these voluntary patients was made until 1891, when the new commission formulated a special document. Attention was called to Section 445 of the Penal Code, under the title Maintaining Private Insane Asylums, and to Section 47 of the Insanity Law, and the amended chapter 497, Laws of 1905. There seemed to be a desire among a certain class of physicians to quietly and secretly place patients in the custody of unskilled and improper persons. The question as to when a patient was properly a voluntary one was a vexed one, but

he believed such a person to be one who understood to some extent his ailment in so far that he knew he was ill, and also understood that the house to which he was taken was for the treatment of ailing people and that he was willing to stay. Voluntary patients should have every possible facility to prevent the graver forms of mental disturbance. Efforts that were now being made to prevent insanity by studying conditions, food, occupations, education, environment, etc., would lead to the saving of many valuable lives, as well as to the early restoration of many hundreds of shattered individuals to their position in the community, to enjoy life, liberty, and the pursuit of happiness.

The Hon. GOODWIN BROWN said that up to 1880 the world for the insane was in chaos; they lived to be cured by chance, or else were treated as criminals. Efforts made to alleviate the condition of these unfortunates were futile. In all great crises men were brought forth when most needed, such as Hannibal, Caesar, Cromwell, and Napoleon, and in this crisis the man most needed was forthcoming, Dr. Carlos F. MacDonald.

### Book Notices.

*[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]*

*Nerven und Seele.* Von Dr. PAUL KRONTHAL. Mit 139 Figuren im Text. Jena: Gustav Fischer, 1908. Pp. 431.

Goethe has said that "all professional men labor under the disadvantage of not being able to neglect what is useless," and there certainly is no profession to which this applies with more force than the medical profession. At the same time we cannot resist the conviction that in the wisdom of the ancients all is not useless, for it may be recalled that Gomprecht, one of the ablest of modern historians, has said that, if the wisdom of the Greeks had left us nothing more than an outline of the atomic theory, it had made its lasting contribution to the development of human culture. The philosophy engendered by the Greeks has continued to the present time, and it is with much pleasure that, as medical disciples, we note that the physician has always remained a philosopher.

In the volume before us we find one of the most recent attempts to solve the physiological relations which exist between the nervous system and the soul, this time from the pen of a well known neurologist. It would be natural that the mode of approach should be more or less anatomical, and fully one half of the volume before us is devoted to a critical analysis of the structure of the neurone, which, we may say in passing, seems entirely too detailed in its anatomical features for any philosophical correlation. Certainly all the facts which have been patiently dug out in the historical laboratories of the world are here collected. An attempt has been made to show wherein anatomical structure underlies physiological function. The attempt has been too rigidly limited to cytological details, and the much more fascinating features of neurone linking have been neglected.

In attacking the second portion of his problem, namely, the soul, the author first justifies himself by maintaining that the study of the nature of the soul is a natural science idea. The psyche is really the reaction phase only of all external stimuli making an impress on nervous structures. It is the sum of the reflexes due to peripheral stimulation. He therefore discusses in detail more or less what these peripheral reactions are, and endeavors to show how sleep, memory, will, feeling, and reflex are integers in the problem. Kronthal, in a certain sense, departs from most works of a similar character in paying attention to the pathology of the psyche by a full consideration of the insane mental reactions, and through them attempts some explanation of what have been called the soul processes. In this respect it would seem that a fruitful avenue has been traversed, for in the study of the biological sciences it has been demonstrated over and over again that a true knowledge of the physiology of function has only been arrived at through the path of its pathology.

The author's point of view is naturally materialistic. He discusses nerve cells, nerve paths, and nerve impulses, and shows us how far the materialistic point of view may be traveled without difficulty. That he has solved the unsolvable problem of psychophysical parallelism is hardly to be expected. Nevertheless, it is interesting reading, well put together, and remarkably simple so far as the German construction is concerned.

*The Borderland of Epilepsy.* Faints, Vagal Attacks, Vertigo, Migraine, Sleep Symptoms, and their Treatment. By Sir WILLIAM R. GOWERS, M. D., F. R. C. P., F. R. S., Hon. Fellow, Royal College of Physicians, Ireland, etc. Philadelphia: P. Blakiston's Son & Co., 1907. Pp. vi-121. (Price, \$1.25.)

To the narrow student of nervous phenomena this work will come as a shock. All too prone are many physicians to accept a diagnosis of a condition as a finality. Their therapeutics is hypnotized by a word, and an all too prevalent nihilism in the field of treatment renders them powerless before the magic word epilepsy.

But there are epilepsies and epilepsies; those due to irremediable and incorrigible defects of structure—no fewer than fifty pathological defects are known to be the exciting causes of that general symptom picture which, for too many, diagnosed as epilepsy, fails to awaken any desire to discover a cause and seek for a remedy.

Gowers has done well to call attention to a large group of epilepsies in which the irremediable causes are not present, and in which, with proper care, treatment may be instituted which will give enduring benefit. Tonics of this kind are like draughts of cold water; they stimulate and invigorate, and we feel that many are in need of the very excitation that this excellent work will produce.

*Confessions of a Mad Man.* By the Writer of *The Young People*. New York: The Macmillan Company, 1908. Pp. ix-128. (Price, \$1.25.)

This is a book worthy to be placed in the hands of every student of medicine on the day he is graduated. Its conception is lofty, and the literary style of the author has a compelling charm, so that the reader is held captive to the volume until it is read

from beginning to end. All through the ten essays which make up the book there runs a vein of exquisite sensibility which reveals the writer as one who is a lover of his calling, and who, moreover, has the right idea of a calling as distinguished from an avocation. In fact, the first essay in the book is a dissertation on the meaning of the word vocation, the conclusion being reached that, "if a doctor's life may not be a divine vocation, then no life is a vocation and nothing is divine." There is food for thought in every chapter, and the sentiments to which the author gives expression will be relished as much by the old and experienced doctor in practice as by the young man who has just been graduated and has started to make a name for himself. There is much good counsel in the book and plenty of helpful suggestion, all combined with much practical philosophy, bound up in instances with noble examples from the lives of men whose names are writ large in the history of medicine. The chapter on Ambroise Paré will be at the same time a revelation and a well-spring of inspiration for many an ambitious young surgeon, and that not less by the fine moral tone of the writing than by its easy charm of diction and its uplift. It is not a book that lends itself well to quotation; it must be read as a whole and in the spirit of the author, whose *Confession* is not a confession of sins, but a confession of devotion and loyalty to his own profession. Although published anonymously, "by The Writer of *The Young People*," it is easy to guess at the identity of the author, who cannot be other than Dr. Stephen Paget, son of the late Sir James Paget, who is known to be the author of *Our Young People*.

*Nursing the Insane.* By CLARA BARRUS, M. D., Woman Assistant Physician in the Middletown State Homeopathic Hospital, Middletown, N. Y. New York: The Macmillan Company, 1908. Pp. x-409.

In taking from the preface of this work some of the ideas expressed by the author we feel that we can best represent the spirit that animates it. This spirit is one with which we are in cordial sympathy, and we are desirous that it should be more widespread among workers in this most perplexing field.

Within the memory of the passing generation our institutions have been evolved from mere places of detention and custody into modern hospitals, which aim to provide comfortable, pleasant, and hygienic surroundings for the patients, scientific treatment directed to the cure of the curable, and judicious and humane care for all. But even with this highly desirable evolution there are still too many dark places, not peculiar to hospitals for mental disorders alone, but which, when found in such, are all the more deplorable, since so many of the patients are unable by the very disorders from which they suffer to obtain redress.

The inmates of a hospital for mental disorders are for the most part peculiar and trying to treat—peculiar and trying, however, only so long as the old fashioned ideas regarding mental disorders are held to. "To deal with them wisely and kindly requires exceptional qualities of mind and character," writes Dr. Barrus, and we might raise the query, How are such exceptional qualities to be obtained for the miserable pitance which State legislatures dole out to the physicians, nurses, and attendants?

To train nurses and attendants in this special branch of work is the object of this book, and we know of no similar one that approaches the subject in the broad, comprehensive spirit which is so desirable. It is well written, specific, and adequate, and we can commend it most cordially. It is not alone of value to nurses; physicians should read it, as it reflects the proper attitude of mind that is necessary in order to deal adequately with the problems. Such an attitude of mind the physicians of this country themselves are in need of acquiring, and in the volume before us are set forth principles which have been the fruit of a ripe and sympathetic experience.

*Movable Kidneys and Other Displacements and Malformations.* By DAVID NEWMAN, M. D., F. F. P. S. G., Surgeon to the Glasgow Royal Infirmary, etc. New York, Bombay and Calcutta: Longmans, Green, & Co., 1907. Pp. 233.

It is an evidence of the great accumulation of knowledge on special subjects in medical science that there should be material for a fair sized volume on a subject the scope of which, to ordinary observation, is not broad. The author's classification into movable and floating kidney, according as the organ is not or is in the peritoneal cavity, is not very exact, for a floating kidney is certainly a movable one.

Extraperitoneal and intraperitoneal might be more accurate. The latter is rarely seen, and the former frequently causes no symptoms. The author is in favor of nephrorrhaphy whenever the symptoms from the displacement are at all severe. He is rather more radical in this respect than Treves, whose experience is certainly as great, and who believes that an operation is seldom required.

A large number of illustrative cases are reported in detail, and various anomalous conditions of the kidney are represented by very good illustrations. We fail to find anything new, however, in the author's consideration of his subject.

*A Textbook of Minor Surgery.* By EDWARD MILTON FOOTE, A. M., M. D., Instructor in Surgery, College of Physicians and Surgeons (Columbia University), etc. Illustrated by 407 Engravings from Original Drawings and Photographs. New York and London: D. Appleton & Co., 1908. Pp. xxvi-752.

When we first saw this substantial volume, our first thought was one of wonder that so big a book had been written on the subject, for we called to mind the little minor surgeries of the past. But examination of the work shows that the author classes as "minor" the greater part of surgical practice—all of it, we may say, that is not of heroic magnitude. He gives what we must admit is a good reason for doing so, namely, that the authors of the more pretentious recent textbooks of surgery have to a great extent rather slighted those portions of their subject which fall short of the supreme degree of impressiveness. Just this kind of book, therefore, has been needed, and Dr. Foote has given us a good one. His teachings are such as a rather careful examination of the contents does not allow us to find fault with, further than to remark that the regional division has necessarily led to some repetition. The dedication is particularly good: "This book is dedicated to the man at the point of the knife, for his grit and patience, and especially for his willingness to be photographed that others may profit by his misfortune."

The mechanical quality of the volume—in print, paper, pictures, and binding—is most creditable to the publishers.

*Healthy Boyhood.* By ARTHUR TREWBY, M. A. With an Introduction by Sir DYCE DUCKWORTH, M. D., LL. D., Consulting Physician to St. Bartholomew's Hospital, etc., and a Foreword by Field Marshal EARL ROBERTS, K. G., K. P., V. C., O. M., P. C., G. C. B., G. C. S. I., G. C. I. E., D. C. L., LL. D. New York: Longmans, Green, & Co., 1907. Pp. 63.

In the lay press, as well as in our professional journals, we find the question discussed very often: What should a boy know who is entering upon manhood, and who should instruct him; or should this theme be left untouched? Our author thinks that a boy at such a period should be made acquainted with the mysteries of life in a scientific, fatherly way; the introduction into the knowledge of manhood should not be left to chance, but the knowledge should be well expounded to adolescents.

The book may be given to the boy to read, and will thus take the place of verbal instructions by parent or teacher. It can be well recommended to any household, as its language and expression are so guardedly written that nobody can object to it, and only good can come from reading it.

*Rotunda Midwifery for Nurses and Midwives.* By G. P. WRENCH, M. D., Late Assistant Master, Rotunda Hospital. With an Introduction by the Master of the Rotunda Hospital. London: Henry Frowde (Oxford University Press) and Hodder & Stoughton, 1908. Pp. xiv-324.

There are those who think that too many books have been written for the purpose of teaching nurses how to practise medicine more or less, and we admit that our own tendency is toward that opinion. However, the thought would hardly arise if such books were always written so judiciously as this one of Dr. Wrench's. The Dublin Rotunda has always stood high as a source of instruction in obstetrics, and its medical officers may be relied upon to present the subject in a conservative manner.

Dr. Wrench teaches in a most practical way in this book, and he does it in simple and easily intelligible language, though the statement that "white leg" causes morbidity" (page 252) is perhaps more sententious than lucid, and the following statement (page 139) does not seem quite consistent: "Our hospital patients get up on the evening of the seventh and go out on the eighth day. A woman may sit up on the fifth day. She may go out after she has been up for five or six days."

Dr. Wrench says of "quiet rupture of the uterus" (a phrase with which we are not familiar): "This is a form of rupture which occurs without previous signs of threatening rupture. It is not uncommon in Ireland." In such matters as this, as in many others, this little book may be of service to young physicians as well as to nurses and midwives. It is deserving of high commendation.

*Clinical Lectures and Addresses on Surgery.* By C. B. LOCKWOOD, Surgeon to St. Bartholomew's Hospital. London: Henry Frowde (Oxford University Press) and Hodder & Stoughton, 1907. Pp. viii-307.

The volume before us is a second edition, though that is not stated on the title page. The fact of its appearing in the same year with the first edition shows the acceptability of the book. The chapter

headings are as follows: An Introduction to the Study of Clinical Surgery; Clinical Reasoning; The Course of Intraabdominal Inflammation; On the Recognition and Management of Intestinal Obstruction; The Essentials of a Diagnosis; Secondary Infection of the Lymphatic Glands in Malignant Disease of the Tongue; Carcinoma of the Breast and its Spread into the Lymphatics; Varicose Veins; Swellings Above, Below, and Within the Neck of the Scrotum, particularly Inguinal Varicocele and Hydrocele; Exploratory Laparotomy, especially in Cases of Malignant Disease; Faecal Leaks and Fistulae; The Immediate Microscopical Diagnosis of Tumors during the Course of Operations; Clinical Pathology in its Relation to Diagnosis and Treatment; and Salivary Calculi.

So slight a connection is there among most of these subjects that the lectures may fairly be called *disiecta membra*, but they are exceedingly practical and the teaching given in them is wise. The author gives many useful hints that one might look for in vain in a formal textbook. Mr. Lockwood's style is colloquial to an unusual degree, but there is never any doubt as to his meaning. We commend the book without reserve.

*The Influence of Alcohol and Other Drugs on Disease.* The Croonian Lectures Delivered at the Royal College of Physicians in 1906. By W. H. R. RIVERS, M. D., F. R. C. P., Fellow of St. John's College, Cambridge. London: Edward Arnold, 1908. Pp. viii-136.

The lectures printed in this book are those delivered at the Royal College of Physicians, entitled the Croonian Lectures for 1906, differing in their printed form somewhat in details of arrangement and in the addition of new matter from their first presentation, which for the most part took place in the *Journal of Physiology*.

The author first takes up the methods followed in his experiments, dealing with the double problem of individual muscle fatigue and the more psychical factor of general fatigue. He then takes up in detail the drugs studied, caffeine, alcohol, cocaine, strychnine, and tobacco being chosen.

The problems dealt with by Rivers have all received considerable attention from the efforts of physiologists, pharmacologists, and psychiatrists, and in the main his results are confirmatory of those arrived at by the more advanced workers in these fields. To the worker in psychiatry the results are of special interest in that the author confirms in large part the observations of Kraepelin, the psychiatrist, whose researches have given in the past decade the greatest impetus to the forward study of mental disorders.

### Miscellany.

**German Comment on Dr. Rose's Ideas of Medical Language.**—Dr. Herman Triepel, professor of anatomy at the University of Breslau, submitted to the German Anatomical Society at the twenty-second annual convention in Berlin a memorial on anatomical nomenclature. (*Denkschrift über die anatomische Nomenclatur der anatomischen Gesellschaft auf ihrer 22. Versammlung* in Berlin, vorgelegt am 22 April, 1908), endorsing the views and suggestions put forward by Dr. Achilles Rose since 1894. Thus, he also confirms Rose's statement that the work of the Commission on Nomenclature of the German Anatomical Society, now known by the designation of B. N. A., is not perfect, that it is defective in regard to language, and that a thorough revision of the B. N. A. is indicated. During the last few years quite an appreciable number of books have been published, notably also in America, which have adopted the Basle nomenclature, and Triepel is of the opinion that the unopposed dissemination of the imperfections in medical onomatology should be checked. In agreement with Rose, Triepel considers it an important requisite to secure the assistance of Greek colleagues for the linguistic revision of the B. N. A. He points out that the value and position of modern Greek has up to the present time been frequently misunderstood. The Greek written language has preserved to the present day, and with great tenacity, the material features of ancient Greek. In spite of its conservative character, however, it is not dead; it lives in the national consciousness, not only as a written, but also a spoken language. This is the idea to which Rose has given expression in numerous writings, calling attention to the fact that the thesaurus of modern Greek is particularly adapted to supply the technical terms of medical science. Rose is confirmed in saying that only an educated Greek could command the linguistic feeling which is a prerequisite in the formation of new words from the elements of the existing treasure. Of particular importance is the following passage: "If we are in doubt as to the validity of an anatomical name, taken from the Greek language, we shall probably obtain satisfactory information by consulting a Greek textbook of anatomy. For our purposes the most commendable of all Greek textbooks is the one by Papaioannou, the most extensive one in existence. (Sclavuno's textbook is not yet completed.) In order to be able to employ in his work a nomenclature free from objections, Papaioannou studied, as stated in the preface, the writings of the ancient Greek philosophers and physicians. Some of the names he encountered had to be first remodeled, in so far as they did not conform to the strict requirements of the laws of Greek word construction. In many designations which had been misunderstood or mistranslated by European nations, and had been taken over without criticism by modern Greek authors, he had to establish their true meaning in order to find a proper place for them. Other words again have undergone an entirely new formation at his hands, keeping strictly to the applicable linguistic rules. Papaioannou's nomenclature 'is to-day generally employed in Greece in scientific works, lectures, etc.' as his son, Professor Theodore Papaioannou, states. Triepel believes that it is reserved to just that book of Papaioannou to render the most important services in the construction of an improved nomenclature. It is also interesting that on April 14, 1907, the Medical Society of Athens appointed a committee for the purpose of undertaking a revision of the entire medical nomenclature.

## Official News.

Public Health and Marine Hospital Service  
Health Reports:

The following cases of smallpox, yellow fever, cholera, and plague have been reported to the surgeon general, United States Public Health and Marine Hospital Service, during the week ending May 15, 1908:

Places.	Date.	Cases.	Deaths.
Alabama—Mobile, city and county.	April 13-18.	38	17

Peru—Lima.	March 28-April 4.	3	1

## Army Intelligence:

Official list of changes in the stations and duties of officers of the Medical Corps of the United States Army for the week ending May 16, 1908:

ASHFORD, B. K., Captain. Relieved from duty at Washington Barracks, D. C., about July 1st, and ordered to San Juan, P. R., for duty.

BAKER, F. C., Captain. Ordered to Fort Moultrie, S. C., for temporary duty during army and militia defence exercises, June 18th to 28th.

DESHON, G. D., Major. Relieved from duty and station at Fort Des Moines, Ia., and assigned to station and duty at the Army and Navy General Hospital, Hot Springs, Ark.

KOEPFER, C. E., Captain. Granted leave of absence with permission to visit the United States, to sail from Havana, May 22d, and to sail from Newport News, returning, June 15th.

RAFFERTY, O., Major. When relieved from duty at San Juan, P. R., ordered to Fort Wayne, Mich., for duty.

RAYMOND, H. I., Major. Ordered to Washington Barracks, D. C., for treatment at the General Hospital.

VEDDER, E. B., Captain. Granted leave of absence for four months.

## Navy Intelligence:

Official list of changes in the stations and duties of officers in the Medical Corps of the United States Navy for the week ending May 16, 1908:

DENNIS, J. B., Surgeon. Detached from the *South Dakota* and ordered to the *Virginia*.

LOWNDES, C. H. T., Surgeon. Detached from the *Virginia* and ordered to the *South Dakota*.

## Births, Marriages, and Deaths.

## Born.

LYSTER.—In Ancon, Canal Zone, Panama, on Sunday, April 26th, to Dr. Theodore C. Lyster, United States Army, and Mrs. Lyster, a son.

PORTER.—In Key West, Florida, on Thursday, May 7th, to Dr. Joseph Porter, Jr., United States Marine Hospital Service, and Mrs. Porter, a son.

## Married.

GRAHAM—HACKER.—In St. Louis, Missouri, on Tuesday, May 5th, Dr. Thomas E. Graham and Miss Julia E. Hacker.

LITTLE—TADD.—In Philadelphia, on Monday, May 11th, Dr. John Forsyth Little and Miss Edith Jane Tadd.

## Died.

CAMERON.—In Westmoreland, Maryland, on Sunday, May 3d, Dr. Martin F. J. Cameron, aged forty years.

HEINTZ.—In Marion, Arkansas, on Sunday, May 10th, Dr. Louis Ferdinand Heintz, aged thirty-eight years.

HITT.—In Los Angeles, California, on Sunday, May 10th, Dr. S. Merritt Hitt, aged forty years.

HOPKINS.—In Philadelphia, on Tuesday, May 12th, Dr. Ellwood E. Hopkins.

McCANDLISH.—In Emporia, Kansas, on Tuesday, May 5th, Dr. Robert McCandlish, aged eighty-two years.

McCARTHY.—In Barrie, Ontario, on Monday, May 11th, Dr. John Leigh Goldie McCarthy, aged sixty-three years.

MURRAY.—In St. Louis, Missouri, on Thursday, May 7th, Dr. S. J. Murray, aged forty-two years.

STANTON.—In Bridgeport, Connecticut, on Friday, May 8th, Dr. Thomas F. Stanton, aged forty-four years.

STEELE.—In Wayne, Pennsylvania, on Sunday, May 17th, Dr. John Dutton Steele, of Philadelphia, aged forty years.

THOMAS.—In Cumberland, Maryland, on Tuesday, May 5th, Dr. William George Thomas.

#### THE MANAGEMENT OF SELF LIMITED DISEASE.\*

By W. E. KONKLE, M. D.,  
Montoursville, Pa.

The partridge rummaging through brushwood or scratching in forest litter in quest of bug or berry; the heron at the stream, sentinel like, patiently, persistently peering into the shallows for a sign and glimpse of a craved prize; the owl, with impelling hunger, ranging among the mystic shadows of the night; these are the medical specialist in laboratory, or in clinic, or in private practice investigating, observing, exploring. The hawk soaring above house top and tree top and hill top, sailing in unimpeded flight the upper airs, commanding the landscape below from horizon to horizon, that is the medical philosopher, analyzing, classifying, correlating, reconciling the gross findings of the delvers. If placed somewhat at disadvantage as to discernment of facts in their minutia and detail, yet is the general practitioner peculiarly adapted by position and pursuits to the intervaluation and interadjustment and interharmonization of general ideas and general truths. And self evident is it that to orientate is as vitally requisite as to advance.

In a domain only partially explored are the results of exploration, by reason of their patchy, incomplete, disconnected character, liable to appear contradictory or antagonistic. In the field of therapeutics this is found to be notoriously the case. Here, indeed, are the poles of thought and advocacy widely separated, with sons of Arah stoutly holding each antipodal standpoint. On the one side we have von Leyden graciously announcing "*Die Zeiten des Nihilismus in der Klinik und des Pessimismus in der Praxis sind überunden, sie liegen hinter uns.*" ("The times of nihilism in the clinic and of pessimism in practice are surmounted, they lie behind us.") On the other side we find a scholarly and experienced leader courageously attacking even the time cemented stronghold of quinine, and otherwise out-Sangradoing Sangrado in the paucity of his remedial measures, still further narrowing and simplifying the famous formula, "*La saignée et l'eau chaude*" of the Valladolid doctor by replacing its "*la saignée*" with "*l'eau froide*"—water, the alpha and the omega, "water, water everywhere." On one shore of the Atlantic a distinguished teacher firmly maintains that "he is the best doctor who knows the worth of medicines." On the opposite shore a silver

tongue declares that "he is the best doctor who knows the *worthlessness* of medicines." Extremes, however, are in a sense not irreconcilable. Ordinarily antithetic doctrines are neither all right nor all wrong—they mutually look toward a common intermediate truth. Ask "A," who is viewing a given point from the east, what is the direction of approach toward that point, and he will reply westward. Ask "B," who is viewing the same point from the west, what is the direction of approach toward that point, and he will reply, eastward. The function of disinterested criticism is to find between conceptions thus at variance the *juste milieu*. So in the province of therapeutics it will be manifest that between scornful nihilism and arrogant absolutism there should move a discriminating common sense; between sullen pessimism and ecstatic optimism there should operate a progressiveness at once alert and active; between stolid unbelief and frenzied credulity there should reign a reasonable and reasoning scepticism.

Restricting discussion to the confines of our proposed subject, the management of self limited disease, we would apply therein the aforestated theses as criteria. The phraseology, self limited disease, is inaccurate, but so sanctioned by use that in propriety it may not be arbitrarily rejected. It is misleading, however, and needs to be defined. Venturing a definition, we submit that so called "self limited" disease is disease which, with more or less certainty, with more or less safety, with more or less promptness, the natural forces eliminate.

The term "management" is advisably employed. It is meant to indicate direction rather than coercion; influence rather than usurpation; promotion of recovery rather than cure. The term is not exclusive of the idea of specific treatment of disease—indeed, it is entirely compatible with such idea. A specific is, simply, an agent which directly and causally accelerates and safeguards Nature's movement toward health along her own course. The only pity is that we have at our command so few of these agents.

Nether does the method implied in the word "management" debart drugs as remedies. The requirement for modification of some certain physical process does not necessarily carry with it an indication of the exact character and form of the instrument to be selected. Other things being equal, considerations of effectiveness and availability vary properly are determinative at this point. If no special contraindication exists, what reason or wisdom can there be in ignoring the claims of a drug simply because it is a drug? Why is it not logical

\*Read before the University County Medical Society, at Westport, Pennsylvania, April 20, 1908.

and scientific to attain salutary results by extraordinary means where ordinary measures fail or are lacking?

Arriving at the immediate and intimate discussion of our subject, I would submit first of all and most prominently that the primary and fundamental factor in the management of self limited disease is the thorough, the exhaustive, the lucid, the commanding comprehension of the natural course of such disease. We must know clearly and fully the features of the typical case, and we must know the safe and permissible deviations therefrom. We must be familiar with the symmetry of symptoms, and we must be able to recognize the bounds of unessential asymmetry of the same. Just so far as we do not *know* are we bound to keep our hands off. Merest hazard even is as safe a guide as ignorance; certainly a usually benign natural order will be immeasurably more trustworthy than sightless eyes. "God moves in a mysterious way his wonders to perform." Nature to the doctor is divine. If he be not initiated into her mysteries he must not presume to assist at her offices. The doctor who is keenly, humbly conscious of what he does not know will refrain from positive action beyond the limits of his knowledge. He will prefer the risk of negative error. He will choose not to do rather than to do by chance. In assuming this position he will, of course, bring himself within the range of the thrust of La Bruyère where, in his *Characters*, he satirizes our profession thus: "La témérité des charlatans, et leurs tristes succès, qui en sont les suites, font valoir la médecine et les médecins; car ceux-ci laissent mourir, les autres tuent." ("The temerity of quacks, and their sad successes which are the consequences of it, make for the reputation of medicine and of physicians; for the latter simply let people die, while the former kill them.")

But far better is it to render ourselves liable to such shafts of irony as aimed at a conservative negativism than to incur just criticism of the kind embodied in his epigram on "The Physician" by the German fabulist, Nicolay, which I beg leave to quote:

*"Wenn Uebel und Natur in einem Körper streiten,  
So kommt ein blinder Arzt und haut nach beiden  
Seiten;*

*Wenn er das Uebel trifft, so stellt er wieder her;  
Wenn die Natur, so tödtet er."*

This may be translated as follows: "When a disorder and Nature are battling in a human body, there comes a blind doctor and slashes toward either side; if he chances to hit the disorder, he restores to health again; if he chances to hit Nature he kills."

Truly he charges himself with an awful responsibility who dares to supplant Nature—to censor and alter her plans of operation—to halt or modify her processes and procedures. It is a very serious matter to administer a really active dose of a potent drug; to do it intelligently is eminently proper; to do it at random is altogether reprehensible. In alluding to certain desperate conditions, where one sick is at the very last extremity, Celsus coined the dictum, "*Melius est anceps remedium quam nullum*"—"Better a hazardous remedy than none." This

proposition of the Cicero of medicine his commentators have quite generally reprobated. Bouchut apologizes for it only on the ground that it was applied by its famous author solely to cases practically devoid of hope except as hope might remain in the caprice of some heroic intervention.

In the management of self limited disease immediately after the requirement of adequate acquaintance with the natural history of such disease comes the obligation to see that this natural history be normally developed. The single but solemn duty of the doctor here is to have the disease keep its due course, or maintain its symmetry. He can do no *more* than that; he should try to do no more. His province includes no *less* than that; he should aim at no less. As a corollary of his obligation to see that these diseases hold their course stands the further obligation to not interfere when that course is being followed. Symptom tinkering is extremely pernicious, can do naught but harm, where a proper balance or proportion between the symptoms already exists. In illustration take temperature. Not so long ago it was thought good practice to depress exalted temperature, regardless of its relationships; now it is coming to be considered a useful factor, and its deficiency within bounds is deplored.

Thus far our discussion has been general. Let us now briefly touch a few points in particular. And first it may be mentioned that in self limited disease, as, indeed, also in every other condition of disease, the problems of heredity and habit and environment and idiosyncrasy—in fact, all those elements which make an individual an individual and render every case a case by itself, all this should be taken into the reckoning. Sir Dyce Duckworth has recently entered protest against the tendency of medicine to neglect the personal. It would seem that it has been peculiarly Osler's mission to champion the claims of man to be dealt with even in a medical way as a human being unique and unduplicated, rather than as an animate lump of matter of distinctly generic mould.

In every case of self limited disease rest and sleep should be given careful attention. To this end pain of a degree that is distressing and exhausting should be controlled. Of course the heart should be assiduously, untiringly watched. A consideration of vital importance is the efficient performance of their functions by the emunctories—this cannot be overemphasized. Nutrition should be looked after; but here again natural indications should be closely studied—we should be careful not to say *eat*, when Nature says *fast*. Water will be the indispensable food.

Many of us are quite familiar with river rafting. The management of self limited disease, it seems to the writer, is like unto that. Is the raft duly in its channel? On the bosom of the current undisturbed let it float—the river will strongly, securely bear it forward—the motionless oars will be the certain sign that all is well. Has the raft drifted out of its channel? Let there be no hesitation or delay; let a "long pull and a strong pull and a pull all together" bring it back where rafts are wont to go. Yonder is the pilot—mostly standing with folded arms, his eyes bent on stream and shore ahead.

Now he directs a slight adjustment this way and now that way, and again he urges a mighty, a resolute effort against a power drawing his raft toward rock or shoal. He does not have things done only later to have them undone. Never does he lose his head; if he should he would lose his raft. He knows where he is and whither he is going; if he did not he would not be a pilot. Probably he will arrive down river without loss. Should his raft ground or "stove" he will not be at fault.

Yes, the medical man is the counterpart of the riverman. Like him he has a charge to guide down the angry current of a flood from which there is no escape except in the quiet waters below. Similar knowledge should be his, and similar principles should govern him. He can do no more than the riverman, albeit his trust is incomparably momentous. To know the courses, and to wisely, skillfully strive to hold them is the measure of possible competency. Let him, then, simply be another captain of a raft. In failure he, too, will be faultless. But if at last his raft glides out upon a serene expanse beneath sunny skies, even though the oars have been most of the time idle, for what he did *not* do as much as for what he *did* do he will be a victor—he will be a pilot—he will be a doctor.

#### CONDITIONS AFFECTING THE PROPORTIONS OF FAT AND PROTEINS IN COW'S MILK.

BY L. L. VAN SLYKE, Ph. D.,  
Geneva, N. Y.,

Chemist of the New York Agricultural Experiment Station.

In the utilization of cow's milk in infant feeding a knowledge of the proportion of fat and proteins is of fundamental importance. The assumption, so common in works on infant feeding and in practice, that fat and proteins in cows' milk are present in fairly uniform percentages, is not supported by the actual facts.

The accumulation of extensive data in the records of this station bearing on the subject of this paper furnish abundant material for a somewhat detailed discussion. Briefly stated, these records include the following data: (1) Analyses of the mixed milk of numerous herds of cows, as obtained at cheese factories in this State. We have over three hundred such analyses, representing results of work done during several different factory seasons (April to November). (2) Analyses of the milk of each of fifty different herds of cows, whose milk was taken to one cheese factory, analysis being made every other week from April through October. This work furnished about 650 analyses of herd milk, such as is common in the dairy regions of this State. (3) Analyses of milk of individual cows, representing a systematic investigation covering entire periods of lactation. Seven different breeds are represented, each with three to six individuals, the results covering for each individual one to eight periods of lactation. This work has furnished several thousand analyses of milks. The extent of our data is such that in the limits of this article they can be used only in the digested form of summaries or in illustration of specific details.

It is the purpose of this article to present data

showing, (1) the range of variation in the amounts of fat and proteins in milk; (2) the conditions which influence variation of these constituents; (3) the variations in the relation of fat to proteins; and (4) some of the practical applications of the facts presented.

#### *General Range of Variation in the Percentages of Fat and Proteins in Milk.*

The extreme variation possible in cow's milk is a matter of general rather than practical interest. As such, we first present the results furnished by our records. As would be expected and as is well known, the variations in the percentages of constituents are much greater in the case of single milkings of individual cows than in the case of averages for entire periods of lactation, or than in the case of the mixed milk of a herd of cows, or than in the case where the milk of several different herds is mixed. Of course, practically all the milk handled in commerce is either the milk of individual herds or the mixed milk of numerous herds.

(1) *Fat*.—Taking all the results in our records for the single complete milkings of individual cows, the lowest percentage of fat found is 2.25 and the highest 9; the minimum amount being found in the milk of a Holstein-Friesian cow, the maximum in that of a Jersey cow that was far along in lactation. During a period of lactation (usually ten to twelve months) the fat in the milk of an individual cow may vary, in the case of single milkings, more than three per cent., from lowest to highest. The extreme variation of fat between two successive milkings (night and morning) may be as much as two per cent. in the case of the same animal.

The percentage of fat in the milk of individual cows for an entire period of lactation, according to our records, is a minimum of 2.79 (Holstein-Friesian) and a maximum of 6.30 (Jersey).

In the case of individual herds of cows, such as are common in the dairy regions of this State, the minimum percentage of fat on any one day was found to be 2.90; the maximum, 5.50, which occurred late in the season (October). The lowest season average for any one herd was 3.31 per cent.; the highest, 4.31 per cent.

In the case of milk consisting of a mixture of the milk of different herds, the lowest percentage of fat found was 3.04 and the highest 4.60.

*Proteins*.—For the purpose of this article we can consider the proteins of milk as consisting of casein and albumin.

In the single milkings of individual cows we have found as low as 2.19 per cent. of total proteins and as high as 8.56 per cent., the casein varying from 1.59 to 4.49 per cent., and albumin from 0.31 to 5.32 per cent. The highest percentages were found in the case of cows far along in lactation and giving only small amounts of milk. Such milk is, of course, not normal from a commercial standpoint and possesses interest mainly in showing what the secretion may become under certain known conditions.

The percentage of proteins in the milk of individual cows for an entire period of lactation varies from 2.87 to 4.44, of casein, from 1.00 to 3.58 and of albumin, from 0.47 to 4.00.

In the case of individual herds of cows, the per-

centage of proteins ranged from 2.31 to 3.71; of casein, from 1.79 to 3.02; and of albumin, from 0.41 to 0.97.

In the case of milk consisting of a mixture of the milk of different herds of cows, the percentage of proteins varied from 2.53 to 3.76; of casein, from 1.93 to 3.00; and of albumin, from 0.47 to 0.88.

#### *Conditions Affecting Variations of Fat and Proteins in Milk.*

The conditions of the marked variations observed in the amounts of constituents in cow's milk have received considerable study, and many of our data are available, with special reference to this phase of the subject, which will be discussed under the following headings: (1) Individuality, (2) breed, (3) stage of lactation, (4) food, (5) season, (6) manner and time of feeding.

(1) *Individuality.*—In examining the results of analysis of single milkings in the case of two or more individual cows, one is first impressed with the marked differences usually existing. If one carries on the study of individuals for prolonged periods of time, it will be noticed that, while the composition of the milk of each may vary quite widely in single milkings at different times, each possesses certain characteristics that serve to distinguish it in a manner more or less marked. To change the composition of the milk of a cow to such an extent that it loses its individual characteristics requires extreme and abnormal conditions; and even when such changes are effected, they are usually only temporary. Probably no question in animal nutrition has attracted so much attention along practical lines as that of changing the percentage of fat in milk by means of feeding, or, to state it in another form, the problem of overcoming through food the influence of individuality. The problem has not yet been solved, at least not in an economical form, and it is generally regarded by students of animal nutrition as a dairyman's will-o'-the-wisp. A few analyses are given in Table II, illustrating individuality in a general way.

(2) *Breed.*—The influence of what is known as breed upon the composition of cow's milk has been recognized and extensively studied. The following figures, representing in the case of each of seven different breeds averages of three to six individuals of each breed for an aggregate of four to twenty periods of lactation, will illustrate the point under consideration.

TABLE I. FAT AND PROTEINS IN MILK OF DIFFERENT BREEDS OF COWS.

Name of breed.	Fat, per cent.	Proteins, per cent.	Casein, per cent.	Albumin, per cent.
1. Holstein-Friesian.....	3.29	3.24	2.29	0.64
2. Ayrshire.....	3.29	3.07	2.49	0.61
3. American Holsteins.....	4.01	3.45	2.63	0.69
4. Shorthorn.....	4.02	3.43	2.79	0.64
5. Devon.....	4.89	3.93	3.10	0.83
6. Guernsey.....	3.98	3.39	2.91	0.65
7. Jersey.....	5.78	3.68	3.03	0.65

The characteristics of a breed are, of course, more or less modified in the case of individuals, so that we may have quite wide variations in the percentages of fat and proteins in the milk of different individuals of the same breed; but it is extremely rare that the individual characteristics overcome those of breed to such an extent that we should, for

example, not be able to distinguish normal Guernsey or Jersey milk from Holstein or Ayrshire milk, even in the case of single milkings. While extreme variations in the case of individuals of the same breed can be thoroughly studied only with single milkings, the average differences for entire periods of lactation are very marked, as is illustrated in the case of two breeds by the following figures.

TABLE II. DIFFERENCES IN PERCENTAGE OF FAT AND PROTEINS IN MILK OF INDIVIDUALS.

	Fat.	Proteins.	Casein.	Albumin.
Individual Jerseys:				
1.....	5.49	3.57	2.91	0.66
2.....	5.61	3.44	2.83	0.61
3.....	5.77	3.69	2.91	0.78
4.....	6.04	3.87	3.19	0.68
5.....	6.15	3.96	3.42	0.54
Individual Holstein-Friesians:				
1.....	3.95	2.97	2.29	0.68
2.....	3.11	2.60	2.11	0.49
3.....	3.16	2.99	2.41	0.55
4.....	3.19	2.62	2.27	0.65
5.....	3.53	3.34	2.70	0.64

(3) *Stage of Lactation.*—From the time a cow "comes fresh in milk" up to the time when she becomes "dry," the composition of the milk undergoes a gradual process of change, quite independent of other conditions. The period of lactation varies in length with different individual cows, but, for practical purposes, lasts about ten to twelve months. The changes in the percentages of fat and of proteins observed during the progress of the lactation period are quite marked and fairly regular, without reference to individual or breed. The colostrum, the secretion produced by a cow soon after calving, is very different in composition from normal milk, and is not considered at all in our discussion. The figures presented in the following table represent the monthly averages of nearly 100 different lactation periods.

TABLE III. INFLUENCE OF LACTATION ON PERCENTAGES OF FAT AND PROTEINS IN MILK.

Month of lactation.	Fat.	Proteins.	Casein.	Albumin.
1.....	4.39	3.16	2.54	0.62
2.....	4.11	2.99	2.42	0.57
3.....	4.21	3.04	2.46	0.58
4.....	4.28	3.13	2.52	0.61
5.....	4.38	3.25	2.61	0.64
6.....	4.53	3.33	2.68	0.65
7.....	4.57	3.40	2.74	0.66
8.....	4.59	3.47	2.80	0.67
9.....	4.67	3.57	2.90	0.67
10.....	4.90	3.79	3.01	0.78
11.....	5.07	4.04	3.13	0.91

In studying this table, we notice that the percentages of fat and proteins drop in the second month of lactation, as compared with the first, and then begin to increase, continuing to increase from month to month during the entire period of lactation. Such behavior appears to be the general rule. Occasionally, an individual may, for a single period of lactation, depart quite widely from the general tendency. Individuals usually, but not always, show much of the uniformity observed in the results shown in Table III. The occasional variations from the general tendency are due to special, temporary causes in each case, usually connected with such conditions as weather, health, care, etc.

In the tenth and eleventh months of lactation, the increase of fat and proteins is more marked than during the preceding months. In the case of cows whose lactation period is prolonged for one and a half or two years, with a good flow of milk, the percentages of fat and of proteins may not continue to increase, but may even decrease.

In this connection, it will be a matter of interest

to consider the influence of advancing lactation upon the percentages of fat and of proteins, as observed by us in the case of milk used at cheese factories in this State; because this milk represents the condition present in the large milk producing sections of the State. In general, dairymen have their cows "come fresh in milk" in March and April, so that the milk taken to a cheese factory (or sent to the city markets) represents during the season (April to November) stages of the lactation period extending from about the second to the eighth months. Cows kept under ordinary farm conditions are subject to greater variation of external influences than in the case of the cows used in our station investigation. The following figures give the results of our work with cheese factory milk.

TABLE IV. INFLUENCE OF LACTATION ON PERCENTAGES OF FAT AND PROTEINS IN CASE OF CHEESE FACTORY MILK.

Month.	Fat, percent.	Proteins, percent.	Casein, percent.	Albumin, percent.
April	3.43	2.81	2.59	0.22
May	3.38	3.02	2.34	0.68
June	3.64	3.43	2.42	0.99
July	3.62	3.07	2.43	0.60
August	3.81	3.02	2.39	0.63
September	3.92	3.20	2.55	0.65
October	4.23	3.55	2.81	0.74

These results show, in general, an increase in the percentages of fat and of proteins similar to that observed in Table III. The irregularities shown in July and August, especially by a decrease in proteins, will be considered later.

(4) *Food*.—It has been stated already that, under normal conditions, the percentage composition of milk is little influenced by variations in food. In the course of our studies of cheese factory milk, it was noticed that, under certain conditions, marked changes in composition take place. Each year of our studies it was observed that about the middle of May there was a marked increase of fat and proteins. Thus the difference in composition of milk between the first half and the second half of May in one season is shown by the following figures:

	Fat, percent.	Proteins, percent.	Casein, percent.	Albumin, percent.
First half of May	3.49	2.88	2.45	0.43
Second half of May	3.70	3.17	2.48	0.69

A careful study of all the available facts justifies the explanation that these changes were largely due to a marked change in the character of the food and environment of the cows, since they were turned into pasture about the middle of May. Under the known existing conditions, there was thus a change from dry food of an indifferent character, mainly straw or poor hay without grain, to a highly succulent food of a most palatable and nutritious character. It is probable that the change of environment of the cows from confinement in barn and yard to the freedom of the pasture exercised a beneficial physiological influence.

In Table IV it is noticed that there is a marked decrease of proteins in July and August. Similar changes were always observed in the case of cows kept at pasture without supplementary sources of food whenever there was a period of drouth sufficiently severe to cause a drying up of pastures. Under such circumstances, the main food supply was seriously affected. The changes in composition of milk were accompanied by severe shrinkage in

yield of milk. Accompanying this impaired condition of food supply, the animals were subjected to the unfavorable effects coming from excessive heat, combined with annoyance of flies. Such changes in composition and yield of milk do not occur in times of drouth in the case of cows which are protected from the effects of extreme weather and whose food supply is kept normal.

(5) *Season*.—The influence of season upon variations in the composition of milk, apart from the effect of advancing lactation, is, to a considerable extent, associated with that of food supply, as indicated by the discussion preceding. When conditions are normal or when cows are properly protected from the effects of abnormal weather conditions, variations in the composition of milk appear to be quite independent of seasonal influences.

(6) *Time and Manner of Milking*.—The composition of the milk given by an individual cow may be much influenced by the conditions under which milking is done. We shall consider three conditions: (a) Time between milkings; (b) fractional milking of the whole udder; and (c) milking different quarters of udder separately.

(a) *Time Between Milkings*.—In general, when the time between successive milkings is the same, the composition of the milk varies little in the absence of any special, disturbing influence. Averaging about 500 analyses, each, of morning's and evening's milk, representing 15 cows, we find the morning's milk to contain 100 parts of fat, as compared with 99.06 parts in the evening's milk, and 100 parts of proteins for 98.34, the time between the milkings being as nearly uniform as possible. However, if we consider single milkings of an individual cow, we may, in special instances, find considerable variation, in illustration of which the following figures are given:

TABLE V. PERCENTAGES OF FAT AND PROTEINS IN MORNING'S AND EVENING'S MILK.

Date.	Fat	Proteins	Casein	Albumin
Dec. 13th, a. m.	5.00	4.16	3.8	0.4
Dec. 13th, p. m.	6.00	4.28	3.8	0.8
Dec. 20th, a. m.	6.00	4.19	3.26	0.93
Dec. 20th, p. m.	6.00	3.93	3.99	0.94
Dec. 27th, a. m.	5.80	4.49	4.51	0.8
Dec. 27th, p. m.	4.48	3.8	3	0.8
Jan. 4th, a. m.	4.20	4.47	3	0.8
Jan. 4th, p. m.	4.20	4.23	3.8	0.4

(b) *Fractional Milkings of Whole Udder*.—The first portions of milk drawn from a cow's udder are very unlike normal milk in composition, showing a marked deficiency of fat. Each successive portion of milk drawn increases in fat content and the last portions drawn usually contain twice as much fat as normal milk. In illustration of these statements, we give analyses of the milk of a Guernsey cow, representing milk drawn successively from the whole udder in four fractions.

TABLE VI. ANALYSES OF FAT AND PROTEINS IN MILK OF WHOLE UDDER.

Fraction	Fat, percent.	Proteins, percent.	Casein, percent.	Albumin, percent.
First	0.1	0.1	0.1	0.1
Second	0.1	0.1	0.1	0.1
Third	0.1	0.1	0.1	0.1
Fourth	0.1	0.1	0.1	0.1
Whole milk of	3.6	3.15	2.7	0.45

While the fat increases rapidly with each successive portion of milk drawn from the udder, the proteins decrease slightly, as would be expected

from the mere presence of increase of fat. The work was repeated by us with several different cows and the several sets of corresponding analyses show similar results.

(c) *Milking Different Quarters of Udder.*—As the result of a large number of analyses of milk drawn separately from each quarter of the udder, it appears that the milk in each quarter possesses individual characteristics of composition, the extent of difference between the quarters varying in the case of different cows. The following figures furnish an illustration:

TABLE VII. PERCENTAGES OF FAT AND PROTEINS IN MILK FROM DIFFERENT QUARTERS OF UDDER.

Quarter of udder.	Fat.	Proteins.	Casein.	Albumin.
Left hind quarter	4.15	2.97	2.33	0.64
Left forward quarter	4.60	2.94	2.32	0.62
Right hind quarter	5.20	2.89	2.31	0.58
Right forward quarter	5.20	2.96	2.38	0.58

The variations in percentage of fat are much greater than in the case of proteins.

Not only does the composition of the milk in one quarter of the udder differ from that in other quarters, but the composition in the same quarter varies according to the order, relative to the other quarters, in which the milk is drawn, as shown by the following example:

TABLE VIII. PERCENTAGE OF FAT AND OF PROTEINS IN MILK OF SAME QUARTER OF UDDER WHEN DRAWN IN DIFFERENT ORDER RELATIVE TO OTHER QUARTERS.

Left forward quarter of udder.	Fat.	Proteins.	Casein.	Albumin.
When milked first	5.10	2.85	2.30	0.55
When milked second	4.85	3.00	2.40	0.60
When milked third	4.60	2.96	2.36	0.60
When milked fourth	3.95	2.91	2.35	0.50

### Variations in the Relation of Fat to Proteins in Cow's Milk.

We have thus far considered the conditions which affect the percentages of fat and of proteins in milk, without paying attention to the relative variations of these constituents. It now remains to study the effect of various conditions upon (1) the relation of fat to total proteins, (2) the relation of fat to casein, and (3) the relation of casein to albumin.

*Conditions Affecting the Relation of Fat to Total Proteins and to Casein in Milk.*—This phase of our subject will be briefly considered under the headings already used in discussing the general subject preceding and the figures already presented in the foregoing tables will be utilized in furnishing desired data.

(a) *Breed.*—The influence of breed in affecting the relation of fat to proteins is shown in the following table, the data of which are derived from Table I:

TABLE IX. INFLUENCE OF BREED UPON RELATION OF FAT TO PROTEINS.

Breed.	Fat, per cent.	Proteins, per cent.	Parts of	Casein, per cent.	Parts of
			fat to proteins, 1 part of fat. Fat : Proteins.		casein for 1 part of fat. Fat : Casein.
1. Friesian	3.26	2.84	1 : 0.87	2.20	1 : 0.67
2. Ayrshire	3.76	3.07	1 : 0.82	2.46	1 : 0.65
3. American					
Holstein	4.8	4.1	1 : 0.87	2.63	1 : 0.66
Jersey	4.8	4.1	1 : 0.86	2.59	1 : 0.65
4. Guernsey	4.89	4.2	1 : 0.86	2.59	1 : 0.65
5. Galloway	5.2	4.6	1 : 0.66	2.91	1 : 0.53
7. Jersey	5.78	3.68	1 : 0.64	3.03	1 : 0.52

It is seen that the different breeds represented separate into two general groups in relation to the ratio of fat to total proteins and to casein in milk. In the case of the first five breeds, the ratio of fat

to proteins or to casein does not vary widely. The milk of the Holstein-Friesian breed contains least fat and most proteins in relation to fat. In the case of the next four breeds in the list the fat varies from 3.76 to 4.89 per cent., but the proteins also vary in very nearly the same ratio as the fat. The Guernsey and Jersey breeds constitute the second group, the fat being high in amount, but the proteins relatively low. These two breeds vary comparatively little in reference to the ratio of fat, either to the proteins or to casein.

(b) *Individuality.*—We will notice briefly the variations that occur in case of different individuals of the same breed. The figures in the following table are derived from Table II and represent the averages for an entire period of lactation in the case of several different individuals of two breeds. More marked differences could be obtained, of course, by taking single milkings or monthly averages.

TABLE X. INFLUENCE OF INDIVIDUALITY UPON THE RELATION OF FAT TO PROTEINS.

Individual Jersey.	Fat, per cent.	Proteins, per cent.	Parts of	Casein, per cent.	Parts of
			fat to proteins, 1 part of fat. Fat : Proteins.		casein for 1 part of fat. Fat : Casein.
1	5.19	3.57	1 : 0.64	2.91	1 : 0.56
2	5.01	3.44	1 : 0.63	2.83	1 : 0.53
3	5.77	3.69	1 : 0.64	2.91	1 : 0.50
4	6.04	3.87	1 : 0.61	3.19	1 : 0.59
5	6.15	3.96	1 : 0.65	3.43	1 : 0.53
Individual Holstein-Friesians:					
1	3.95	2.97	1 : 0.97	2.29	1 : 0.75
2	3.17	2.60	1 : 0.84	2.11	1 : 0.68
3	3.16	2.96	1 : 0.94	2.41	1 : 0.76
4	3.19	2.92	1 : 0.91	2.27	1 : 0.71
5	3.53	3.34	1 : 0.95	2.70	1 : 0.77

Whether we take the ratio of fat to proteins or of fat to casein, there would be very little difficulty in identifying any individual in the list with its proper breed, even though there is some range of variation between the individuals of each breed.

(c) *Stage of Lactation.*—We have previously noticed that during the period of lactation the fat and proteins increase gradually and quite regularly. We will now consider the question as to whether these constituents increase in the same ratio. The data in the following table are derived from the figures given in Table III.

TABLE XI. INFLUENCE OF STAGE OF LACTATION UPON THE RELATION OF FAT TO PROTEINS.

Month of lactation:	Fat, per cent.	Proteins, per cent.	Parts of	Casein, per cent.	Parts of
			fat to proteins, 1 part of fat. Fat : Proteins.		casein for 1 part of fat. Fat : Casein.
1	4.19	3.16	1 : 0.74	2.84	1 : 0.50
2	4.11	2.99	1 : 0.67	2.62	1 : 0.50
3	4.23	3.04	1 : 0.72	2.16	1 : 0.58
4	4.25	3.13	1 : 0.74	2.52	1 : 0.50
5	4.38	3.25	1 : 0.74	2.61	1 : 0.60
6	4.53	3.33	1 : 0.74	2.68	1 : 0.59
7	4.87	3.49	1 : 0.74	2.74	1 : 0.60
8	4.90	3.47	1 : 0.73	2.84	1 : 0.61
9	4.67	3.57	1 : 0.76	2.90	1 : 0.62
10	4.90	3.79	1 : 0.77	3.01	1 : 0.62
11	5.07	4.04	1 : 0.80	3.13	1 : 0.62

An examination of the fourth and of the last columns in the above table shows a remarkable uniformity in the ratio of fat to total proteins and to casein throughout most of the period of lactation. During the first three months a very slight tendency appears for the fat to increase with reference to proteins, or, stated another way, for the proteins to decrease in proportion to fat. After this there is very close uniformity in the ratio of fat to proteins up to the eighth month, after which the total proteins increase gradually in relation to fat to the end

of the lactation period. During the last three months of lactation, the fat increases quite rapidly, but the proteins increase even more rapidly in relation to fat. During this period the casein increases in exact proportion to fat, maintaining a uniform ratio that is very striking. The close uniformity observed in Table XI is not always so marked, of course, in every individual case, but the tendency shown is a very general one.

In this connection, we will use the data embodied in Table IV to illustrate the relations under consideration in the case of the mixed milk of many herds of cows, as obtained at cheese factories.

TABLE XII. INFLUENCE OF SEASON OF LACTATION UPON THE RELATION OF FAT TO PROTEINS IN CHEESE-FACTORY MILK.

Months.	Fat, Proteins, per cent.		Parts of casein, proteins for 1 part of fat.		Parts of casein, proteins for 1 part of fat.	
	cent.	cent.	Fat: Proteins.	cent.	Fat: Casein.	cent.
April	3.13	2.81	1:0.82	2.29	1:0.77	
May	3.58	3.02	1:0.84	2.34	1:0.82	
June	3.64	3.24	1:0.83	2.47	1:0.88	
July	3.62	3.07	1:0.85	2.03	1:0.77	
August	3.84	3.09	1:0.79	2.09	1:0.62	
September	3.90	3.20	1:0.82	2.20	1:0.75	
October	4.23	3.55	1:0.84	2.81	1:0.76	

The amount of total proteins shows a tendency to increase relative to fat for a few months, when a decrease occurs, which is followed by a later increase. The casein maintains a fairly uniform relation to fat during the whole season, except during August, when a decrease was caused by the effect of drouth upon pasturage and attendant unfavorable conditions.

(d) Food and Season.—Attention has previously been called to the effect of turning cows into pasture, as manifested by changes in the composition of milk in the first and second half of the month of May. We will now notice whether the relation of fat and proteins is changed.

	Fat, Proteins, per cent.		Parts of casein, proteins for 1 part of fat.		Parts of casein, proteins for 1 part of fat.	
	cent.	cent.	Fat: Proteins.	cent.	Fat: Casein.	cent.
First half of May	3.46	2.95	1:0.82	2.05	1:0.60	
Second half of May	3.70	3.17	1:0.86	2.45	1:0.66	

It is seen that while total proteins increased with reference to fat, the ratio of casein to fat changed only slightly.

(e) Conditions of Milking.—An inspection of Tables V, VI, VII, and VIII indicates that the total proteins and the casein also remain fairly uniform while the fat may vary greatly in the case of milk drawn from the udder in fractional portions, in the case of milk drawn from different quarters of the udder, etc.

#### Conditions Affecting the Relation of Casein to Albumin in Milk

The general statement has been prominently current in medical literature to the effect that casein and albumin are present in cow's milk in very constant relative proportions, the amount of casein being five times that of albumin. Taking herd milks, we have found the casein varying all the way from 2.6 to 5.6 parts for one part of albumin. In single milkings of individual cows, the variations are considerably wider. The data already presented enable us to study this question under a variety of conditions.

(a) Breed.—The variation of albumin in relation to casein in the case of different breeds of cows is shown in the following table, the data of which are derived from Table I:

TABLE XIII. INFLUENCE OF BREED UPON RELATION OF CASEIN TO ALBUMIN.

Name of breed.	Proteins, per cent.		Casein, per cent.		Albumin, per cent.		Parts of casein to 1 part of albumin.		Percentage of total proteins in form of casein.		Percentage of total proteins in form of albumin.	
	per cent.	per cent.	per cent.	per cent.	per cent.	per cent.						
1. Holstein-Friesian	2.84	2.20	0.64	1:3.4	77.5	22.5						
2. Ayrshire	3.07	2.46	0.61	1:4.0	80.1	19.9						
3. American Holderness	3.32	2.63	0.69	1:3.8	79.2	20.8						
4. Shorthorn	3.04	2.50	0.62	1:4.5	80.3	19.7						
5. Devon	3.03	2.48	0.62	1:4.5	80.3	19.7						
6. Guernsey	3.56	2.91	0.82	1:4.3	81.7	18.3						
7. Jersey	3.68	3.03	0.95	1:4.7	82.3	17.7						

In studying the results embodied in Table XIII, it is noticeable that the casein and albumin vary more or less in their relative proportions in the case of different breeds of cows, and in no case is the proportion of casein to albumin as high as is ordinarily stated (five to one). It is also noticeable that, in general, the albumin forms a larger proportion, and the casein a smaller proportion, of the proteins in milk that contains a low percentage of fat than in case of milk containing a high percentage of fat, when we compare the milk of different breeds of cows. Thus, in the milk of Holstein-Friesian cows, we have the least amount of fat, and the albumin forms a larger part (22.5 per cent.) of the proteins than in case of any other breed under discussion. In the case of Guernsey and Jersey milk, in which the fat content is highest, the proportion of albumin with reference to total proteins or to casein is least (17.7 and 18.3 per cent. of total proteins).

(b) Individuality.—For illustration of the relative proportions of casein and albumin in the case of the milk of different individuals of the same breed, we take the data embodied in the following table from Table II:

TABLE XIV. INFLUENCE OF INDIVIDUALITY UPON RELATION OF CASEIN TO ALBUMIN IN MILK.

Individual Jersey:	Fat, Proteins, per cent.		Parts of casein, proteins for 1 part of fat.		Parts of casein, proteins for 1 part of fat.	
	cent.	cent.	Fat: Proteins.	cent.	Fat: Casein.	cent.
1	3.46	2.95	1:0.82	2.05	1:0.60	
2	3.70	3.17	1:0.86	2.45	1:0.66	
3	3.46	2.95	1:0.82	2.05	1:0.60	
4	3.70	3.17	1:0.86	2.45	1:0.66	
5	3.46	2.95	1:0.82	2.05	1:0.60	
6	3.70	3.17	1:0.86	2.45	1:0.66	
7	3.46	2.95	1:0.82	2.05	1:0.60	
8	3.70	3.17	1:0.86	2.45	1:0.66	
9	3.46	2.95	1:0.82	2.05	1:0.60	
10	3.70	3.17	1:0.86	2.45	1:0.66	

We see marked variation in the relation of casein to albumin in the case of the milk of different individuals of the same breed, the ratio varying in case of the Jersey from 2.7 to 5.3 parts of casein

for one of albumin, and in case of the Holstein-Friesians, from 3.2 to 4.4.

(c) Stage of Lactation.—Making use of the data given in Table III, we are able to prepare the following table:

TABLE XV. INFLUENCE OF LACTATION UPON RELATION OF CASEIN TO ALBUMIN.

Month of lactation	Proteins, per cent.	Casein, per cent.	Albumin, per cent.	Parts of casein for 1 part of albumin	Albumin : Casein	Percentage of total proteins in form of casein	Percentage of total proteins in form of albumin
1	3.16	2.24	0.92	1:4.1	80.4	19.6	
2	3.30	2.42	0.88	1:4.2	80.0	19.1	
3	3.04	2.40	0.64	1:4.2	80.0	19.1	
4	3.13	2.52	0.61	1:4.1	80.5	19.5	
5	3.25	2.51	0.74	1:4.1	80.3	19.7	
6	3.33	2.68	0.65	1:4.1	80.8	19.2	
7	3.40	2.74	0.66	1:4.2	80.6	19.4	
8	3.47	2.80	0.67	1:4.2	80.7	19.3	
9	3.57	2.90	0.67	1:4.3	81.2	18.8	
10	3.79	3.01	0.78	1:3.9	79.4	20.6	
11	3.94	3.13	0.81	1:3.4	77.5	22.5	

The relation of casein and albumin, as shown by the foregoing data, is remarkably uniform during the first eight months of lactation, varying between 4.1 and 4.2 parts of casein for one part of albumin; or, stated in another way, the percentage of total proteins in the form of albumin varied from 19.1 to 19.7 and, in the form of casein, from 80.3 to 80.9. After the ninth month, the casein decreases relative to albumin, or the albumin increases in relation to casein; and the change is quite marked and rapid during the tenth and eleventh months, constituting the closing months of the lactation period studied.

In the case of the mixed milk of numerous herds of cows whose milk was used in cheese making, we have the following results, derived from Table IV:

TABLE XVI. INFLUENCE OF STAGE OF LACTATION UPON RELATION OF CASEIN TO ALBUMIN IN CASE OF MILK USED FOR CHEESE MAKING.

	Proteins, per cent.	Casein, per cent.	Albumin, per cent.	Parts of casein for 1 part of albumin	Albumin : Casein	Percentage of total proteins in form of casein	Percentage of total proteins in form of albumin
April	2.81	2.20	0.62	1:4.4	81.5	18.5	
May	2.91	2.31	0.60	1:4.4	77.5	22.5	
June	3.04	2.40	0.64	1:3.9	79.4	20.6	
July	3.13	2.52	0.61	1:4.1	80.5	19.5	
August	3.25	2.51	0.74	1:4.1	80.3	19.7	
September	3.33	2.68	0.65	1:4.1	80.8	19.2	
October	3.40	2.74	0.66	1:4.2	80.6	19.4	
November	3.47	2.80	0.67	1:4.2	80.7	19.3	
December	3.57	2.90	0.67	1:4.3	81.2	18.8	

The proportion of casein in relation to albumin decreases until July, when it makes a marked increase and then remains quite uniform during the remainder of the season, which extends approximately through the seventh or eighth month of lactation.

(d) Time and Manner of Milking.—Variation in time and manner of milking may, as we have seen, profoundly affect the fat in relation to proteins, the percentage of proteins remaining fairly constant, while the fat may vary greatly. It remains now to see whether such variation of conditions of milking affects at all the relation of casein to albumin. The data in the tables following are derived from Tables V, VI, VII, and VIII.

(i) Morning's and Evening's Milk.—The following data are given as a mere illustration:

TABLE XVII. RELATION OF CASEIN TO ALBUMIN IN MORNING'S AND EVENING'S MILK.

Date	Proteins, per cent.	Casein, per cent.	Albumin, per cent.	Parts of casein for 1 part of albumin	Albumin : Casein	Percentage of total proteins in form of casein	Percentage of total proteins in form of albumin
Dec. 13th, a. m.	3.10	2.20	0.90	1:4.1	80.4	19.6	
Dec. 13th, p. m.	3.25	2.45	0.80	1:4.2	80.0	19.1	
Dec. 20th, a. m.	3.11	2.20	0.91	1:4.2	80.0	19.1	
Dec. 20th, p. m.	3.03	2.19	0.84	1:4.3	81.2	18.8	
Dec. 28th, a. m.	3.21	2.51	0.70	1:4.1	80.8	19.2	
Dec. 28th, p. m.	3.08	2.30	0.78	1:4.1	80.9	19.1	
Jan. 4th, a. m.	3.47	2.85	0.62	1:4.1	80.6	19.4	
Jan. 4th, p. m.	3.58	2.85	0.73	1:4.1	80.0	20.0	

These data indicate that there may be quite marked variation in the relation of casein to albumin in the milk of morning and evening in the case of the milk of the same animal.

(2) Fractional Milkings of Whole Udder.—We have previously seen that the percentage of fat varies greatly in different portions of milk drawn from the same udder, while the total proteins remain fairly constant. Below we present data to illustrate to what extent the casein and albumin may vary relatively under such conditions.

TABLE XVIII. RELATION OF CASEIN TO ALBUMIN IN DIFFERENT FRACTIONS OF MILKING.

Fraction drawn	Proteins, per cent.	Casein, per cent.	Albumin, per cent.	Parts of casein for 1 part of albumin	Albumin : Casein	Percentage of total proteins in form of casein	Percentage of total proteins in form of albumin
First	3.29	2.67	0.62	1:4.3	81.1	18.9	
Second	3.21	2.57	0.64	1:4.0	80.0	20.0	
Third	3.10	2.49	0.61	1:4.1	80.3	19.7	
Fourth	2.97	2.39	0.58	1:4.1	80.5	19.5	
Whole milk of same cow	3.12	2.51	0.61	1:4.1	80.4	19.6	

These results indicate that under conditions which may very greatly affect the relation of fat to proteins, the relation of casein to albumin may be influenced very little.

(3) Milking Separately Different Quarters of Udder.—We have previously seen milk from different quarters of the udder vary in fat content, with little change in percentage of proteins.

TABLE XIX. RELATION OF CASEIN TO ALBUMIN IN MILK FROM DIFFERENT QUARTERS OF UDDER.

Quarter of udder	Proteins, per cent.	Casein, per cent.	Albumin, per cent.	Parts of casein for 1 part of albumin	Albumin : Casein	Percentage of total proteins in form of casein	Percentage of total proteins in form of albumin
Left hind quarter	2.97	2.33	0.64	1:4.0	78.4	21.6	
Left forward quarter	2.94	2.32	0.62	1:4.2	78.9	21.1	
Right hind quarter	2.89	2.31	0.58	1:4.0	80.0	20.0	
Right forward quarter	2.90	2.38	0.52	1:4.1	80.4	19.6	

The relation of casein to albumin differs in the right and left halves of the udder, but, in this particular case, is practically constant in the two quarters of each half.

(4) Milking Same Quarter of Udder in Different Orders Relative to Other Quarters.—The data below illustrate variation of the relation of casein to albumin as the result of milking the same quarter of the udder in different orders with reference to the other quarters.

TABLE XX. RELATION OF CASEIN TO ALBUMIN AS INFLUENCED BY MILKING ONE QUARTER OF UDDER IN DIFFERENT ORDERS.

Left forward quarter of udder	Proteins, per cent.	Casein, per cent.	Albumin, per cent.	Parts of casein to 1 part of albumin	Percentage of total proteins in form of casein	Percentage of total proteins in form of albumin
When milked first....	2.88	2.30	0.58	1:4.5	80.0	20.0
When milked second....	3.00	2.40	0.60	1:4.0	80.0	20.0
When milked third....	2.96	2.36	0.60	1:4.0	80.0	20.0
When milked fourth....	2.91	2.35	0.56	1:4.1	80.0	20.0

The results show simply that in this particular case there is some slight variation of casein in relation to albumin in milk when the same quarter of the udder is milked in different order relative to other quarters.

#### Methods for Calculating Total Proteins and Casein in Milk.

While the relation of fat to casein in cow's milk is a variable one, a relation exists in the case of mixed milk which can be utilized in calculating the amount of casein approximately when the per cent. of fat is known. As a result of the writer's study of the milk of each of fifty different herds of cows during one season (May to October, inclusive), a general relation was noticed between the fat and casein content. In general, it was found that when fat in milk increases 1.0 per cent., casein increases 0.4 per cent. This was found to hold quite satisfactorily when applied in case of ordinary herd milk varying in fat content from 3.0 to 4.5 per cent. In milk with less than 3.0 per cent. of fat, the casein content is usually higher in relation to fat than in milk with more than 3.0 per cent. of fat; while in the case of milk containing more than 4.5 per cent. of fat, the ratio of casein to fat is usually somewhat less than in milk containing less than 4.5 per cent. of fat. Starting with milk containing an average of 3 per cent. of fat and a casein content of 2.1 per cent., milk with 4 per cent. of fat was found usually to contain about 2.5 per cent. of casein. On the basis of these observed general relations, the following rule was worked out: From the number representing the per cent. of fat in milk subtract 3, multiply the remainder by 0.4 and to the result add 2.1. Expressed as a formula, we have:

$(F - 3) \times 0.4 + 2.1 = \text{per cent. of casein}$  (F equals number representing the per cent. of fat in milk).

This formula may give somewhat low results in the case of milk produced after the eighth or ninth month of the lactation period, when the casein is usually greater in relation to fat than during the previous stage of the lactation period.

Applied to samples of herd milk, this formula is capable of giving very satisfactory results, as shown by the following data:

TABLE XXI. CASEIN IN MILK, CALCULATED BY THE ABOVE FORMULA, COMPARED WITH ACTUAL CONTENT.

Per cent. fat in milk	Calculated casein, per cent.	Actual casein, per cent.
3.88	2.45	2.45
4.00	2.50	2.50
4.06	2.52	2.52
4.15	2.54	2.54
4.20	2.56	2.56
4.30	2.60	2.60
4.35	2.62	2.62
4.38	2.64	2.64
4.40	2.65	2.65
4.42	2.66	2.66

For ordinary purposes, where strict accuracy is not required, the rule can be used quite satisfactorily when applied to herd milk within the limits specified, and comparatively little commercial milk goes outside of these limits.

This method of ascertaining the amount of casein in cow's milk can be found especially useful in connection with infant feeding in cases where it is desired to know approximately the amount of casein in cow's milk. In connection with the feeding of top milk, the following use can be made of the method: Before the cream is allowed to rise, the milk to be used can be sampled and examined for fat by the Babcock test. From the percentage of fat thus found the amount of casein can be calculated. And very nearly this percentage of casein will be present in the top milk. Then, if the relation of fat to casein in the top milk is desired, the fat can be determined directly by the Babcock test. This simple procedure, involving a fat test of the whole milk before creaming and of the top milk after creaming, will enable the specialist in infant feeding to obtain a control over his work which he cannot otherwise have.

#### Summary.

1. Extent of Data.—The study of the conditions affecting the proportions of fat and proteins in cow's milk, as embodied in the preceding article, is based upon the following data: (1) 300 analyses of the mixed milk of numerous herds, obtained at cheese factories, such as is common in the dairy regions of New York State. (2) 650 analyses of milk of 50 separate herds of cows, covering a period of about six months. (3) Several thousand analyses of milk of individual cows, representing seven different breeds of cows (American Holderness, Ayrshire, Devon, Guernsey, Holstein-Friesian, Jersey, Shorthorn), covering for each individual several lactation periods and an aggregate of about 100 periods of lactation.

2. General Range of Variation in the Percentages of Fat and Proteins in Milk.—(1) In single milkings of individual cows, the fat varied from 2.25 to 9.0 per cent.; the total proteins, from 2.19 to 8.56 per cent.; the casein, from 1.59 to 4.49 per cent.; and the albumin, from 0.31 to 5.32 per cent. The highest percentages are found in the case of cows far along in lactation. (2) In the case of individual herds of cows, such as are common in this State, the fat varied from 2.90 to 5.50 per cent.; the total proteins, from 2.31 to 3.71 per cent.; the casein, from 1.79 to 3.02 per cent.; and the albumin, from 0.41 to 0.97 per cent. (3) In the case of milk consisting of a mixture of the milk of many different herds of cows, the fat varied from 3.04 to 4.00 per cent.; total proteins, from 2.53 to 3.76 per cent.; casein, from 1.93 to 3.00 per cent.; and albumin from 0.47 to 0.88 per cent.

3. Conditions Affecting Variations of Fat and Proteins in Milk.—The following conditions are discussed as those of special prominence in causing variations of percentages of fat and proteins in milk: (1) Individuality; (2) breed; (3) stage of lactation; (4) food; (5) season; (6) time and manner of milking, including fractional milkings, milk from different quarters of udder, and relative order of milking a quarter of udder.

4. Conditions Affecting the Relation of Fat to Total Proteins and to Casein in Milk.—(1) The breeds studied fall into two general groups; in one case, the ratio of fat to proteins is relatively high (Guernsey and Jersey); in the other, relatively lower. Individuals of the same breed may vary considerably in this respect. (2) The ratio of fat to proteins is very uniform through the lactation period, until about the ninth month, when the total proteins increase quite rapidly in relation to fat. The ratio of fat to casein is very uniform throughout the entire period of lactation, there being a slight increase of casein in relation to fat about the ninth month. (3) Variations in composition of milk due to manner of milking affect the fat more or less extensively, but the proteins very little.

5. Conditions Affecting the Relation of Casein to Albumin.—Albumin in milk varies quite widely in relation to casein. The ratio varies (1) with different breeds, (2) with different individuals of the same breed, (3) with time and manner of milking. (4) The relation is quite uniform during the first eight or nine months of lactation, after which the albumin increases relatively more than the casein.

6. Method for Calculating Amount of Casein in Normal Milk.—In the case of herd milk containing 3.00 to 4.50 per cent. of fat, the following formula for calculating the amount of casein has been found to give in most cases quite satisfactory results:

$(F - 3) \times 0.4 + 2.1 = \text{per cent. of casein in milk}$   
(F equals number representing the per cent. of fat in milk).

#### GONORRHOÆAL RHEUMATISM CURED BY SEMINAL VESICULOTOMY.

BY EUGENE FULLER, M. D.,  
New York.

Visiting Surgeon, Genitourinary Division of the City Hospital, etc.

In December, 1904, I originated the idea of trying to cure gonorrhœal rheumatism in the male through the employment of the operation I had devised of seminal vesiculotomy, and the first gonorrhœal rheumatic patient I operated upon was at the City Hospital in December, 1904. The result in the first and experimental case was a brilliant success. In February, 1905, I operated upon my second City Hospital case of gonorrhœal rheumatism, the result being a complete cure.

In an article entitled *The Relation of Gonorrhœal Rheumatism to Seminal Vesiculitis and Its Cure by Seminal Vesiculotomy*, published in the *Annals of Surgery*, June, 1905, those two City Hospital cases were reported, together with two other cases from my service at the Postgraduate Hospital, making in all four cures out of the four cases so far operated on. In explanation of my early study of this subject I will quote from my opening remarks in the article just alluded to in the *Annals of Surgery*:

As it was but five months ago, namely, in December, 1904, that the idea occurred to me to try to cure gonorrhœal rheumatism by the operative method I am now reporting, it is only since then that I have been actively investigating these cases from the standpoint of the male subject; and my special clinical study has been to try to determine whether the systemic infection in these cases seemed to enter from any special focus, or from the general mucous surface. I am as a result strongly of the opinion that the systemic infection in the male usually

enters from a special focus, and that that special focus is represented by a seminal vesiculitis. In support of this assertion, I have investigated fifteen cases of gonorrhœal rheumatism in the male. Six of these cases are from my private practice and nine from my practice at the City and Postgraduate Hospitals. In twelve of these the only existing genitourinary lesion was in the seminal vesicles, namely, seminal vesiculitis. In one there was a marked seminal vesiculitis and a subsiding inflammation of the mucous urethral surface. In two, although the seminal vesicles were not free from some involvement, still, the urethral inflammation seemed to be the chief feature. To further prove my contention, I have been able to subject to my operation of seminal vesiculotomy four out of the twelve cases showing seminal vesiculitis to be the only existing genitourinary lesion. By means of this surgical procedure, all systemic absorption from the seminal vesiculitis has been immediately checked and a resolution of the genital lesion has promptly followed. Almost immediately in all these cases the active symptoms of gonorrhœal rheumatism have wholly disappeared.

Up to date, February 1, 1908, I have performed the operation of seminal vesiculotomy one hundred and one times without a death. Out of this number the operation has been undertaken twenty-three times for the relief of gonorrhœal rheumatism.

In all the twenty-three patients the operation has had a profoundly beneficial effect on the rheumatism. All have left the hospital in a well or greatly improved condition. In all these patients there was of course a seminal vesiculitis to account for the focus from which the systemic absorption originated. Out of the twenty-three cases seventeen patients were cured as a direct result of the operation and were well when last seen. Of the remaining six patients, two got well after the operation and remained so till about a year ago, when each of them contracted gonorrhœa afresh. Rheumatic symptoms then reappeared. Both of these patients were then seen but once with moderate rheumatism, after which all trace of them was lost. Two more patients, after leaving the hospital in a very satisfactory condition, immediately resorted to sexual intercourse. The sexual exercise during the convalescent stage from the operation naturally rekindled the seminal vesicles, and there was a relapse of the rheumatism. In both these cases, however, the rheumatism again disappeared after the effects of the premature sexual exercise had passed off, and these patients are now well. Two very chronic cases relapsed, one after being well eight months after operation, and one after being relieved three months. In both these cases there was a recrudescence of the tenderness and inflammation in the seminal vesicles. They were destitute individuals, and probably exposure and poor living were to blame for the relapse.

In the acute bedridden cases the effect of the operation is most marked. In twenty-four to thirty-six hours the pain in the joints disappears, and by the fourth day the swelling. Some stiffness and some atrophy of the muscles are of course left after the rheumatic process has disappeared in these acute cases, requiring massage and passive movement.

In the chronic cases pain disappears in a week or ten days, and at the end of two weeks massage can be prescribed. In the very chronic cases it may take two to three months of massage and exercise to limber up the joints which have been robbed of their function. In fact, one has the same problem in these cases which the surgeon has after resolution from a fracture of long standing. It is well known that in chronic gonorrhœal rheumatism massage and

manipulation make matters worse, whereas in these cases convalescent after seminal vesiculotomy such treatment is beneficial, because there is no longer the systemic absorption of the toxine.

In many of the chronic cases the preceding gonorrhea was so remote an affair that the existing rheumatism had supposedly had no connection with it. In these cases the diagnoses of uric acid, chronic rheumatism allied to the so called inflammatory form, arthritis deformans, gout, neuritis, and neuralgia had been made to account for existing conditions.

The physician or orthopaedic surgeon rather than the genitourinary surgeon had been consulted by most of these sufferers.

One point I have noticed after operation in quite a number of these cases is that in the third week after operation there may be a mild and temporary recrudescence of the rheumatic symptoms, whereas in the two weeks immediately after operation there had been a complete recession of all such symptoms. Such recrudescence, I take it, is due to a somewhat premature closure of the tract of the incision before a complete elimination by drainage of all the toxins has taken place. In all such cases I have been able to demonstrate, by palpation, with the finger tip introduced at the rectum, considerable remaining tenderness and tumefaction in the region of one or both seminal vesicles. By further rest, together with tonics and attention to nutrition, such remaining tenderness and tumefaction will spontaneously disappear in most instances, provided the seminal vesiculotomy has been thoroughly performed. In case there should not be a spontaneous disappearance it may be necessary to open the tract of the wound and reintroduce the drainage tubes, keeping these same reintroduced tubes in place till all question of their necessity has disappeared. I have never found it necessary to reintroduce the drainage tubes in any of my cases of gonorrhoeal rheumatism, although on two or three occasions I have had to do so in connection with my seminal vesiculotomies, undertaken for the relief of other ailments.

During my December, 1907, and January, 1908, service at the City Hospital I have successfully performed seminal vesiculotomy eight times for the cure of gonorrhoeal rheumatism. For the collection of this large amount of material in so short a space of time I am under much obligation to Dr. Mitchell, who was my house surgeon for that period. A brief detail of the histories of these cases is as follows:

CASE I.—H. L., age twenty-two; December, 1907, helpless and bedridden, owing to gonorrhoeal rheumatism involving left leg, hip, and thigh. The symptoms were acute and severe. He had been confined to bed four months following a gonorrhea which he had contracted five months before. There was a marked seminal vesiculitis, but no other genitourinary lesion. Seminal vesiculotomy was performed. In this case there was some bleeding twenty-four hours after the operation, for which the incision was partially reopened and repacked. Following this reopening there was some urinary leakage through the wound. This case now, seven weeks after the operation, is entirely well of all trace of rheumatism. There is a slight stiffened state of the hip, but this is rapidly disappearing as a result of massage and of walking about. The resolution in this case was somewhat tardy, probably due to the repacking of the wound and the temporary urinary leakage. Patient is now ready to be discharged.

CASE II.—P. L., age twenty-three; December, 1907, very acute febrile case of gonorrhoeal rheumatism involving both wrists, left hip and right knee. These joints were

very much swollen and very tender. Patient was in bed and unable to move, and had been suffering from this acute attack about one month. This was his second attack. His first one, which had been very tedious, had been three years ago, following a gonorrhea. Previous to the present attack he had had a urethral discharge, but whether this was a reinfection or relapsing in character was not clear. Examination showed the present lesion to be a seminal vesiculitis. Seminal vesiculotomy was performed, followed by a very quick subsidence of all his rheumatic symptoms. In three days all active evidence of the rheumatism had disappeared. Four weeks after the operation the patient left the hospital to sail for Europe. He was completely well except for a slight stiffness of the right wrist. This was rapidly disappearing as the result of active use of the part.

CASE III.—V. A., forty-five years of age; December, 1907. This patient entered the hospital owing to trouble in connection with his left knee, which he had had apparently for four months. The knee was the seat of a hard, inflammatory tumefaction consisting of an exudation. This exudate had caused complete ankylosis. The joint was tender to deep pressure, and much pain and tenderness resulted when the weight of the body was put on the joint. The patient gave a past history of several gonorrhoeas or relapsing urethral discharges. His sexual function was also impaired. At the time he entered the hospital he felt that he had no gonorrhea or urinary inflammation. Medical and orthopaedic form of treatment had been tried with no beneficial effect, and the patient was transferred to my service. Examination showed that he had a chronic seminal vesiculitis, especially in connection with the right sac, the lower portion of which was enveloped in a sclerous infiltration. Seminal vesiculotomy was performed, the sclerous infiltration cut through, and the sacs freed from adhesions and freely incised. Painful sensations quickly left the joint after the operation, followed more slowly and gradually by a resolution of the hard exudate. With the disappearance of the exudate the joint motion has gradually returned. Now the patient walks about without pain and with much movement in the joint, and this movement is increasing rapidly.

CASE IV.—J. S., thirty years of age. Operated on early in January. Chronic gonorrhoeal rheumatism of eight years' standing. Both knees, hips, spine, and neck were involved. Back was bent, no mobility to spine, and but very little motion to neck. He had been on crutches for a year before operation. Got his first gonorrhea nine years ago and a second attack four years ago. Both seminal vesicles were thickened and embedded in a periseminal vesicular sclerosis. Seminal vesiculotomy was performed five weeks ago. The thickened sclerosed tissue surrounding the seminal vesicles was cut through on each side and the seminal vesicles were freed from surrounding adhesions, after which both sacs were freely incised, packed with gauze, and drainage tubes adjusted. In this case, owing to the chronicity of the lesion, there was no active intraseminal vesicular catarrh, the sac walls being in fact compressed and somewhat atrophic. A few intracellular diplococci were found in a smear taken from the region of the sac cavity. One week after operation patient could move his back and neck quite freely without pain. He is now walking about easily and quickly without crutch or cane. The affected joints are still somewhat stiff and the muscles have not yet recovered wholly from their atony, but those symptoms are rapidly disappearing as the result of massage and exercise.

CASE V.—M. T., December 29, 1907. This case presented an instance of acute gonorrhoeal rheumatism of six weeks' standing. Patient was confined to bed. Both knees and thighs, right wrist, and back were involved. The knees and wrist were very much swollen. Patient was thoroughly helpless and in great pain. He gave a history of gonorrhea eleven years ago, three years ago, and three months ago. The seminal vesicles were markedly sclerosed and evidently recently reinfectured. This was his first attack of rheumatism. Seminal vesiculotomy was performed. Three days after the operation patient was wholly free from pain, and by the end of four days all swelling had disappeared. He could then move his back and legs and wrist without discomfort. In this case at the end of two weeks after the operation there was a slight recrudescence of the pain in

<sup>1</sup> Cases III and IV, reported at the Session of the American Academy of Medicine, Philadelphia, 1908.

the joints due to the premature closing of the outside wound, thus checking all drainage. Before the fourth week, however, this recrudescence had disappeared, leaving the patient in good order and free from his rheumatism.

CASE VI.—J. L., twenty-three years of age; January, 1908. Patient presented a very acute synovitis of the right knee. The joint was greatly distended and there was marked surface redness and tenderness. No movement of the joint was possible. This condition had persisted for six weeks and had been uninfluenced by rest or antirheumatic treatment. Had had gonorrhœa five months before affection in joint appeared. The gonorrhœa had apparently gotten well in three weeks and so had not been connected in a causative way with the following joint involvement. There was no urethral discharge and the urine was clear. Rectal examination, however, showed seminal vesiculitis, the inflammatory involvement being chiefly in connection with the right seminal vesicle. I did not at first wish to operate in this case, being fearful, owing to the rather slight extent of the seminal vesiculitis, lest the operation would fail to relieve the joint. The patient having seen the benefits of the operation in the preceding cases, begged for the operation, and I accordingly performed seminal vesiculotomy. In three days all pain, swelling, and inflammatory evidence had disappeared from the knee. In fact, on inspection the right knee looked exactly as the left. In this case also at the end of two weeks there was a slight and temporary recrudescence of the rheumatism, the right wrist becoming a little stiff. This, however, shortly disappeared, leaving the patient well.

CASE VII.—J. S., age thirty-one; January, 1908. This case was to me one of the most interesting of the series. For three months the man had been unable to move his legs or thighs. He lay perfectly helpless on his back. He had first felt his rheumatism one year before, and from that time it had been gradually getting worse. Two years ago he had had gonorrhœa, but stated that he had gotten wholly over the disease in two months and had never after had occasion to think of it. He had taken all sorts of antirheumatic remedies, and had been treated by orthopædic surgeons, all to no avail. Rectal examination showed a marked old seminal vesiculitis with much periseminal vesicular inflammatory involvement. Seminal vesiculotomy was performed, and in three days he could move his legs and thighs freely. At the end of three weeks, on being let out of bed, he ran about the ward briskly with no discomfort. This was remarkable, as in most such cases the joints are left stiff for a time after the rheumatism has disappeared, necessitating massage.

CASE VIII.—J. S., age twenty-seven years of age; January, 1908. This patient had gonorrhœal rheumatism in both ankles and knees. He was not bedridden, but walked with great difficulty with a stick. Both ankles were somewhat swollen. He had been so affected one month. Two months before he had contracted gonorrhœa. This was apparently his third attack of gonorrhœa. The urethral discharge still persisted at this time. A chronic seminal vesiculitis existed which showed evidence of recent reinfection. Seminal vesiculotomy was performed, followed by a quick disappearance of the rheumatic symptoms. This patient at the time of this report is ready to leave his bed.

Before performing seminal vesiculotomy on any of these patients I have endeavored to exclude tuberculosis as a complicating element through the employment of the Calmette and tuberculin tests. Had these tests in any instance indicated tuberculosis I would have refrained from operation.

From the results obtained in the comparatively large number of cases operated on I now feel that the efficacy of this form of treatment is established.

My preceding articles bearing on seminal vesiculotomy are as follows:

## THE KIDNEY IN ACUTE INFECTIONS.\*

By JOHN B. HUBER, A. M., M. D.,  
New York,

Visiting Physician to St. Joseph's Hospital for Consumptives, New York City, etc.

An incomplete list of the diseases with which the kidney may be related in infectious processes would include scarlet fever, typhus and typhoid fevers, malaria, pneumonia, diphtheria, influenza, acute rheumatism ulcerative endocarditis, septicæmia, erysipelas, intense and diffuse erythematæ, small-pox, measles, varicella, parotitis, tonsillitis, meningitis, acute tuberculosis, dysentery, yellow fever, and bubonic plague. It is not possible, in a brief paper, to consider these affections in detail; I can but prepare in some sort a composite picture. And in doing so I must paint with a broad brush.

To begin with, the kidneys are more subject than are some other organs to pathological influences. Because of their anatomical position they must bear an enormous amount of punishment; and they have comparatively little means of effective rebellion. Their texture is unusually intricate and delicate; and therefore so much the more in danger of breaking down under great and undue pressure. When the lungs are diseased they have a fairly large vent through which pathological material may be emitted; an outraged stomach may easily enough empty itself; any abuse of the alimentary tract may be very thoroughly purged away. But the kidneys cannot so easily meet the strains put upon them. They are imbedded in a mass of fat, in a region so shut off that examination of them by the clinician is most difficult and oftentimes impossible. We cannot directly examine them as we can the blood, the larynx, or the bladder; we cannot, in most cases, apply to them the physical tests we use in examining the heart and the lungs. Their only vent is the ureters; the urine which they excrete should and does give us much diagnostic information. Yet we are being surprised and not a little mortified when Cabot and others demonstrate the very wide discrepancy there had been between the diagnoses based upon urinary findings during life and the evidences revealed on the autopsy table.

The function of the kidneys under normal conditions is to eliminate from the blood substances which have been excreted elsewhere throughout the organism in the processes of metabolism. In the infections the products of inflammation are for the most part existent in the blood before they reach the kidneys. In addition to the heavy work of dis-

\*Read in a symposium before the New York Urological Society.

posing of these, these suffer, as must all the others, either from bacterial invasion or from the effects of the toxins evolved by the bacteria. The degree of degeneration or destruction of kidney tissue will also vary according to the biological characteristics of the given specific agency. The tubercle bacillus seems comparatively innocuous with regard to this organ; the streptococcus, on the other hand, works extensive necrotic changes.

The internal secretion of the kidney (which contains the renal juice) should be considered. The field of internal secretions is a new one; and the near future may prove it to be very broad and fertile. The point here is that under abnormal conditions the kidney either does not secrete the renal juice, or the secretion of the latter is modified; and thus the organism suffers from the deprivation of whatever benefits the juice exerts. We are not at all sure in what matter uræmia comes about. The prevailing belief has been that it is due to the retention of excrementitious matters in the blood, which the diseased kidney cannot eliminate. Yet there are many objections to this belief. And von Noorden, though he does not maintain the view, thinks it possible that uræmia really supervenes when this kidney function of internal secretion is held in abeyance. (Nephrectomized dogs died sooner than when the ureters were ligated; the kidney secretion could nevertheless, in the latter case, get into the blood. And the nephrectomized dogs lived longer when renal juice was injected into them.)

The symptomatology of kidney involvement is classic: Chilliness and rigors; pain in the back; fever, sometimes absent, sometimes high, especially in children; a high tension pulse; the aortic second sound accentuated (evidences of a heart hard at work). A dry, pale skin; no sweat; possibly acute uræmia; convulsions sometimes in children; hemorrhagic retinitis and papillitis; puffy eyelids; oedema of the extremities and perhaps of the lungs and the glottis; pleural effusion, possibly dropsy.

The specific gravity of the urine will vary inversely with the quantity passed; generally it is high, in the beginning at least. This fluid is highly colored, from a smoky hue to that of deep porter; it may be bloody. The sediment is abundant; albumin, epithelial, hyaline, renal tube casts and pus cells are to be found. Bacteria may be present. The acidity is high; the urea is at first abundant and later reduced. There may be suppressed or scanty urine. Such, in general terms, are the evidences of a kidney suffering from an acute infection. The symptoms may be very marked, without indicating great danger to the organ; on the other hand grave lesions will result, it would seem, with very few signs to manifest them. In certain infections characteristic things are found: In typhoid fever, for instance, the bacillus may be abundant in the urine, even for years after the attack; the diazo reaction may manifest the disease. In septicæmia pus and necrotic detritus may be forthcoming; on the other hand, there may be extensive necrosis which will not be evident, for the reason that the broken down tissue will find no outlet in the pelvis. A bloody urine is found even in grippe; it is not uncommon even in scarlet fever, smallpox, and yellow fever. We may, from urinary examination, infer pyæmic foci in cranial bones. A diphtheritic

membrane may develop in the pelvis. In acute dysentery the colon bacillus, which ordinarily seems innocuous (except, as Metchnikoff thinks, to hasten senility), may take on virulent properties. Like the typhoid bacillus, it may be found abundantly in the urine.

The pathological changes wrought in the kidney in infectious diseases may be slight and evanescent; or they may be extensive and permanent. The glomeruli become swollen and congested; and thus the circulation in them is obstructed. Detritus extends Bowman's capsule. The nutrition of these most delicate structures is interfered with. Yet the convoluted tubules seem to suffer most, since the tufts eliminate fluids, leaving the tubules to cope with the more concentrated blood which afterward passes through them. In these tubules the epithelial cells suffer granular or fatty degeneration. There may be such interstitial changes as cellular infiltration in and about the parenchymatous structures. The general organ suffers because of retention in the blood current of waste products and the infective material which the affected kidney does not eliminate.

Our ideas of diagnosis in renal disease have of recent years been not a little disturbed. A decade ago Councilman observed that "the chemical and microscopical examination of the urine, important as it is, does not give any sure indication as to the character of the renal lesions." Upon this hint Cabot investigated; Emerson, of Johns Hopkins University, and others also worked upon the same lines. Cabot holds that albumin and casts alone never prove the presence of nephritis; that by their appearance in the urine we can never estimate the anatomical condition of the kidney. Moreover, most estimates of urinary solids, phosphates, chlorides, sulphates, and especially urea, are a waste of time. The most reliable data about the urine are those most quickly obtained—the twenty-four hour quantity, the specific gravity, and the color. The iconoclastic Cabot divides disturbances of renal function into three sorts; renal irritation, renal insufficiency, and nephritis. He submits that the term irritation is vague; it means, no doubt, the equivalent of a mild inflammation. Many things, including fevers, may bring it about; it may be evidenced by albumin, casts, blood, pus, and renal epithelium, just as those things are held to indicate an acute nephritis. But Cabot's distinction is that if these urinary abnormalities disappear in a few days we have simple irritation; and that such a temporary change in the urine is perfectly consistent with normal kidneys, according to autopsy findings. And we should add that urinary examinations should be continued during weeks; that the search for bacteria should not be neglected; and that if the abnormalities persist through a number of weeks the meaning is that pathological changes have supervened in the kidney structure.

In renal insufficiency the kidney cannot excrete the products of nitrogenous metabolism, water, and inorganic salts; the urine is suppressed and visceral phenomena, dropsy and heightened vascular tension leading to cardiac hypertrophy and dilatation supervene. Cabot here likens the heart and the kidney to a team, and he declares that a strong heart will triumphantly help through a badly damaged

kidney. The harm done by a diseased kidney, he declares, will depend upon how well the heart can make up for the damage by increased work. If a fair amount of urine is passed we know that the heart is doing well; when the heart and the kidney are both failing the amount of the urine begins to decrease; and then we have evidences of renal insufficiency. I think, however, it is a mistake to rely too much on the heart in infectious fevers; the effect of bacterial and toxic invasion upon the myocardium (as in diphtheria and gripe), is such that sudden death has during the present season been not at all rare.

In acute nephritis, as in certain chronic forms, we must rely more than formerly on the history, the general condition, and the physical signs of all the organs; and less on urinary findings. It was a mistake to consider the kidney as a thing apart in the economy. Cabot declares that thirteen out of one hundred cases of acute nephritis were recognized first on autopsy; one in four were wrongly diagnosed. Eleven were clinically called acute nephritis; but the autopsies showed no corresponding lesion. Emerson's conclusions were much like Cabot's; they were reached from a consideration of over 1,000 cases, with 500 autopsies.

Osler observes that persons rarely die of the serious diseases which they have suffered during life; terminal infections carry off many incurable cases. Such is certainly the experience in hospital wards. He cites Flexner's analysis of 255 cases of chronic renal and cardiac disease, in which complete bacteriological examinations were made at autopsy; excluding tuberculous infection, 213 gave positive and forty-two negative results. Local intercurrent affections are very common; and the majority of cases of advanced arteriosclerosis and Bright's disease evidence at autopsy such bacteria as the *Streptococcus pyogenes*, the *Staphylococcus aureus*, the *Bacillus proteus*, and the gonococcus. Of eighty-five cases of chronic renal disease in which Flexner found bacteria, thirty-eight exhibited general infections.

In my own desultory experience as a coroner's physician a decade ago, I oftentimes had occasion to wonder how the lives of the subjects examined could have continued so long as they did, notwithstanding the extensive destruction of organic tissue which was revealed. I have understood this a great deal better since I heard Dr. S. J. Meltzer's paper on the Factors of Safety, which he read before the Harvey Society. With regard to the renal function we know that life is lived very comfortably after the surgeon removes one kidney. In animals at least two thirds of both kidneys can be removed without serious detriment to life or to the renal function. Moreover, the average quantity of the urine, as well as the normal quantities of its various constituents, may be greatly reduced without any visible detriment. With regard to human beings Meltzer observes: "For a score of years or more, in many of us the kidney is gradually losing some of its valuable material from one cause or another without any symptom, without a reminder sufficient to spoil our pleasure of life or to hamper our activities. Not until that luxurious surplus is approaching its exhaustion do we get a warning.

But then our work is mostly done and our time limit nearly reached."

I shall not outline the familiar treatment when the kidney is involved in infectious fevers, but shall submit but one observation: We are, or at least we have until recently been advised to direct the drinking of as much water as possible; water in unlimited amounts, "gallons of water. The patient can't get too much of it," the idea being to flush the kidneys and thus wash the debris from their tubes, an idea rather fanciful than scientific. Certainly the patient should drink as much fluid as he desired and as he can comfortably dispose of; but to force fluid upon him in unlimited quantities is certainly a mistake. For thus extra and often unnecessary work is laid upon the kidney and especially upon the heart; no doubt the latter has frequently broken down under such a strain. It were better to ease the labor these organs have to do by diaphoresis and hydrotherapy; we had best put as much of the work as possible upon other emunctories. This consideration should hold, I think, except in extensive erythemata, when the skin cannot perform its functions. It were oftentimes well to complement the drinking of water with proctoclysis; though, of course, this would not materially lessen the cardiac and renal strain.

#### NOTES OF THE JUNGLE PLANT (*COMBRETUM SUNDIACUM*).\*

##### *Exhibit of Cases.*

BY W. DUNCAN SILKWORTH, M. D.,  
New York,

Member of the Medical Society of the County of New York.

The various manifestations of chronic morphine and opium poisoning are conditions so well known that further reference to them is not necessary in calling attention to the antioium plant which has been used with apparent success in the Far East. In passing, however, I should like briefly to allude to the term morphinomania, as commonly used and placed in the same category with dipsomania, which as a disease is almost universally considered incurable. The vast majority of those addicted to morphine would, beyond doubt, discontinue its use promptly were it not for the physical torture which would almost immediately supervene. They use the drug from necessity, not from desire. There are unfortunate cases where neurasthenia or some peculiarity of constitution renders a permanent withdrawal of the drug almost impossible, and to this limited class may be attributed the origin of the term morphinomania, a morbid craving for morphine. In opium smoking, the pipe itself, the lamp, and associations are powerful factors in considering the possibilities of a permanent cure. There are many who, long after they have discontinued the drug, will continue to light each night the small lamp used in preparing the opium for smoking, so that after a few years' use of the drug these are the habits they crave possibly more than the opium itself. A more healthy and humane conception by

\*Read before the New York County Medical Society, February 24, 1908.

physicians of drug addiction will do much toward eliminating the habit and will turn to legitimate channels the thousands of dollars which now fill the pockets of advertising frauds.

A party of Chinese wood cutters were presumedly the first to discover the properties of the drug which is now used extensively as a cure for the opium smoking habit in the Federated Malay States. The plant is a large climber, with a long woody stem often reaching a height of one hundred or more feet. In the *Materials for a Flora of the Malayan Peninsula* it is described botanically by Lieutenant Colonel Sir George King and is shown to belong to the order *Combretum sundiacum*. Sir George Watt, in a dictionary of the economic products of India, mentions two species of the genus as being used in native Indian medicine, but with no details as to their uses or properties.

In preparing the drug, the branches and leaves are chopped into pieces about one and a half inches in length; after drying, the woody portions are separated from the leaves, and both the bark and the leaves roasted, the leaves to a less extent than the bark. Upon completion of this process the two portions are mixed together again.

The infusion is prepared by taking, for example, ten ounces avoirdupois of the roasted drug and mixing with about four gallons of water. This solution is kept boiling for three hours, being loosely covered to prevent too rapid evaporation. The liquid is then strained and is ready for use. I do not believe that a fixed rule for prescribing can be laid down, but in general the method of administration to an opium smoker would be as follows:

Whatever the daily amount of opium the person habitually smokes, that amount is to be mixed with the infusion. The average allowance would be from sixty to one hundred and twenty grains, although beyond doubt a considerable quantity of the alkaloids are not absorbed into the system of the smoker. If, for example, one hundred and twenty grains had been the daily allowance, then two twenty-five ounce bottles of the infusion A and B are used. Into A is put one hundred and twenty grains of burnt opium (that is prepared the same as if for smoking). From the bottle A one and a half ounces is given to the patient and one and a half ounces from bottle B is put into bottle A. This is repeated each time a dose is taken, usually three times a day. Bottle A maintains its bulk, although continually decreasing in its opium contents until bottle B is exhausted. At the end of this course a second treatment is given, beginning with about one third the initial amount of opium used, and upon completion of this the patient should be cured. With twenty-five ounces in the bottle and one and a half ounces at each dose, there would be about sixteen doses in each bottle. Each dose would represent a decrease of one sixteenth of the total amount of opium left from each succeeding dose up to the seventeenth dose on the sixth day, or until bottle B is exhausted. There would then be no further change to the thirty-second dose, when the entire one hundred and twenty grains would have been taken and the contents of the two bottles exhausted.

The remedy, while not a panacea, seems to offer

the best medium of reduction thus far given to the profession, and while my experiments have been confined solely to the practical demonstration of the plant, I am led to believe that there may be present in the remedy an active ingredient, antiopium in its properties. The burnt opium in gradually decreasing doses certainly plays an important rôle in the treatment, but this alone, or in combination with any other form of medication heretofore known, has been, on the whole, unsatisfactory.

Both physician and patient must work together in harmony, and the suffering incident to the discontinuance of a powerful drug must be mitigated as much as possible, if permanent results are to be obtained.

I wish to acknowledge the great assistance which was given by the Rev. W. E. Horley, of the Methodist Episcopal Mission at Kuala Lumpur, and L. Wray, Esq., I. S. O., whose paper in *The Journal Federated Malay States Museums* has formed the basis of my investigations. The Rev. Mr. Horley writes me that "thousands have been cured, but, alas, many have returned to the drug. Will power and the grace of God are needed in conjunction with the remedy."

CASE I.—Mrs. M. had used the drug continuously for sixteen years, the habit having been acquired at the age of fifteen; the daily amount of opium taken by the patient varied from sixty to one hundred and twenty grains. No other drug or stimulant had been used.

The condition of the patient was critical, melancholia was pronounced, accompanied by a state of mental and physical collapse. Not being acquainted with the action of the new remedy, it was considered best to first improve the general condition of the patient, and a short preliminary treatment under the usual methods was given, during which the daily amount of the drug was somewhat reduced. The remedy was then prepared and administered as follows:

The initial amount of the solution prepared was equivalent to fifty ounces; with twenty-five ounces of this was dissolved one hundred grains of burnt opium; three doses were given a day, about one and one half ounces at each dose, the remaining twenty-five ounces being used to dilute the first solution in like proportion as each dose was taken. The reduction of the opium during the first five days amounted to about one sixteenth of the total amount at each dose. From the fifth to the seventh day the reduction remained constant. During the eighth day the dose

being necessary to relieve headache, accompanied by restlessness and to frequent attacks of sneezing; the distressing gastrointestinal symptoms so often connected with the withdrawal of opium or morphine not occurring during the entire treatment. Improvement in condition on the ninth day being apparent, the initial dose was again resumed and the course completed on the tenth day. The symptoms, however, not having sufficiently abated, a second

the initial amount of opium. The reduction was then continued at the same rate until the patient was free from further inconvenience.

I am indebted to the Rev. W. E. Horley, of the Methodist Episcopal Mission at Kuala Lumpur, and L. Wray, Esq., I. S. O., for the information that Mrs. M. was the first patient to be treated with the new remedy. Mrs. M. was the first patient to be treated with the new remedy, and she was the first patient to be treated with the new remedy. The treatment was given to her as an absolute slave to the habit, having been suffering from it for many years, and she was the first patient to be treated with the new remedy.

CASE II.—Mrs. F. had used the drug for many years, the habit having been acquired at the age of fifteen, and she was the first patient to be treated with the new remedy.

of the treatment with apparent success, but for reasons not clear to me, relapsed, although stoutly denying the same.

CASE III.—Mr. M. first acquired the opium smoking habit in Boston, fourteen years ago. After two years of smoking shifted to morphine subcutaneously, which has since been used continuously in amounts varying from fifteen to sixty grains in twenty-four hours. A preliminary treatment was given and with the intelligent cooperation of the patient, the drug was reduced from fifteen grains subcutaneously to four grains internally. One hundred and twenty grains of burnt opium were then dissolved with twenty-five ounces of the solution and three doses were given a day, following closely the procedure of the first case. Three courses were given and the treatment voluntarily discontinued.<sup>1</sup>

CASE IV.—Mr. H. L. Opium smoking habit of fourteen years' duration. General condition fair for this class of case. Some emaciation and quite marked nervous twitching. Patient used about eighty grains of opium in twenty-four hours. Under a short preliminary treatment the drug was reduced slightly and the general condition somewhat improved. Sixty grains of burnt opium were then dissolved with twenty-five ounces of the solution. Three doses were given a day, one and a half ounces at each dose, with no variation in the regular scale of reduction up to the sixth day. The number and amount of the doses were then voluntarily decreased by the patient and finally discontinued on the twelfth day. During the entire treatment no other drug or stimulant was used. As in the former cases, attention to hygiene and diet were insisted upon.

CASE V.—Mr. E. W. Morphine habit of seven years' duration. Daily amount nine grains internally. Regular toxic symptoms with very pronounced pallor and emaciation. Tonics were given, and with the earnest cooperation of the patient the drug was reduced from nine grains to four grains a day. The treatment was administered as in the previous cases, two courses completing the cure, covering a period of twenty-one days.

CASE VI.—Mr. E. M. Morphine habit of eight years' duration. Daily amount eight grains internally. Condition fair. The regular course of treatment was followed and the drug reduced to two grains in twenty-four hours. Two courses of the treatment completed the cure, which has just been accomplished within the past few days.

124 EAST SIXTEENTH STREET.

## EXTRACTION OF CATARACT IN THE CAPSULE.\*

BY WILBUR B. MARPLE, M. D.,  
New York,

Ophthalmic Surgeon, New York Eye and Ear Infirmary, etc.

If any one supposes that the writer accepted the invitation to present the following paper because he poses as an advocate of the extraction of cataract in the capsule as a routine practice, he wishes to correct the misapprehension at once. He never has done it, and doubts if he ever will, except in cases in which it was plainly indicated in the manner to be brought out below.

It is now thirty years since Pagenstecher advocated the extraction of cataract in the capsule in selected cases, and more recently Major Smith, of Jullundur, India, has done a similar operation as a routine procedure.

The technique of Pagenstecher's operation is as follows: Strict attention to asepsis is given and cocaine is employed. He syringes out the lachrymal canal with a sublimate solution, 1 in 5,000, before the operation, and, being ambidextrous, operates on the right eye with the right hand and on the left eye with the left, standing at the head of the patient.

who is lying in bed. The section is made upwards in the sclerocorneal margin, so that it lies wholly in corneal tissue, with more or less of a conjunctival flap. The position of the section in the cornea favors rapid healing, and the conjunctival flap tends to bring about early closing of the wound. As Pagenstecher says, however, it is of more importance that the section is made with a steady hand and a sharp knife, and that it shall not become infected than that its location is accurately adjusted.

The section should be large enough in each individual case to allow the easy extraction of the lens. When the lens is extracted in the capsule, the section, above all, must not be too small, yet it should never be larger than one third of the corneal circumference. (The writer generally makes the section two fifths of the corneal circumference.) Morgagnian cataracts, of course, slip out through smaller sections. Pagenstecher operates with a small knife, selecting one with the back not too thick. He thinks that a knife with too thick a back bruises the tissues at the points of puncture and counterpuncture, and that this may delay healing and predispose to infection. He uses a Weiss knife with double edge, but admits that it bends easily.

He always does an iridectomy, since the vision is practically the same whether or not there is a coloboma, and he would rather excise the iris than expose a single case to the danger of a prolapse. After freeing the pillars of the coloboma, an attempt is made to expel the lens by making pressure through the lower lid against the cornea below, while the scleral margin of the wound above is gently pressed backwards with the spoon. Sometimes this manoeuvre succeeds in expelling the lens. If it does not, he introduces the spoon rather steeply behind the upper border of the lens; the handle is then depressed and the spoon is gently advanced, but not beyond the posterior pole of the lens. The assistant now makes gentle pressure upon the lower corneal margin with a specially constructed glass spoon or pusher, sliding this upward over the cornea with light continuous pressure, thereby pushing the lens upward into the wound. In this manner the spoon in the operator's hands serves more the purpose of an inclined plane upon which the lens is pushed out, than of a traction instrument; at the same time it holds back the vitreous humor and prevents it from escaping. Only when the zonula is pretty firm and when the lens by moderate pressure from without cannot be entirely delivered should the operator push the spoon further to the lower border of the lens, seize the latter from behind, and extract the cataract, while the assistant makes gentle pressure upon the cornea.

Pagenstecher thinks that when correctly done, in a proper case, it is a more conservative operation than when the capsule is opened and pressure is made upon the globe, expelling the nucleus and removing the cortex.

He flushes the conjunctival sac with a sublimate solution, 1 in 5,000, before and after the operation, covers the eye with sublimate gauze, then with cotton wet in the sublimate solution, and finally with a bandage. When there is chronic conjunctivitis or a recently cured dacryocystitis, he employs a modified "open treatment." He covers the eye with

<sup>1</sup>Mr. M. has reported his own story to the society.  
\*Read, by request, in a Symposium on "Cataract Extraction" before the Section in Ophthalmology of the New York Academy of Medicine.

a moist sublimate compress, which is changed every two hours, or three times a day; at the same time he washes out the eye with the above mentioned solution. Most ophthalmologists have, of course, long since given up the use of sublimate solutions for irrigating the conjunctival sac before and after cataract extraction. I have used for a good many years a sterile normal salt solution.

He has been surprised at the very slight irritation which attends the healing in these cases. When the eye is bandaged he uses a form of coquille, as we do the mask, and as soon as the wound is closed he keeps on the coquille alone. (I myself have found in not a few cases that removal of the bandage within three or four days after the wound has closed, leaving the eye protected simply by the mask, has been followed by a more rapid clearing up of the redness of the eye.)

It may be instructive to bring out the indications for extraction in capsules by briefly referring to one or two cases which have come under my observation.

CASE I.—August 19, 1902, I operated at the New York Eye and Ear Infirmary upon an old lady who had an hypermature cataract in the right eye. Careful examination previously showed that there was no sign of luxation of the lens. When an attempt was made to do a capsulotomy, the cystotome merely pulled the lens bodily after it, but did not lacerate the capsule. At the same time, vitreous presented in the wound. An iridectomy was made, the spoon was introduced, and a large brown lens was extracted with the loss of scarcely any vitreous. The result was excellent, and the patient was discharged in ten days. I thought at the time that the reason for the complication was a dull cystotome, but the same accident happened to me again in a similar case when the cystotome was known to be in perfect order. It was evident that the lens was so hard, its capsule so adherent, and the zonula so atrophied, that the cystotome merely dug into the hard lens and pulled it along after it.

These lenses may not infrequently be removed in the capsule without the introduction of a cystotome or spoon into the eye, and a cautious attempt to do this should generally be made. In several cases I have succeeded in extracting the lens in this manner.

CASE II.—On June 23, 1905, I operated at the New York Eye and Ear Infirmary on the right eye of an adult male for shrunken cataract. After a small section, an unsuccessful attempt was made to express the cataract. I then endeavored to seize it with capsule forceps, but this attempt also failed. A small iridectomy was then done, and pressure and the forceps again failing, I cut through the zonula with a Graefe knife. The spoon was then introduced, and the cataract was extracted after one or two unsuccessful attempts, with the loss of a very little vitreous. The reaction was slight, and the patient was discharged in two weeks with a good result.

These two cases illustrate one of the indications for Pagenstecher's operation, viz., hypermature cataracts. Under hypermature cataracts belong, of course, Morgagnian cataracts, and those that are shrunken and chalky, as in Case II.

CASE III.—On June 30, 1904, I operated at the Infirmary on the left eye of a man. The patient had been suffering for a long time with a cataract which was gradually increasing without rupture. The vision had been long almost extinct. He was a man of middle age, and had been an electric bell without the bell. He would hold this up to his face so that the hammer would come in contact with the bell, when the current in the bell was turned on. This was the "trick sign," and a few competent demonstrators told me that it was quite painful. So far from curing the condition, it appeared to aggravate it in a surprisingly short time, for ten days before he had been able to attend to his business, but now had to be led

to my office. Both lenses were opaque and swollen; he saw fingers at five feet in one eye and at one foot in the other. In addition, the left lens was partially dislocated and there was a tremulous iris. It is easy to imagine the force with which this instrument "massaged" the eye.

Operation.—Left eye. After the section and iridectomy, vitreous presented. I then introduced a wire loop back of the lens and almost lifted it out, but it slipped back. This necessitated a second introduction of the loop, and this time the lens was extracted without the loss of vitreous. His vision with correction was finally 20/15, though on the fifth day I had to cauterize a portion of the wound. The anterior chamber was slow in closing.

This case illustrates another indication for extraction in the capsule, viz., dislocated cataracts, and presentation of vitreous after section or iridectomy. A further indication for the operation, according to Pagenstecher, is furnished by cataracts which have formed in eyes that have had chronic iridochoroiditis with occlusion of the pupil. I have recently, however, operated in such a case satisfactorily with capsulotomy and subsequent needling.

#### Contraindications:

1. Even when from its character a cataract is suitable for this operation, it is contraindicated if, after section and iridectomy, the tension of the vitreous is high or the patient is unruly.

2. In cataracts which have been ripened by Förster's method, it is best not to attempt to extract in the capsule, since the latter is very tightly stretched by the swelling of the lens masses and is apt to rupture if such an attempt is made.

3. Cataracts which have been ripe only a short time, and have ripened quickly, as in the course of a few months, should not be operated on after this method, as the capsule has not attained sufficient strength compared to that of the zonula. These cataracts are swollen, and are said to be in the *stage of imbibition*.

Pagenstecher says he regrets that he cannot operate on all cataracts in this manner, and that the only reason he does not is on account of his conviction that the majority of cases are not suitable for it, inasmuch as the capsule is apt to rupture and part of it remain behind in the eye.

#### Advantages of the Operation:

The vision secured in this manner is permanent, for there is no capsule left behind to subsequently wrinkle and cause deterioration of sight. The pupil is clean, the best possible vision is secured, and a secondary operation is not necessary.

#### Disadvantages:

There can be no doubt that loss of vitreous occurs by this method far more frequently than when the capsule is left behind. Pagenstecher operated on seventy-four cases in which the cataract in one eye was hypermature, and in the other eye simply mature. He extracted the first seventy-four with the capsule and the last seventy-four without the capsule.

In passing, it might be noted that of these seventy-four cases Pagenstecher operated fifty-six times on both eyes at one sitting, on practice with the wisdom of which opinions differ. I have never operated on both eyes at one sitting, and it has always seemed to me that Dr. Knapp's position in reference to this was correct. If we operate on both eyes at the same time, the conditions are alike, and

if there should happen to be a break in our chain of asepsis, and infection should take place, both eyes would be lost—an appalling calamity which every operator seeks to avoid. Moreover, during the treatment, we learn a great many peculiarities of the bodily and mental conditions of our patients, which it is of advantage to know at the second operation. If there are any particular circumstances making it desirable to have the two eyes operated on at about the same time, a good compromise is operate on the second eye a week or two after the successful operation on the first.)

Of the seventy-four cases extracted in the capsule there was loss of vitreous in thirty-nine, or in nearly 53 per cent.; while in the seventy-four cases extracted without the capsule this complication occurred in only five, or 6.5 per cent. While he prefers not to lose vitreous, his experience has led him to look upon such loss in extraction in the capsule as an unimportant complication, attended by no further danger to the eye, so long as strict asepsis is observed. There are few observers, however, who agree with Pagenstecher, that this accident is of such trifling significance.

Ray, of Louisville, read at Atlantic City, in 1907, before the Section in Ophthalmology of the American Medical Association, a paper on The Immediate and Remote Effect of Loss of Vitreous in the Operation for Extraction of Cataract. In this paper he has collated the views of a number of operators of skill and experience upon the question whether loss of vitreous at the time of extraction increases the danger of infection. Most operators consider that the vitreous is a perfect culture for microorganisms, and that the probability of infection is greater when the hyaloid is ruptured and vitreous is lost. Ray concludes that loss of vitreous at the time of extraction adds to the danger of primary infection, this danger being irrespective of the quantity of vitreous lost, but dependent largely on the care used in the preparation of the field of operation.

With this opinion the writer agrees in the main, and considers that it is of the utmost importance to observe the strictest aseptic precautions when vitreous is lost. I confess that I am much relieved when, on changing the dressing, I find everything in a satisfactory condition in a case in which I have lost vitreous.

While most operators consider that loss of vitreous predisposes to subsequent detachment of the retina, it must be admitted that Pagenstecher's results do not support such a view. Out of six hundred extractions in the capsule, done by himself and his brother, he met with only one case of detachment of the retina, and this in a myopic eye with extensive choroiditis and fluid vitreous—surely a most excellent showing, according to any method. Moreover, there is some force in what Pagenstecher says, viz., that, as so often happens, one here confounds cause and effect. If an operator happens to do an extraction with loss of vitreous in one or several eyes in which subsequent detachment occurs, he immediately concludes that the loss of vitreous is the cause of the complication, whereas the real cause lies in certain pathological changes in the eye with predispose to retinal detachment, and

this, together with the fluid vitreous or detachment of the vitreous present, at the same time, causes the loss of vitreous during the operation. Moreover, when this complication occurs, the pillars of the coloboma are much displaced and the coloboma thereby is widened. This does not improve either the cosmetic or visual results.

Another disadvantage attending extraction in the capsule is that the resulting astigmatism is greater.

Rupture of the capsule very seldom happens in the ordinary method of operating or when the extraction in the capsule is limited to those cases in which Pagenstecher considers that it is indicated. In one hundred seventeen cases operated on by him, rupture of the capsule occurred only four times.

#### *Management of Prolapse, or Loss of Vitreous:*

If merely a bulging of the vitreous occurs without any actual loss, Pagenstecher says that this usually returns under the pressure of the lids. Until quite recently my own experience agreed with this observation. Some weeks ago I extracted a hypermature cataract in the capsule with iridectomy. There was a small hernia of the vitreous, but no loss. I bandaged the eye, hoping that the vitreous would return, as I had seen it do before. On account of my own subsequent illness, I did not see the patient again for ten days. A condition had arisen which is well described by Czernak: "After the rupture of the zonula the hyaloid yields and the vitreous bulges forward and presses against the wound, causing it to gape. The iris is thus folded between the lips of the wound and incarcerated, whether or not there has been an iridectomy. The coloboma is thus made surprisingly broader and its pillars can be released only with the greatest difficulty, or not at all." This is exactly what had taken place in this case, and the condition was not at all satisfactory. The wound did not close for fully a month. So that if I had a similar case and still found bulging of the vitreous when I changed the dressing, I should excise it.

When there is actual loss of vitreous, Pagenstecher cuts it off close to the wound with scissors curved on the flat. My own observation has been that when vitreous is excised more follows, so that I have usually left the vitreous tags untouched, and generally at the first or second dressing I have found the wound closed.

Sometimes after the loss of fluid vitreous, sometimes when no vitreous has been lost, the eye collapses and presents what Knapp used to call a "squeezed lemon" appearance. In these cases it is always well to gently inject sterile normal salt solution, so as to restore the shape of the globe and thus bring the edges of the wound into apposition. Knapp reported (in his *Archives*, 1899, p. 308) cases treated in this manner, and Andrews also reported cases treated in a similar manner (Knapp's *Archives*, 1900, p. 50).

The writer has a great deal of respect for the conservatism of Czernak, and agrees with his conclusions as to the value of Pagenstecher's work. Czernak says: "In these cases an accurate diagnosis is of the first importance, as Becker has already emphasized in his work on *The Pathology of the Lens System*. But it is in just this direction

that the untiring work of Pagenstecher has accomplished so much. Where he has succeeded in establishing the diagnosis as to the nature of the cataract and its appendages to such a degree of accuracy that of 117 cases extracted with the capsule, the latter ruptured only four times, he has attained as high a degree of accuracy as one could desire. This much we must admit unhesitatingly."

With the operation of Major Smith (routine extraction of all cases in the capsule), the writer has no personal experience, and therefore will refer to it in only a few words. It should be said, however, that the visual result in Major Smith's cases is almost an unknown quantity, for in many instances the patients are discharged in a few days and lost sight of before any accurate visual tests are made. After doing ten of these operations, Cheney, of Boston, an exceptionally skillful operator and astute observer, concludes his report as follows: "While I am inclined to believe that a small per cent. of lenses may, with advantage to the patient, be extracted in the capsule, I shall do very little more pioneer work in attempting to determine the cases best adapted to this operation. There is one sentiment of Major Smith's, in his article in the *Archives of Ophthalmology*, that expresses so admirably my feeling on this subject that, although the application is a very different one, I will take the liberty of quoting it in concluding this paper: 'There is virtue in knowing when to quit and in letting 'well enough' alone.'

46 WEST FIFTY-THIRD STREET.

# REPORT OF A CASE OPERATED ON FOR ADVANCED ECTOPIC GESTATION ASSOCIATED WITH FIBROMYOMATA UTERI.\*

By STEPHEN E. TRACY, M. D.,  
Philadelphia,

Gynecologist to the Stetson Hospital.

Operation for the usual case of ectopic gestation offers no special difficulties for the experienced abdominal surgeon. When, however, the gestation develops beyond the third month and the sac becomes adherent to and receives a liberal blood supply from neighboring structures the operation is not only difficult but dangerous, and the patient may succumb before hæmorrhage can be controlled.

In operating on a case of advanced ectopic gestation the surgeon may carry out one of two procedures: 1. To open sac, remove the fœtus, suture the sac to the edge of the abdominal incision, and drain the cavity; or, 2, to make a complete enucleation. Should the surgeon doubt his ability to control the hæmorrhage an enucleation should not be undertaken. While the latter is the more complete surgical procedure, the former is no doubt the safer. In this case complete enucleation was carried out:

CASE. The history of the case is as follows: Mrs. W., aged thirty-seven years, nullipara; began to menstruate at the age of seventeen years. The menstrual periods occurred from twenty-nine to thirty-four days, lasted from five to seven days, and were always painful. On two occasions the intramenstrual period was six weeks, and at those times she supposed she was pregnant. During the last twelve years she had been confined to bed many times

with attacks of pelvic peritonitis. The last menstrual period prior to this illness was in September, 1907. The menstruation beginning on October 20th was scanty, and the period lasted about half the usual time. On the evening of December 20th, after being upon her feet a greater part of the day, she had discomfort in the pelvis and supposed she was about to develop another attack of peritonitis. She started to take a hot douche to relieve the discomfort, and almost immediately after the fluid began to run into the vagina she was seized with agonizing pain across the lower abdomen, became nauseated, and vomited. Two days later I saw the patient in consultation. At that time the pain was dull in character, and there was decided tenderness over the lower abdomen. Upon vaginal examination the pelvis was found filled with a hard conglomerate mass and nothing definite could be made out. Operation was recommended and refused. The following day the patient passed six or seven drops of blood from the vagina. The pain subsided gradually and the patient left her bed about three weeks after the beginning of the attack. From then on, although suffering with some discomfort in the left side of the pelvis, she was able to be up and about the house. In the early morning of March 1, 1908, she was seized with severe pain in the lower abdomen, after which she vomited and had diarrhoea. The following day the temperature was 101° F. and the pulse rate 120 per minute. After this attack of pain she consented to operation and was admitted to the Stetson Hospital the afternoon of March 3d.

Upon admission she had a temperature of 99° F. and a pulse rate of 80 per minute; the lower abdomen was tender, and there was a mass on the left side. Upon vaginal examination a mass was found which filled the pelvis and extended up the left side of the abdomen above the anterior superior spine of the ilium. The pelvic portion of the mass was hard, while the abdominal portion was soft. With the exception of a few drops of blood passed after the beginning of the attack in December, there had been no bleeding from the vagina; at times there was a slight, pinkish leucorrhœal discharge.

Operation was performed under ether anesthesia. When the abdomen was opened it was found that the gestation sac filled the left side of the pelvis and the lower portion of the abdomen, and was almost completely surrounded by adhesions. After placing gauze pads to protect the general peritoneal cavity, the hand was passed gently behind the sac to determine the anatomical relations. Scarcely had the sac been touched when the pelvic and lower abdominal cavities were flooded with blood. The sac was quickly enucleated and brought to the surface, and the portion attached to the left broad ligament clamped, cut, and removed. An attempt was made to temporarily control the bleeding by packing with gauze, but this was not successful until a large vessel, fully as large as any uterine artery I have ever seen, at the fundus of the bladder was ligated. By careful manipulation it was found that the uterus contained many fibroid tumors which were adherent in the bottom of the pelvis and could not be enucleated in the usual manner because the adhesions were very dense, and there was no room to work, as the pelvis was packed with gauze to control the bleeding. The bladder was then pushed down, the broad ligaments were clamped, the uterus was amputated at the internal os, and by making traction upwards on the uterus the fibroids were cut free by scissors and the bleeding points controlled by forceps from below upwards. After the uterus was removed, ligatures were applied and the forceps removed, and the toilet of the pelvis completed as after the ordinary hysterectomy. The bleeding from the omentum and along the edge of the bowel, which had been controlled by gauze pressure, was then controlled by ligatures. A few other bleeding points were then controlled, and the abdomen was closed without drainage.

Although this was a case of abdominal gestation, I believe it originated in the left Fallopian tube and was expelled through the side of the tube probably at the time the patient suffered with the first attack of pain, and that it continued to develop until the time of the operation. Whether the patient became pregnant after the normal menstrual period in September and the fœtus ceased to develop some days

\*Read before the Philadelphia Obstetrical Society, April 10, 1908.

before operation, or whether she became pregnant after the atypical menstruation in October it is impossible to say. It is probable that pregnancy followed the menstrual period in October and advanced until the time of operation. The time from the atypical menstrual period in October until the date of the operation was 137 days, or nearly twenty full weeks. One interesting feature about the specimen is that a portion of the placenta is entirely around the neck of the child.

The gestation sac in this case was attached to the distal end of the left Fallopian tube, the left broad ligament, the fundus of the uterus, and the bladder, the fibroid tumors adherent in the pelvis, the sigmoid and ileum and the great omentum. The of the bladder and from the ileum. An attempt was made to control the bleeding from the ileum by a continuous suture, but the hemorrhage was so profuse that it was necessary to clamp along the edge of the bowel for several inches and then to apply ligatures.

The patient, although badly shocked from the loss of blood, reacted promptly, and with the exception of a phlebitis in the left leg the convalescence was uneventful.

Such an experience teaches but one thing, and that is the value of early operation in all cases of ectopic gestation. The ideal time for operation is before rupture takes place. Unfortunately, the surgeon seldom sees these patients until after rupture has occurred. Had this patient submitted to operation when advised to do so by the family physician, the operation would have been a simple affair, and her life would not have been jeopardized.

#### THE BLADDER IN TABES.\*

By J. BENTLEY SQUIER, M. D.,  
New York.

The importance of a thorough appreciation of the rôle which motor or sensory irregularities of the urinary vesical function play in the diagnosis, course, and termination of posterior spinal sclerosis cannot be overestimated. A certain percentage of tabetic patients have their attention directed to disturbances in their urinary function as the primary discomfort. The percentage is not particularly great, but it is sufficiently large to emphasize the fact that the possibility of tabes should be kept in mind in diagnosing any case of unusual functional disturbance of the bladder.

If in eighty per cent. (Starr) of tabetic patients bladder symptoms are present, and in thirty per cent. (Erb) of these they form the initial symptoms, the value of this statement is manifest. Tabes, like the acute infection which is probably its only origin, has been divided, for ease of description, into the stages of paræsthesiæ, of ataxia, and of paralysis. This division, as in dividing syphilis into primary, secondary, and tertiary stages, is misleading, because any symptom or train of symptoms may be the initial one. Thus it is not an uncommon experience for the genitourinary surgeon to have a case of tabes brought to him for diagnosis or treatment where

from the symptoms only an organic bladder or prostatic lesion has been suspected. The distinctive diagnosis being often difficult, this error is easily explained, the difficulty being that even though the patient has tabes he may also have a real local lesion which is in part or wholly responsible for the bladder symptoms and not the cord degeneration. Vice versa, if the cord lesion is present and its presence is not recognized one may inadvertently propose some radical surgical measure for the relief of the urinary symptoms, presumably due to local causes, which are in reality due to a central lesion, thus leaving the patient in a more distressing condition than he would have been if no operation had been performed.

I have recently seen a patient whose prostate was removed for the relief of complete retention of urine, there simply being some enlargement of the prostate present. As the result of the operation the patient was left with complete incontinence, requiring the constant wearing of a urinal, and it was only after operation and the development of other signs of tabes that the spinal cord disease was recognized and the utility of operation recognized.

Two cases which I have already reported (see *New York Medical Journal*, March 16, 1907) were considered to be tabetic until multiple calculi were diagnosed and removed from the bladder with an immediate cessation of the bladder symptoms and lightning pains in the legs, which had been the salient points upon which the diagnosis had been made.

To go further, tabes is not in itself fatal. It renders the patient a chronic invalid, but does not kill. He dies from some intercurrent disease, the most common of which, from the surgical standpoint, are complicating cystitis or pyelonephritis. To guard against these sequelæ makes the knowledge of how to deal with any urinary difficulties occurring in the course of tabes imperative.

Bladder symptoms when present usually present themselves as (a) varying degrees of retention of urine, or (b) varying degrees of incontinence of urine, in accordance with the degree of interference in reception of sensation to the mucous membrane or of the muscle of the bladder. For example, the vesical symptoms may be so slight as to escape the patient's notice, or the patient may have hesitancy in commencing micturition. When the desire to urinate occurs he may be unable to control it, and a few drops may escape before he can reach the toilet. In laughing, coughing, or in sleep there may be slight incontinence, or he may have absolute incontinence, or absolute retention. Any of these symptoms may be wholly due to the central lesion. On the other hand, if infection of the urinary tract takes place from septic instrumentation or autoinoculation, all the other symptoms of cystitis, prostatitis, vesical calculi, and pyelitis may be added. By autoinoculation is meant that condition ever present in tabes of trophic disturbances which renders the patient peculiarly susceptible to infection of the bladder or kidneys. A colon bacillus infection taking place through the lymphatics or from a direct extension through the rectal walls may be the cause of a fatal termination of the disease. This lack of resistance to bacterial invasion is forcibly shown in the fre-

\*Read before the Medical Association of Greater New York.

quency with which perforating ulcer of the foot follows a corn, a bunion, or a boil.

To illustrate I have selected a few cases of tabes which are at present under observation, each of which teaches an important lesson, and each shows different aspects of the manner in which the bladder involvement may present itself.

CASE I.—The first patient, a male, thirty-five years of age, developed his primary symptoms of tabes in August, 1907. The initial symptoms presented themselves in an attack of gastric crisis. After this, with considerable rapidity, stiffness of gait, dizziness when walking, lightning pains in legs, and other classical signs, subjective and objective, developed. He had acquired syphilis when twenty-five years of age. No bladder disturbances developed until a few days ago, when complete retention suddenly took place. At no time during the past eight months in which he had been under observation had there been any bladder disturbance.

CASE II.—The second case, a male, sixty-one years of age, consulted me September last, suffering from complete retention of urine of eight years' duration, requiring the constant use of the catheter. He had been a sufferer from tabes for fifteen years. The bladder symptoms in his case had been slow in their manifestation, commencing with increased difficulty in urination. This became gradually worse until complete inability to void urine took place. During this period of eight years he had had probably a dozen attacks of violent cystitis due to infection from his catheter. He had never been properly instructed in the care of the instrument.

CASE III.—Another patient who has been under observation for the past five years, whose tabes have been present for fifteen years, when first seen was suffering from symptoms due to a large vesical calculus in addition to bladder changes produced by his tabes. Removal of the calculus cleared up most of his bladder symptoms except a little hesitancy and at times a few ounces of residual urine. It has been this patient's custom for the past four or five years to take a number of courses of antisyphilitic treatment two or three times a year. During these periods of treatment he takes large doses of potassium iodide, and at these times his bladder symptoms are always aggravated. The congestion of the mucous membrane of the bladder and urethra caused by the iodide adds just enough extra obstruction so as to interfere with the act of urination, therefore during these courses of treatment he has to make use of the catheter frequently to relieve the hesitancy thus produced.

CASE IV.—The next case shows the symptom of incontinence as the most prominent urinary factor. The patient was attacked with tabes when thirty-six years of age, sixteen years after he had acquired syphilis. The initial symptoms were frequency of urination and ataxic gait. He was compelled to urinate ten to six times at night with more or less incontinence. During the day it was necessary for him to wear a nappy continually. The bladder always contained eight to ten ounces of residual urine.

These cases show the usual ways the bladder symptoms appear. Now the most important question arises, "What can be done for the relief of these distressing conditions?" Tabes is a disease the treatment of which is one of absolute attention to detail, and it is therefore necessary, if one expects any improvement whatsoever, to seek out every factor which may contribute any peripheral irritation to the already degenerated centres. I mean by this that it is not sufficient to simply teach the patient the use of the catheter to relieve the symptoms of retention or the incontinence of overdistention or intercalary incontinence, but it is necessary to go into the care of his urinary apparatus minutely. In examining the patient with tabes in which urinary symptoms are present, one should be absolutely certain that no local lesion of the urinary tract is overlooked. The congenital abnormally tight meatus if

present, should be divided, the possibility of stricture due to gonorrhoea should be considered, chronic congestion of the deep urethra or prostate, or any possible source of peripheral irritation should be inquired into and treated. This is necessary before one can tell how much of the patient's discomfort is due to tabes and how much to contributory irritation from outside sources.

Having eliminated all other pathological conditions which might be present in a tabetic bladder or annexa, the question of treatment resolves itself into a twofold proposition: First, and most vital, to keep the viscus in an absolutely sterile condition; second, to reestablish, by motor reeducation, its lost function. The first proposition is a surgical probability, the second an experimental possibility. In the motor training in ataxia we are often astonished by the amount of improvement which has taken place in many patients when we consider the amount of disturbance of the posterior sensory tracts which must be present. The reason need not concern us. Tabes is at present a necessarily symptomatically treated disease, and we have to be governed accordingly. Therefore, to take up the second possibility of treatment, as soon as the patient shows any hesitancy or incontinence the bladder instruction should begin, the technique of which is simple. After urination a catheter should be passed, the residual urine, if present, drawn, and a measured quantity of a mildly irritating fluid (silver nitrate, 1 in 1,000) injected into the bladder, and the patient required then to make efforts to void it. He should be taught the value of making his efforts of urination at stated times, and always to try to evacuate the bladder to the last drop. Sometimes a stronger solution of silver (grain I or II to the ounce) may be instilled into the prostatic urethra with beneficial results. It will excite a condition of mild vesical tenesmus, thereby stimulating the contractile power of the bladder. The vesical spasm of tabes is best relieved by the passage of a cold sound. If it becomes necessary to put the patient on catheter life no detail in his instruction in sterile catheterization should be overlooked, as upon this may depend the extent of his lease of life.

20 EAST FORTY-SIXTH STREET.

Neue Wege (Modern Ways). Baumbach, the well known German author, has written a drama in three acts, which is published by Friedrich Gutsch, of Karlsruhe. In the play the son, a young graduate of medicine, returns from the university to the home of his father, a well known physician, where he meets his early sweetheart. The young girl falls suddenly ill, and the elder physician, deciding to try a new remedy of his own discovery which he has not yet tested clinically, administers it to her, and she dies. At her death he is made aware for the first time that she was engaged to his son. The son is penetrated with grief over the death of his fiancée, and decides to leave his father's house and in bidding farewell to his father says: "Would you have treated Maria as you did, if you had known she was my affianced wife, your future daughter?"

## Our Readers' Discussions.

### A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at frequent intervals. So far as they have been decided upon, the further questions are as follows:

LXXIV. How do you treat sunstroke? (Closed May 15, 1908.)

LXXV. How do you treat cholera infantum? (Answers due not later than June 15, 1908.)

LXXVI. How do you treat acute articular rheumatism? (Answers due not later than July 15, 1908.)

Whoever answers one of these questions in the manner most satisfactory to the editors and their advisors will receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but not required) that the answers be short; if practicable, no one answer to contain more than six hundred words.

All persons will be entitled to compete for the prize, whether subscribers or not. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish. All papers contributed become the property of the JOURNAL.

The prize of \$25 for the best essay submitted in answer to question LXXIII has been awarded to Passed Assistant Surgeon Charles S. Butler, United States Navy, whose article appears below.

### PRIZE QUESTION NO. LXXIII.

#### HOW DO YOU TREAT SEASICKNESS?

By CHARLES S. BUTLER, M. D.,  
United States Navy.

It may be stated at the start that there is no specific for seasickness. The psychic attitude toward a given drug influences so markedly its effect upon the patient in this particular complaint that we find the apparent paradox of a single drug seeming to intensify in one person those symptoms which it relieves in another. Thus it happens that almost every known drug has been tried and recommended in seasickness. Promiscuous drugging in seasickness is pernicious rather than beneficial.

I think that the effort of the physician should be to lead his patient up to the acquirement of an immunity—to use this term in its broad sense—rather than to be content with simply mitigating existing symptoms. No immunity begotten purely of drugs can long endure; it passes with the drug.

Immunity to seasickness is only relative. Under unusual stress of weather the hardiest sailor may fall victim to the complaint. But it should be the earnest desire of every one who goes to sea to acquire such a degree of immunity as will furnish a reasonable return in comfort during the ordinary conditions on the ocean.

Bromides, alcohol, or opium can never give this "something," which, like the knack of swimming, once acquired, lasts for life. What these drugs give is a temporary and imperfect imitation of the real thing. People who are not used to going to sea are wont to forget, amid the unusual surroundings aboard ship, the daily routine which, on shore, gives them the best returns in wellbeing. They lose sight of the fact that to sleep in a stuffy stateroom, to neglect the daily exercise or cold dip, will have exactly the same effect upon them as if they were on

shore. To offset seasickness they need all that well-being and hold on the will which a well regulated routine will give them. It would seem that the quickest way out of seasickness is not by the drug route, but by the immunity route, and to this end I may divide travelers into three classes:

1. Those who naturally have a comparative immunity to the complaint, suffering with slight nausea in the beginning of a sea voyage, which quickly passes off. This class requires no treatment.

2. Those showing more persistent symptoms, psychic (depression of spirits) and cerebral (headache and vertigo), as well as gastrointestinal (anorexia, nausea, vomiting, and constipation), but who, with proper care, ultimately acquire an immunity.

3. Those who can never become used to the oscillation of a ship, however long or often subjected to it.

It is the exception to find an individual who properly belongs in this last class, by far the majority of people falling into one of the first two classes.

It is only to this last class that the usual sedative treatment with bromides, or chloral, or atropine, should be applied, and then only after we are assured that the individual is one of those rare unfortunates. The only thing to do for him is to make him as comfortable as possible, and support his strength until the voyage is completed. How to do this is a matter to decide for each individual case, but generally speaking, a reclining or recumbent position (on deck, whenever possible), an easily digested diet taken at frequent intervals, as much reading as is consistent with pleasure, and the avoidance of sleep until night, will give the best results.

To these general measures special measures as required may be added. The sipping of a sparkling laxative water, well iced, is often beneficial, and, as a general rule, the application of a snug abdominal binder, from chest to hips, will prove of service. In women this, of course, should displace the corset, which does not give proper distribution of the pressure.

To return to the second class, which embraces the great majority: The pathology of seasickness has never been written. To this assertion the multiplicity of hypotheses to explain it attest. Not knowing its cause our treatment then becomes empirical, and hence not ideal. Disregarding personal handicaps, such, for instance, as an already existing gastritis, a naturally torpid liver or other complaint which may predispose one to seasickness, those individuals fare best whose secretions are most active, who early acquire the knack of orientation, and whose dispositions are most optimistic. To aid and encourage these three things in the patient offers the best chance for early acquiring the immunity of which I speak. To this end it is well to have the person, before sailing, if time permits, take a thorough course of catharsis. If the individual knows when he is to sail, it is well to have him take a cholagogue cathartic about a week beforehand, and then keep the bowels in an open condition with some saline cathartic. During this time the diet should be light and largely composed of vegetables. The meal immediately before sailing should be a full one. It is best to leave alcohol entirely alone.

Nothing will so surely precipitate seasickness as a little too much alcohol the night before. So, too, with coffee, tea, and tobacco. The two first named not only tend to constipate, but also disturb the rest and so produce a certain ennui, the very reverse of what should exist at the sailing time. With a good start the battle is half won. During the voyage it is well to avoid coffee, tea, and tobacco until one is assured he can take them without undue detriment. When indulged in they should be taken in the early part of the day, not toward evening. Plenty of sleep and an active condition of the bowels should be the rule throughout the voyage. Sleep during the day should be discouraged. It is calculated to make the regular sleeping hours less refreshing. To promote laxity of the bowels, three measures may be employed in case the individual is inclined to be constive, and such is usually the case with those who are seasick. At night, after turning in, and when drowsiness has come on, administer one of the stomachic and laxative pills containing aolin, strychnine, belladonna, and ipecac, a combination which most manufacturing pharmacists prepare. This usually acts well the following morning, and if administered as directed, is rarely vomited. Or before turning out in the morning have the patient take a glass of a purgative mineral water, and remain quiet for a time. In case these preferred measures should fail, then recourse should be had to enemata. Every traveler should be provided with one of the little soft rubber bulb syringes with a capacity of four to six ounces. By injecting cold water (five ounces) when one arises—a procedure requiring but half a minute—the desired effect will usually be attained by the time the patient is ready to go for his bath.

The next question after guarding the welfare of the gastrointestinal tract is that of orientation. When the novice starts on a voyage, his first pleasurable sensations at the slighter motions of the vessel soon give place to that disagreeable feeling which one experiences in a rapidly descending elevator. Of the several motions of a ship, the one on the thwart-ship's axis (the pitch) is by far the most effective in producing this sensation. This is attributed to the fact that we anticipate the roll, but not the pitch. It seems to me that there is something other than anticipation needed to explain this, for the seasoned sailor can no more anticipate it than the novice, and yet he is not affected by it. He has taught his equilibratory apparatus to disregard it. He goes with the ship and does not resist going where she goes. He is, in a certain sense, passive, whereas the novice keeps his equilibratory apparatus in a constant state of insult by trying to draw back, much as one imagines a man would who was being shoved over a precipice. It is this constant tendency to try and right the ship rather than to be a part of her which must be overcome, and I think when one has accomplished this he has gone far towards becoming a good sailor. To accomplish this is largely a matter of inhibition, and is accomplished by the will. Practice may be acquired in this inhibition by using vigorously one of the old time swings known to us as children. It may be aided by deep inspiration at the time of descent, repeated

regularly until this kind of respiration becomes a habit.

The third element making for immunity, the cheerfulness, is rather contributory than essential. It is difficult to further a determination to resist to the last when one feels that awful goneness at the pit of the stomach, but it is certain that the capacity for optimism aids the will at the time when it most needs it.

*Conclusion:* We may summarize the treatment of seasickness thus: 1. Avoid sources of depression, such as tea, coffee, alcohol, and tobacco.

2. Keep the secretions active.

3. Learn to be a part of the ship.

4. Cultivate a good daily routine as to meals, baths, exercise, etc.

5. Stay on deck and amidships as much as possible.

6. Never take sedatives until compelled to.

7. Cultivate cheerfulness.

*Dr. B. R. O'Reilly, of Toronto, Canada, remarks:*

There is no disease which will tax the "ship surgeon's" resources to such an extent as a severe case of *mal de mer*, for not only has he to deal with the physical manifestations, but added to these are those mental symptoms of apprehension, etc., from which frequently the patient suffers far more than from the nausea and vomiting itself.

Seasickness declares itself in several distinct ways. In my experience none can compare, from the patient's standpoint, with that nervous type showing itself in intense occipital headache, severe spinal neuralgic pains, mental trepidation, etc. (frequently unaccompanied by vomiting), and, although a certain amount of relief may be afforded, these patients can seldom be given any permanent degree of comfort. One can divide cases of *mal de mer* into two classes, for the purpose of laying down certain general rules as to their management, i. e., the "gastric" and "nervous." In the former group we meet with every degree of suffering from simple vomiting unaccompanied by nausea to uncontrollable emesis, with the serious problem, during a long voyage, of the maintenance of nutrition before us.

Prophylaxis may be of great service, especially in this form, and it is here that on the second night before embarking a full dose of calomel, followed the next morning by a saline draught, or large warm water enema, has its place; minor points, such as a cup of hot tea or coffee before rising, abstinence from the time honored tramp before breakfast, a somewhat hasty plain meal, and immediate recourse to a lounge chair on deck, should never be forgotten. Some individuals experience excellent results from a dose of effervescent saline on waking, or a full tumbler of sea water, in the latter case the induced emesis apparently acting as a gastric sedative, and this is the favorite method adopted by Chinese sailors in the Orient.

Occasionally a firm abdominal pad or binder, or a belladonna plaster over the epigastrium, will add not only to the patient's comfort, but in certain individuals may even ward off an expected attack.

The patient should be warmly and comfortably clad, nothing add more to the misery than ensa-

tions of cold. Encourage the sufferers to take a moderate amount of nourishment, the stomach being less impressionable during the process of digestion.

For the relief of nausea uncontrolled by simple remedies such as have been suggested, one must have recourse to more active measures, and foremost among these comes the application of sinapisms to the epigastrium; gastric lavage is often eminently successful, and this opportunity may be used for the introduction of such drugs as bismuth, carbonate, creosote, hydrocyanic acid, or cocaine (in doses of 1/8 grain), into the stomach; drachm doses of glycerin have also been recommended. These having failed, we have still several means at our disposal for relieving the depression, even if we cannot control the active emesis, and it is in these cases that the use of the hypodermatic syringe finds its place. In individuals who know by experience that severe nausea and vomiting are inevitable, a prophylactic injection of 1/100 grain of atropine sulphate combined with 1/50 grain of strychnine sulphate will do much to inhibit its onset. The drug on which I place greatest faith is nitroglycerin, in doses of 1/100 grain, the subjective symptoms of depression frequently being ameliorated, even though vomiting persists.

The use of champagne and the sucking of ice may be allowed, although it is doubtful if much value can be attached to their action, beyond the mental impression they produce, and in the same category I place the use of brown paper over the abdomen and many other similar expedients. Lastly, it may be necessary to relieve thirst with saline injections and employ nutrient enema to support nutrition.

Turning now to the nervous type of the malady, one's advice and procedure as to prophylaxis is similar, but following this a different course of treatment is usually found to be advantageous. Theoretically, the nausea and vomiting being ascribed to a central reflex disturbance (possibly due to an alteration in the normal conditions of the endolymph and perilymph of the semicircular canals), the ætiological factor being the same, one's treatment of the two forms should be similar.

Experience teaches us that it is here the sedatives are of greatest value, and probably none are more useful than the bromides (given in doses of 20 grains every six hours for at least two days before embarking, preferably the strontium salt), or chlorotone in 5 grain gelatin capsules or paraffin wafers, and repeated every four to six hours (it is officially known as trichlorotertiary butyl alcohol, is a crystalline salt, nearly insoluble in water, volatilizes at low temperatures, and should therefore be kept in glass stoppered bottles).

One may, especially in cases of headache and spinal pains, get marked relief from the "coal tar" products, and of these phenalgin (which contains ammonia) is the safest and least depressant, and in my experience is the most reliable. Hyoscine has been used extensively, but cases have been reported in which mania lasting for several days has been the outcome; lastly, and never to be used except in the most extreme forms, comes morphine.

In concluding let me emphasize the fact that, while seasickness is seldom in itself a menace to the life of the patient, it may, and not infrequently does,

precipitate serious complications, such as cerebral hæmorrhage or the rupture of a previously existing gastric ulcer, and that the treatment of even the apparently mild cases should receive more than a passing thought; finally, the future holds out to us the hope that in the "gyroscope" we may find an antidote which will displace entirely our present system of therapeutics, and that ultimately *mal de mer* will be a disease of the past.

Dr. Robert A. Bachmann, of the United States Navy, writes:

If possible the treatment of seasickness should be begun before the attack. A subject of the disease prior to embarking on a voyage should be prepared by dietary regulations and a thorough catharsis two days before. The former means simply a restriction in diet as to quantity, particularly in the reduction of meats and fats, eliminating everything but possibly a small amount of light meat once a day, and the latter is best accomplished by fractional doses of calomel (0.1 grain for ten doses as an average dosage), followed by a Seidlitz powder or magnesium citrate in the morning. Whether the *modus operandi* of the calomel is to increase peristalsis or stimulate the liver, the object—to get rid of as much bile as possible in the intestines—is accomplished.

The day before sailing, small doses of potassium bromide are useful in quieting the vomiting centre as well as the sensibility of the semicircular canals and lessening the irritability of the stomach. Ten grains three times a day are sufficient for this purpose.

The treatment on the ship demands two most important conditions—fresh air and the reclining position. Frequently these accomplish a cure without medication or diet. Senseless advice to "fight it off," not to "give up," but to spite your stomach and eat in the face of nausea or walk around when the semicircular canals should be at repose, is not only bereft of good reasoning, but positively plagues your patient.

With the beginning of rough weather inject atropine sulphate 0.01 grain, and hyoscine sulphate 0.005 grain, every three hours until two or three doses produce dryness of mouth, cessation of nausea, and a desire to sleep.

The patient is placed on deck amidships, where motion is least, in a steamer chair or cot, head on a soft pillow, and well blanketed. The absence of odors, especially of tobacco smoke, is greatly appreciated by your patient. If symptoms of seasickness develop in spite of the treatment, or in late cases, if they do not abate, I add a twenty grain dose of potassium bromide in fruit juice and aerated water, and follow it with ten grain doses every three hours. Women are often benefited by warm applications to the epigastrium and abdomen, and severe cases of retching and vomiting in either sex are improved by this as well as hot applications to the head.

The most delectable nourishments are fruits and fruit juices, light broths, crisp crackers, toast well baked, zwieback, and later the lighter meats, eggs, egg desserts, etc. Champagne, cracked ice, and aerated waters are the best drinks. The sucking of an orange or lemon is pleasant to some. Personal tastes must be considered.

After the patient has improved do not risk a relapse by letting him be too active. Keep him in the open air, reclining, and further his recovery by giving strychnine 1/20 grain three times daily, or five drop doses of tincture of nux vomica in water every three hours. The natural tendency most people have to become constipated at sea is best corrected by a morning dose of fluidextract of cascara sagrada.

The three main considerations to obtain are a normal digestive tract, fresh air, and the reclining position. With these to work on such medication as has been mentioned will hardly fail to give at least relief.

*Dr. Irving Wilson Voorhees, of New York, says:*

At the outset it should be thoroughly understood that this condition is dependent upon no single cause, but upon a variety of causes operating locally to influence the abdominal organs and constitutionally to disturb the equilibrium of the central nervous system. Without going into the alleged causes of *mal de mer* in detail there are two theories which are supported by an overwhelming amount of clinical evidence. The first of these argues that the abdominal organs are pulled in various directions by the swaying of the ship and thus set up a reflex irritation of the sympathetic ganglionic system, with its attendant results; the other avers that there is a disturbance of the pneumogastric nerve, either mechanical, thermal, psychic, or toxic, and that this is responsible for the distressing symptoms. That there is some (but not all) truth in each of these hypotheses is beyond question, but they do not cover the actual conditions in every case, as our therapeutic efforts prove.

Stomach washing and catharsis have proved to be of value in my experience. As soon as nausea begins the stomach is washed with water at 90° F. containing 10 minims of nux vomica, which is continued until the water comes away absolutely clear. Unless the bowels are already very active, physostigmine sulphate, grain 0.01, is given hypodermatically. I prefer this to the use of the internal cathartics, because it acts quickly and does not irritate the mucous coat of the gastrointestinal tract.

Ergot by mouth is useful in a limited number of cases, particularly those of a neurotic type, with congestion of the gastric mucosa. I give to adults 1/4 drachm in a little water every four hours.

The bromides have been in use for years, and are highly recommended by some writers. Personally they have given me poor satisfaction.

Hyoscine, atropine, strychnine. A combination of hyoscine hydrobromide, grain 1/100, atropine sulphate, grain 1/100; and strychnine sulphate, grain 1/60, by hypodermatic injections, not oftener than every four hours, is sometimes useful.

Morphine, atropine, caffeine citrate. This is the best method of controlling obstinate sickness, with which I am familiar. As soon as nausea begins the patient is given an 1/4 grain of morphine with a 1/100 of atropine in 15 drops of sterile water by hypo. If nausea is still present one hour later, give caffeine citrate, grain iv, in 25 drops of sterile water by hypodermatic injection. The atropine should not be repeated within four hours. Occa-

sionally atropine must be given on the following day if the sea is very rough.

*Essentials.*—The patient should make sure before sailing, in so far as possible, that his *nervous and gastrointestinal systems are in prime condition*. This is, of course, impossible with many patients who must sail at once, but the use of phosphoglycerates of lime and soda or the syrup of hypophosphites with strychnine is very helpful when given for one month before sailing.

The patient should be kept in the open air, preferably on deck, lying flat on his back in a swinging hammock. When the port holes are all closed and the patient is tossed about in his berth in a foul atmosphere and surrounded by the noises and odors of other sick people he is not in the best possible environment for an immediate recovery.

A broad belt, extending from nipples to pubes, tightly applied gives much relief. I have seen it help when all other measures accomplished very little.

It is best to abstain from all food and drink. Even water will sometimes start a new attack of vomiting, and if given at all it should be by teaspoon. If the patient is in immediate danger of starvation, one has recourse to rectal enemata.

*Dr. Frederic H. Wilson, of New York, observes:*

In dealing with the affection known as seasickness or *mal de mer*, it is necessary to take into consideration two things, namely, whether the sea trip is to be of long duration, as a transatlantic voyage, or merely a day's outing on a pleasure craft. In either case, prophylaxis is a most important factor in the treatment, but is seldom possible in the latter case. Most patients who anticipate a lengthy voyage are deluged by well meaning friends with various suggestions for eliminating the bugaboo of the trip, varying from sucking a lemon to an almost constant sojourn on deck. The writer uses two courses of treatment, both of which are successful in the majority of cases and which have stood the final test of any treatment by a physician, namely, using them on himself.

The patient who is going on a pleasure excursion, as a short yachting trip, and who comes to me for advice as to how to avoid being seasick, is given, on the evening before sailing, a hypodermatic injection of strychnine hydrochlorate, grain 1/60, and atropine sulphate, grain 1/150. The majority of those who ask for advice are ladies, who are somewhat dubious when the hypodermatic is suggested, and I therefore am frequently obliged to medicate by mouth. On the morning of the journey another dose is given, this time by mouth in all cases, using the strychnine in a dose of grain 1/30, and the atropine, grain 1/100. The patient is advised to refrain from rich food and copious drinking during the day, and freedom from the dreaded nausea is the result in almost all cases.

On the other hand, the treatment for a protracted long voyage is necessarily much more thorough and should cover a longer period of time. The patient is told to take every morning, for five days previous to embarking, a small dose of strychnine. On the afternoon of the day before sailing the patient is given a dose

mel, grain  $1\frac{1}{5}$ , for five doses, followed by another Seidlitz powder on the morning of departure. By this prophylaxis the entire intestinal tract is cleared and the liver put into good functioning condition. The absorption of toxic material from the lower bowel becomes greatly increased by the rolling of a vessel, and the described treatment eliminates a large part of the toxins arising from intestinal putrefaction.

The patient should occupy an "outside" stateroom and keep the window or porthole open as much as possible, especially at night. He should be particularly cautioned to spend as little time as possible in his stateroom or in the cabins. During the first days of the voyage only light meals should be eaten, whether seasick or not, as the appetite, stimulated by the sea air, will invariably cause a voyager to overtax his digestive organs unless strict care is maintained.

A very valuable point is the following: After the first few days the patient will find no inclination to seasickness except on arising. When this occurs he should dress as expeditiously as possible and immediately go on deck instead of to the dining saloon. While in the chair on deck he should have the deck steward serve to him an iced grapefruit, slightly sugared, which should be eaten, together with several pieces of the ice served with it. The lumps of ice should be swallowed whole. The bracing effect of the bitter (cinchona) of the grape fruit is immediately noticeable, and within a few minutes a hearty breakfast can be eaten in the saloon. I have known this routine of treatment to enable the most acute sufferer from *mal de mer* to pass through a nine day voyage, including a two day storm, with no more serious inconvenience than a slight nausea and giddiness on arising in the morning and lasting less than a half hour daily.

(To be concluded.)

## Correspondence.

### LETTER FROM OTTAWA.

*The Forty-first Annual Meeting of the Canadian Medical Association.—The Eighth Annual Meeting of the Canadian Medical Protective Association.—The Second Annual Meeting of the Association of Medical Officers of the Militia of Canada.*

OTTAWA, May 16, 1908.

The forty-first annual meeting of the Canadian Medical Association will be held in the Capitol, Ottawa, on the 9th, 10th, and 11th of June, under the presidency of Dr. F. Montizambert, of Ottawa, director general of public health. Dr. R. W. Powell, of Ottawa, is the chairman of the Committee of Arrangements. Delegates to this meeting will travel from every province in Canada on the standard certificate plan. During the course of the meeting, as usual, the annual meeting of the Canadian Medical Protective Association will take place, when the president of that lusty organization, Dr. R. W. Powell, of Ottawa, will have a splendid report to make. This organization came into existence at the Winnipeg meeting of the Canadian Medical Association in 1901. Every year it has prospered both in numbers and in finance. During that time it has defended a number of its members in suits for alleged malpractice,

and in no instance where it undertook a defense has it been other than successful. Indeed, its power and strength are becoming known to the extent that year by year there are fewer actions of this character all over Canada. The Military Surgeons this year, under the presidency of Dr. George Stirling Ryerson, of Toronto, meet as a section of the Canadian Medical Association. The social side of these meetings promises this year to be more than ordinarily interesting. There are to be a reception at the Ottawa Golf Club, an excursion to Caledonia Springs, an excursion to the Experimental Farm, and a smoking concert, besides numerous private functions. This is the first meeting under the new constitution, and the provincial societies are sending delegates to represent them on the business body of the association, the Executive Council.

The Presidential Address will be given by Dr. F. Montizambert, of Ottawa; the Address in Medicine by Dr. Risien Russell, of London, England; and the Address in Surgery, The Surgical Rights of the Public, by Dr. John C. Munro, of Boston, Mass.

## Therapeutical Notes.

**A Bath for Urticaria.**—In *La Clinique* for May 15th G. Bardet is credited with the following formula for a powder to be added to the bath water in the treatment of urticaria:

B	Potassium carbonate, .....	3iij.
	Sodium carbonate, .....	5ii.
	Sodium borate, .....	3i.
	Pulverized starch, .....	3iiss to 3vij.

M.

After the bath it is recommended to rub the skin lightly with glycerite of starch containing one per cent. of carbolic acid.

**Enema in Intestinal Tuberculosis.**—Soubeyran and Ardin Delteil (*Journal de médecine de Paris*, April 24th) use the following as an enema in the treatment of tuberculosis of the intestines:

B	Methylene blue, .....	gr. i to gr. ii.
	Distilled water, .....	3xvi to 3xxxii.

M.

Or,

B	Naphthol camphor, .....	3ss.
	Yolk of egg, .....	No. i.
	Distilled water, with milk .....	3x.
	Wine of opium, .....	gtt. vi.

M.

[Naphthol camphor consists of a mixture of beta-naphthol, 100 parts, and camphor, 150 parts.]

**Solution of Formaldehyde for the Destruction of Flies and Mosquitoes.**—In the *Archives de médecine et de pharmacie militaires* for April, 1908, M. Delamare, chief of the military wards of the hospital of Saint-Denis, describes a method of destroying flies and mosquitoes in apartments by the use of a ten per cent. solution of commercial formaldehyde. Saucers containing the solution are placed on the window sills and on tables in proximity to the places infested by the flies. The solution is said to be very effective, flies and mosquitoes being arrested and killed in their flight as they pass over the vessels containing it. Saucerfulls of the solu-

tion, placed at the heads of the beds in the hospital wards, protect the patients from attacks. The author had the curiosity to count the number of insects killed, and found that, during the period from August 1 to August 7 the daily average was 4,000 flies. The saucers should be emptied of dead flies and replenished with fresh solution once a day.

**Application for Toothache.**—After the cavity has been thoroughly cleansed and dried, J. O. Hart (*The Virginia Medical Semi-Monthly*, May 22d, 1908) applies the following on a pledget of cotton:

R Chloroform,  
Oil of cloves,  
Creosote, ..... 3i. 5ss.  
Morphine sulphate, ..... ʒi. gr. i.

M.

To reduce periosteal inflammation, the surrounding gums should be painted with equal parts of tincture of iodine and tincture of aconite.

**Injection for Fœtid Bronchitis.**—Rabé (*Journal de médecine de Paris*, April 24th) injects hypodermatically two to four cubic centimetres of the following preparation during the twenty-four hours:

R Guaiacol, ..... gr. lxxv;  
Iodoform, ..... ʒi. gr. xv;  
Sterilized oil, ..... ʒi. gr. i.  
Liquid petrolatum, ..... āā q. s. ad ʒiii.

M.

**Styptic Powder.**—The composition of a styptic powder used by Professor P. G. Unna is as follows:

R Tannic acid,  
Alum, } ..... āā gr. xv.  
Acacia, }  
Rosin, }

The ingredients, finely pulverized, are intimately mixed together.

**Metchnikoff's Mercurial Inunction.**—The ointment employed by Metchnikoff at the Institut Pasteur for the prevention of inoculation by syphilis is composed as follows:

R Calomel, ..... ʒi. gr. i.  
Petrolatum, ..... 10 parts;  
Anhydrous wool fat, ..... 67 parts.

M.

It is important in preparing this ointment to avoid the slightest contamination with water, and care should be taken to insure the use of perfectly anhydrous petrolatum and wool fat.

**Tonic and Reconstructive Cachet.**—The following combination, credited to Milian in *Journal de médecine de Paris*, is said to be useful in weakened conditions marked by alopecia:

R Sodium chloride, ..... gr. xxi.  
Quinine sulphate, ..... gr. iss;  
Calcium glycerophosphate, ..... ʒi. gr. i.

M. ft. cachet i.

Sig.: One cachet twice daily at meal time.

**Gout Treated with Hydrochloric Acid.**—Falkenstein, of Berlin, having observed that the majority of gouty patients suffered from hydrochlorhydria arrived at the conclusion that the gout was the result of trouble with the gastric mucus characterized by an insufficiency of hydrochloric acid, this poverty of the organism in hydrochloric acid preventing the formation of alkali chlorides, and, as a consequence, their elimination by the kidneys. When hydrochloric acid is lacking in the system the alkali enter into combination with the uric acid, and as

urates do not pass through the kidneys, they remain in the blood, where they cause all the troubles with which we are familiar. The internal administration of hydrochloric acid in doses of fifty drops a day favors the elimination of alkalies by the kidneys and so prevents the formation of deposits of urates in the joints. The treatment is said to be well tolerated, and there is reason to hope that recent cases of gout are curable by this method of treatment.

**Hiccough in Children.**—Teaspoonful doses of the following are given at intervals until the hiccough stops:

R Syrup of poppy, ..... 5v;  
Chloroform, ..... ʒi. gr. xx;  
Syrup of peppermint, ..... ʒi. gr. i;  
Oil of sweet almond, ..... ʒi. gr. i.

M.

*Bulletin général de thérapeutique*, April 8, 1908.

**Inhalation for Bronchitis in Children.**—The inhalation three or four times a day of the vapor from a teaspoonful of the following mixture added to a quart of water heated in a teapot or kettle is recommended for the treatment of bronchitis in children:

R Wood creosote, ..... ʒi. gr. i;  
Tincture of benzoin, ..... ʒi. gr. i;  
Oil of turpentine, ..... ʒi. gr. i.

M.

**Intravenous Injections in Infectious Diseases.**—Bacelli, of Rome (*Journal de médecine de Paris*, April 24th), has effected cures in malarial subjects by the intravenous injection of quinine hydrochloride dissolved in physiological salt solution, of the following strength:

R Quinine hydrochloride, ..... gr. x;  
Physiological salt solution, ..... ʒi. gr. xv.

M.

The injection is made preferably with a glass syringe, the part of the body selected being first made aseptic, and if the bend of the arm is chosen as the site of the injection, an elastic band is first applied. It is of the utmost importance to avoid the introduction of bubbles of air in making the injection. Twenty-four hours after fifteen grains of quinine are administered in this way the blood is found to be free from the malarial parasites.

In the treatment of syphilis he uses the following formula:

R Corrosive sublimate, ..... gr. xv;  
Sodium chloride, ..... ʒi. gr. i;  
Distilled water, ..... ʒi. gr. i.

M.

He begins by injecting fifteen minims of this solution, and increases the dose until he reaches a maximum of ten times this quantity as the daily dose. The injections are considered equally serviceable in the treatment of puerperal infection, cerebrospinal meningitis, acute articular rheumatism, and erysipelas.

**Ointment for Psoriasis.**—The following ointment, credited to Safford in *Journal de médecine de Paris*, is applied once a day, bathing being immediately during the treatment:

R Salicylic acid,  
Chrysarobin, ..... ʒi. gr. i;  
Green soap, ..... ʒi. gr. i;  
Petrolatum, ..... ʒi. gr. i.

M.

## NEW YORK MEDICAL JOURNAL

INCORPORATING THE

Philadelphia Medical Journal  
and The Medical News.*A Weekly Review of Medicine.*

Edited by

FRANK P. FOSTER, M. D.,  
and SMITH ELY JELLIFFE, M. D.

Under Domestic Postage Rates, \$5; under Foreign Postage Rate,  
\$7; single copies, fifteen cents.Remittances should be made by New York Exchange or post  
office or express money order payable to the A. R. Elliott Pub-  
lishing Co., or by registered mail, as the publishers are not  
responsible for money sent by unregistered mail.Entered at the Post Office at New York and admitted for  
transportation through the mail as second class matter.

NEW YORK, SATURDAY, MAY 30, 1908.

## THE CHAILLE JUBILEE.

"Our fair city of New Orleans has ever been rich in the genius and achievements of her medical faculty," said Dr. Beverley Warner; "Stanford E. Chaillé, doctor of medicine, doctor of laws, doctor—the degree is unknown, the power is acknowledged—doctor of men," said the same speaker; "I have never seen any one so impressive in the classroom or who imparted so much knowledge to his pupils as did Dr. Chaillé," said Dr. Lewis S. McMurtry, of Louisville—all in the course of remarks made in the celebration of Dr. Chaillé's completion of fifty years' service in the Medical Department of Tulane University, held in New Orleans on May 19th. Not one of these saying was vainglorious. New Orleans has indeed borne an exalted part in the progress of American medicine, with Dr. Chaillé as *magna pars*.

From the year 1858 up to the present time Dr. Chaillé has served the Medical Department of Tulane University continuously, one might say, for his absence on military duty, whether in the field or on hospital work, also reflected lustre on the university, and his service has been of the most distinguished order. Universities are getting to recognize more and more that their professors' achievements outside the collegiate precincts redound to their renown, and in centuries yet to come Tulane University will plant Chaillé's name higher and higher on its roll of those by whose benefactions it has profited.

It is eminently fitting that Dr. Chaillé's efforts in the service of Tulane University, in the sanitary interests of Louisiana, for the prestige of American

medicine, and for the glory of our profession all over the world, should be commemorated permanently, and it is the intention on the part of the alumni of the Medical Department and their friends that such a commemoration should take the form of a chair endowed in his name. It is to be hoped and confidently expected that this worthy ambition will speedily be realized. At the celebration Dr. McMurtry was introduced as "a distinguished son of Tulane," and we are sure that he could never wish for a more august denomination. The country waits loyally on the triumph of New Orleans, as shown in the general recognition of Dr. Chaillé's career. His declining years are sure to be devoted to the still further advance of medicine. May they also be hal-  
lowed by repose and by reports of continued high achievements by his successors.

THE MECHANICAL FACTORS IN  
LYMPHOCYTOSIS.

F. Peyton Rous (*Journal of Experimental Medicine*, March) contributes an interesting and important paper on the manner of production of lymphocytosis. He finds, from experiments on dogs, that the lymph of the thoracic duct furnishes a large proportion of the lymphocytes to the circulating blood. The number supplied to the peripheral blood through the thoracic duct in the healthy dog is practically constant from hour to hour, if the physiological conditions remain the same. Muscular activity is the most important altered physiological condition affecting the number of lymphocytes. It is accompanied by a prompt increase in the output of lymphocytes through the thoracic duct. This is shown by an increased number of cells in each cubic millimetre of lymph and by an increased amount of lymph voided through a fistula in the thoracic duct. The number of lymphocytes leaving the thoracic duct may be tripled or quadrupled during a long continued struggle, and following this struggle the output of lymphocytes is less for a short time than it was previous to the exertion.

A lymphagogue, such as glucose, also produces an increased flow of lymph and an increased output of lymphocytes through the thoracic duct. While the number of cells to the cubic millimetre of lymph is often low, the total number of cells transported is large. This fact supports the theory of Ehrlich, that a rapidly appearing lymphocytosis may be produced by the flushing effect of an increased flow of lymph. In comparing the lymphocytosis produced by muscular activity and that due to glucose, it is evident that there is some undetermined factor in addition to the increased flow of lymph to be considered in the former.

## THE EMMANUEL CHURCH MOVEMENT IN BOSTON.

The Emmanuel Church movement in Boston, which has resulted in establishing a clinic for the treatment of functional nervous and mental disorders, under the directorship of an able pastor, Dr. Worcester, has assumed such proportions and been so widely exploited that it behooves the medical profession to pause, take an account of stock, and make a careful survey of its objects and methods before concluding as to its worth. This is especially so as many of the leading physicians, both in Boston and elsewhere, have lent the weight of their influence to the movement, and the earnestness, energy, and convincingness of its founder bid fair to make many proselytes.

The rationale of this movement must be based upon the distinction between mind and body, for it is hardly to be supposed that even so great an enthusiast as Dr. Worcester would presume to deal therapeutically with bodily diseases. Even he would probably hesitate to treat a broken hip or a case of typhoid fever. Aside from the very obvious legal objections to such a course, he specifically disavows any intention of dealing with organic disorders, and the physicians who are associated with the movement carefully exclude such, sending him only the so called functional cases.

The priest-physician is not new; he dates back to the primitive social conditions when disease was supposed to emanate from the gods or from evil spirits, and its treatment was therefore closely wrapped up in the current theology. But for the past two thousand years and more the priest, on the one hand, and the physician, on the other, have been gradually differentiated from this early prototype, and by slow increments of change along the line of development of each have become, biologically speaking, distinct varieties. Incidentally, too, it must not be forgotten that the greatest good that has come to the mentally deranged during this time has come from considering them as sick persons, and not as possessed of evil spirits, that the great advances which have taken place in their care and treatment have taken place under the guidance of medicine and not of theology; although only the shortsighted will forget that it was under the influence of the Church that the large humanitarian movements which culminated in the hospitals for the mentally disordered were conceived and carried into execution.

But we are now confronted with another phase of this same type of humanitarian movement, much more restricted in its general scope than were similar movements in the past centuries. The hospitals for the treatment of the sick of body and mind

have passed over almost entirely into purely medical hands. But there are many sufferers from mild and severe functional derangements that need more than the comfort that religion has heretofore given; it must have a dash of science in it, in the form of psychotherapy. Once again, and largely, we believe, on economic grounds, the priest is called upon to enlarge the scope of his work and take upon himself certain attributes of the physician, thus far, without any preparation, save that natural endowment he possesses for influencing the minds of men through emotional agencies—a not to be derided power, let it be understood, particularly in the application of this special feature of the physician's work.

In this Emmanuel movement the clergy are seeking newer fields, and what more promising than the extension of a field in which they have worked for years, but solely as spiritual advisers and comforters? But the flock, becoming immune to the efforts so unceasingly practised, force their leaders to more practical issues, and they turn doctors. One is tempted to draw an analogy, somewhat distorted though it may be. If the water pipe were leaking, would an electrician be sent for to repair it? Perhaps the electrician might be one of those "handy men" who can do anything, and perhaps he would do a good job on the water pipe. But, on general principles, would it not have been the part of wisdom to send for a plumber? Perhaps Dr. Worcester is one of those "handy men," capable, broad gauged, deep of sympathy, who can turn their hands to any task, shoulder any responsibility. Assume that he is, and he really gives that impression, yet he is a priest, and the priest and the physician are as far apart as the aforementioned plumber and electrician. They are two different types of men, their outlook upon life is from different standpoints, their thoughts travel in different paths, their sympathies, ambitions, and aims are different. It is true that at times their paths may cross, that at points their fields of interest may touch, but the principle is not on that account changed.

And herein lies the crux of the situation. Dr. Worcester is not undertaking a strictly personal work, confined by the four walls of his study; he is at the head of a movement, the sponsor for a doctrine which he proclaims from city to city, and as he goes he invites others to take up the work. Is it inherently any more probable that the priests as a class will be any better able to take up the work of the physicians than the electricians as a class are able to do the work of the plumber? Perhaps Boston is seeking another *John* which, though sweet and innocent looking now, may

grow to be a terrible ogre, demanding its human sacrifice through the length and breadth of the land.

We regret that we already know of many attempts which are being made by clergymen, in different parts of this country, men who are no more able to carry out the ideas of Dr. Worcester, much less understand them, than a journeyman plumber can work out the complicated mathematical calculations of an hydraulic problem. The intricacies of the superior psychical mechanisms which constitute the thought processes are not for the untrained mind of the average clergyman as we now know him.

Whatever results may flow from this movement, one of them, it is to be hoped, will be that of arousing the medical profession to a fuller appreciation of its opportunities and responsibilities. The class of patients to whom the Emmanuel Church appeals want help. They have tried in several quarters to get it and failed. They have sought advice of many physicians to little avail. These people will go where help is offered. They had rather get it from legitimate sources, but if not from them, from such as can be obtained. Let the physician see that he himself is equipped to "deliver the goods." If he is not, he cannot complain if his patient goes elsewhere.

It often takes such side stepping from the conventional as this movement is to emphasize certain situations by providing a new setting. The lesson learned, the reason for the movement ceases, and matters move on again in their old accustomed way. For a time the credulous will be misled, but in the end, let us hope, good will result. The way to this result is, not by opposition—martyrdom is a stimulus to growth, bad as well as good—but by taking up the indicated task and by doing it well fulfilling the highest functions of our calling.

#### THE AMERICAN TETANUS ANTI-TOXINE UNIT.

*The Standardization of Tetanus Antitoxine* is the title of a pamphlet, by Surgeon Milton J. Rosenau and Passed Assistant Surgeon John F. Anderson, of the United States Public Health and Marine Hospital Service, recently issued by the bureau. Of the four methods of measuring the strength of tetanus antitoxine—the German, the French, the Italian, and the American—the authors describe the American as the most satisfactory and the simplest of execution. Its application by legal authorization insures identical antitoxic strength in the products of the five American producing establishments, a condition of prime importance in securing uniform-

ity of prophylactic and curative action. The pamphlet furnishes much interesting information concerning many points connected with tetanus, but a satisfactory abstract of it cannot well be given within the space now at our command. It is a very scholarly production, and we commend it to our readers.

#### THE MILK SUPPLY OF NEW YORK.

The New York City Board of Health has recently announced that hereafter only certain specified terms will be allowed to be used in the local milk traffic, and each term will have a definite meaning. Practically, three grades are recognized—certified, inspected, and ordinary milk. Instead of leaving the definition of the first two terms entirely to the milk commissions of the county medical societies, the board has—wisely, we think—laid down a minimum of requirements to be met. The use of the term "pasteurized" is also regulated by the board, and this, it is to be hoped, will do away with a lot of trading under false pretenses. It is notorious that a great deal of "pasteurized" milk is merely milk several days old heated to 150° F. for several seconds to prevent it from souring. Such milk, however, has frequently been put forward by dealers as something superior because "pasteurized."

The board has also legalized the sale of skimmed milk, but under restrictions. It is generally recognized that skimmed milk possesses considerable nutritive value, and the only objection to its sale is the ease with which deception can be practised, skimmed milk being sold for whole milk or being mixed with whole milk. Berlin recognizes whole milk, half milk, and skimmed milk. It is hard to say just how well this works, even in that city. Certainly the general quality of the Berlin milk is far below that of the milk sold in New York.

#### CHEYNE-STOKES RESPIRATION.

Since the time when Cheyne and Stokes described the peculiar phenomenon which has since gone by their combined names, from patients suffering with fatty degeneration of the heart, much physiological and pathological interest has been taken in this type of breathing, and a gradual modification of the significance to be attached to it has taken place. It is now well known that Cheyne-Stokes respiration is not necessarily a pathological type of breathing. Not only do cold blooded animals show it regularly as a physiological type, but there is present in many mammals under certain normal conditions a type of respiration which cannot be distinguished from the Cheyne-Stokes respiration known to the clinician.

This periodic type of breathing is seen in the winter sleep of the marmot, the hedgehog, and the dormouse, and in many mammals, when great diminution of nervous excitability takes place, typical Cheyne-Stokes breathing supervenes. In young and healthy sleeping infants a periodic type of breathing of a similar order is frequently observed, and even in many healthy adults Cheyne-Stokes respiration is present in deep sleep. In all these conditions a marked diminution in nervous excitability is naturally present.

The changes in the activity of the respiratory centres have been ascribed to the composition of the blood, and it is to a combination of these two conditions that modern physiologists have attributed the phenomenon. All the cases of Cheyne-Stokes respiration, physiological as well as pathological, are accompanied by a decrease in the excitability of the nervous system. The phenomenon in pathological cases is not characteristic of any particular disease, and it is not necessarily a fatal omen; it is a sign of diminished nervous excitability, and is very frequently associated with a defective supply of arterial blood to the brain. The different phases of Cheyne-Stokes respiration appear to arise in the following manner: The carbon dioxide accumulates and the oxygen diminishes until the depressed nerve cells are stimulated; the first respirations are shallow and inefficient, and, owing to the delay necessary for the renewal of the air in the lungs and the passage of blood from the lungs to the brain, the carbon dioxide still increases and the oxygen decreases. Thus arises the waxing respiration, which culminates in deep dyspnoic breathing; carbon dioxide is removed in great quantities from the blood, and sufficient oxygen is taken in; the stimulation becomes less and less and respiration wanes. Then follows apnoea, due apparently to the absence of sufficient carbon dioxide to excite the respiratory centre. On account of the latency already mentioned, the most arterial blood will reach the medulla at the end of the breathing period, and at the same time the blood pressure will have been raised by the pumping effect of the deep respiration.

### News Items.

**Changes of Address.**—Dr. Matthias Lanckton Foster, to 211 Centre Avenue, New Rochelle, N. Y.; Dr. Edward A. Schumann, to 348 South Fifteenth Street, Philadelphia; Dr. Collier L. Bower, to the Dardinelle, Broad and Locust Streets, Philadelphia.

**The Philadelphia Medical Club** will hold a reception at the Bellevue Stratford Hotel on the evening of June 10th. The guests of honor will be Dr. William L. Ewing of South Bethlehem, Pa., president of the Medical Society of the State of Pennsylvania, and Dr. Albert M. Freeman of Philadelphia, president of the Philadelphia County Medical Society.

**Vacancies in the Medical Corps of the Navy.**—There are fifty-four vacancies in the grade of assistant surgeon in the Navy and sixteen vacancies in the grade of acting assistant surgeon. The board will meet on June 1st for the examination of candidates.

**A Chair in Phthisiotherapy at the Postgraduate.**—A chair in phthisiotherapy has been created at the New York Postgraduate Medical School and Hospital, and Dr. S. Adolphus Knopf, of New York, has been appointed professor of phthisiotherapy to fill the chair.

**Medical Society of Otsego County, N. Y.**—The semi-annual meeting of this society will be held in Cooperstown on Tuesday, June 9th. The programme will include a "symposium" on adenoids and throat tumors, and a general discussion of hyosine, morphine, and cactin in surgery.

**The Lawrence, Mass., Medical Club** held its regular monthly meeting at the residence of Dr. Burnham on the evening of May 25th. The general subject for consideration was scarlet fever, and after the usual half hour talk on miscellaneous medical topics, the discussion was opened by the chairman, Dr. Allen. At the close of the meeting refreshments were served.

**Appointments at Albany Medical College.**—Dr. Andrew McFarlane has been appointed professor of physical diagnosis and medical jurisprudence at this college; Dr. Arthur G. Root has been appointed professor of diseases of throat and nose; and Dr. Leo H. Neumann has been appointed professor of gastroenteric diseases and clinical professor of the theory and practice of medicine.

**The Red Cross to be Taken from Ambulances.**—The Red Cross Society objects to the use of the red cross on city ambulances, on the ground that the society has the exclusive right to the use of the emblem, having copyrighted it in all civilized countries. Consequently the red cross will be removed from all the ambulances of the hospitals, and a green symbol will be used in its place.

**Richmond, Va., Academy of Medicine and Surgery.**—A regular meeting of this academy was held on Tuesday evening, May 26th. Dr. Edward McGuire read a paper on Prolapse of the Ovary, and Dr. J. Shelton Horsley read a paper entitled Technique of Operations on the Mouth and Neck. Dr. Ramon D. Garcin opened the discussion on Dr. McGuire's paper, and Dr. J. W. Henson opened the discussion on Dr. Horsley's paper.

**American Medical Editors' Association.**—The programme for the thirty-ninth annual meeting of this association, which is to be held at the Auditorium Hotel, Chicago, May 30th and June 1st, has just been received. It contains twenty-two papers by well known medical editors, and a list of subjects which will be announced for discussion if time permits. The annual banquet of the society will be held at the hotel on Monday evening, June 1st.

**Personal.**—Dr. John H. McCollum has been appointed professor of contagious diseases at the Harvard Medical School. Dr. McCollum was city physician for Boston for many years and superintendent of the contagious disease department of the Boston City Hospital.

Dr. J. C. Nicholls, of Braddock, Pa.; Dr. W. M. Jones, of Omaha, Neb., and Dr. Robert B. Knight, of Coudersport, Pa., are registered at the Philadelphia Polyclinic and College for Graduates in Medicine.

**Vacancies in the Army Medical Corps.**—Examinations were recently held in various parts of the country of candidates for appointment as assistant surgeon to fill the sixty-eight vacancies now existing in the corps. Seventy-two candidates applied for the examination, sixteen failed to continue, and the papers of the remaining thirty-eight were being examined. Examinations will be held again in October for the same vacancies.

**Philadelphia County Medical Society.**—The Central Branch of this society held a meeting on the evening of Wednesday, May 27th. Mrs. I. B. Oakley presented a short communication on the plan of establishing "zones of quiet" in the neighborhood of hospitals, and among those who attended were Dr. W. M. Jones, superintendent of the Polyclinic Hospital, and Dr. W. M. Jones, superintendent of the Polyclinic Hospital. Dr. W. N. Bradley read a paper on Diphtheria, and Dr. W. N. Bradley read a paper on Diphtheria.

**A Department of Mechanicotherapeutics at Vanderbilt Clinic.**—As a memorial to her late husband, Mrs. Ray Matshak has given the money necessary to equip a department for surgical mechanicotherapeutics at the Vanderbilt Clinic of the College of Physicians and Surgeons. Columbia will be the first university in the United States to have such an equipment. Dr. Charles H. Jaeger, instructor in orthopaedic surgery at Columbia University, will have charge of the department.

**Officers of the American Neurological Association.**—At the annual meeting of this association, which was held in Philadelphia on May 21st, 22d, and 23d, the following officers were elected: President, Dr. S. Weir Mitchell, of Philadelphia; first vice president, Dr. Pierce Bailey, of New York; second vice president, Dr. F. W. Langdon, of Cincinnati; secretary and treasurer, Dr. Graeme Hammond, of New York; councilors, Dr. H. W. Thomas and Dr. Charles W. Burr, of Philadelphia.

**Alumni Association of Jefferson Medical College.**—The annual meeting of this association will be held in the college building at 12 o'clock on June 6th, and the annual banquet will be given in the ballroom of the Bellevue-Stratford Hotel in the evening of the same day. The balcony of the banquet room has been reserved for ladies. A grand rally of graduates of the college will be held in Chicago during the meeting of the American Medical Association on the evening of June 2d at the new Chicago Automobile Club.

**Samaritan Hospital, Philadelphia, Medical Society.**—At a meeting of this society, which will be held on Saturday evening, May 30th, at 9 p. m., the programme will include the following papers: Ocular Signs of Toxæmia in Diabetes, by Dr. Wendell Reber; The Theory and Application of Bier's Hyperæmic Treatment, by Dr. William A. Steel; A Study in Anæsthetics, and a Demonstration of the Surgical Pathology of the Gallbladder, by Dr. W. Wayne Babcock; Benign Strictures of the Rectum, by Dr. C. Howard Pratt; Report of the Work of the Genito-urinary Department of the Hospital, by Dr. H. G. Fretz; Report of a Year's Work by the Surgical Staff, by Dr. John Leedon.

**Vital Statistics of New York.**—During the week ending May 16, 1908, there were reported to the Department of Health 1,465 deaths from all causes, as compared with 1,471 for the corresponding period in 1907. Of the total number of deaths 762 were in Manhattan, 134 in the Bronx, 475 in Brooklyn, 66 in Queens, and 28 in Richmond. The annual death rate in 1,000 of population was 17.28 for the whole city, 17.62 for Manhattan, 19.47 for the Bronx, 18.12 for Brooklyn, 16.77 for Queens, and 19.37 for Richmond. The total infant mortality for the week was 384; under one year of age, 300; between one and two years of age, 84. There were 143 still births. There were 406 marriages recorded during the week and 2,287 births.

**Scientific Society Meetings in Philadelphia for the Week Ending June 6, 1908:**

**MONDAY, June 1st.**—Philadelphia Academy of Surgery; Biological and Microscopical Section, Academy of Natural Sciences; West Philadelphia Medical Association; Northwestern Medical Society.

**WEDNESDAY, June 3d.**—College of Physicians; Association of Clinical Assistants, Wills Hospital.

**THURSDAY, June 4th.**—Obstetrical Society; Section Meeting, Franklin Institute; Germantown Branch, Philadelphia County Medical Society.

**FRIDAY, June 5th.**—Kensington Branch, Philadelphia County Medical Society.

**New York Academy of Medicine.**—At a stated meeting of the academy, which was held on Thursday evening, May 21st, the following papers were read: The Hospital and the Professional Anæsthetist, by Dr. A. T. Bristow; General Anæsthesia on the Basis of the Principle of Adapting the Boiling Point of the Anæsthetic to the Temperature of the Body, by Dr. Willy Meyer; The Anæsthetic at the Hospital for the Ruptured and Crippled, by Dr. Virgil P. Gibney; Anæsthesia at St. Luke's, by Dr. Robert Abbe; The Scope of Local Anæsthesia in General Surgery, by Dr. J. A. Bodine; The Administration of Anæsthetics at Mt. Sinai Hospital, by Dr. Howard Lilienthal; Rectal Anæsthesia at Roosevelt Hospital, by Dr. J. A. Blake and Dr. George E. Brewer; Anæsthesia at the Harlem Hospital, by Dr. William H. Luckett; Anæsthesia at Bellevue Hospital, by Dr. George Woolsey; Nitrous Oxide and

Oxygen as an Anæsthetic Agent, with Notes on the Value of Warming the Vapors of Ether and Chloroform, by Dr. James T. Gwathmey.

**The Mortality of Chicago.**—According to the weekly report of the Department of Health, during the week ending May 16, 1908, there were reported to the department 635 deaths from all causes, as compared with 531 for the preceding week, and 707 for the corresponding period in 1907. The annual death rate, in an estimated population of 2,166,055, was 15.29 in 1,000 of population. The principal causes of death were: Apoplexy, 23; Bright's disease, 42; bronchitis, 18; consumption, 63; cancer, 42; convulsions, 8; diphtheria, 3; heart diseases, 57; influenza, 5; intestinal diseases, acute, 35; measles, 5; nervous diseases, 10; pneumonia, 74; scarlet fever, 10; smallpox, 0; suicide, 8; typhoid fever, 11; violence (other than suicide), 46; whooping cough, 8; all other causes, 158.

**Secretaries of Sections of the Fifth Pan-American Medical Congress.**—Secretaries for the United States of the various sections of this congress, which is to be held in Guatemala City, Guatemala, on August 5th to 10th, inclusive, have been appointed as follows: General Medicine, Dr. Judson Daland, of Philadelphia; General Surgery, Dr. Emmett Rixford, of San Francisco; Hygiene, Demography, and Epidemiology, Dr. T. Darlington, of New York; Nervous and Mental Diseases, Dr. Charles Hughes, of St. Louis, Mo.; Tropical Medicine, Dr. John M. Swan, of Philadelphia; Military Sanitation, Dr. L. L. Seaman, of New York; Ophthalmology, Dr. Bert Ellis, of Los Angeles, Cal.; Nose, Throat, and Ear, Dr. W. S. Bryant, of New York; Pathology and Bacteriology, Dr. Walter Chase, of Boston; Gynecology, Abdominal Surgery, and Obstetrics, Dr. H. P. Newman, of Chicago; Children's Diseases, Dr. C. G. Kerley, of New York.

#### Infectious Diseases in New York:

*We are indebted to the Bureau of Records of the Department of Health for the following statement of new cases and deaths reported for the two weeks ending May 23, 1908:*

	—May 16th— Cases.	Deaths.	—May 23— Cases.	Deaths.
Tuberculosis pulmonalis	413	158	420	201
Diphtheria	409	39	397	37
Measles	1,514	35	1,455	33
Scarlet fever	1,073	41	1,053	40
Smallpox	1	..	..	..
Varicella	134	..	144	..
Typhoid fever	25	6	32	6
Whooping cough	37	4	24	4
Cerebrospinal meningitis	13	11	12	9
Totals	3,768	291	3,637	328

**The Harvey Society.**—At the annual meeting of this society, which was held on Friday evening, May 15th, the following officers were elected: President, Dr. James Ewing; vice president, Dr. Simon Flexner; treasurer, Dr. Edward K. Dunham; secretary, Dr. F. C. Wood; council, Dr. Graham Lusk, Dr. S. J. Meltzer, and Dr. Adolph Meyer. The following resolution was adopted by the society:

*Resolved, That, in the desire of Dr. Graham Lusk not to undertake again the duties of president of the Harvey Society, its members express to him their cordial appreciation of the great value of his services to the medical sciences in this country in founding the society, in successfully administering its affairs during its early growth, and in placing it upon a substantial basis. The place now occupied by it abundantly demonstrates the wisdom of Dr. Lusk in organizing a medium of communication between the laboratory and the medical practitioners; and whatever the society shall accomplish in the future will be due in no small part to the worthy example which he has set.*

**International Congress on Tuberculosis.**—President Roosevelt has accepted the presidency of the International Congress on Tuberculosis, which is to be held in Washington, September 21st to October 12th. Dr. Edward L. Trudeau, of Saranac, N. Y., has been elected honorary president of the congress, and among those who have agreed to serve in the capacity of vice presidents are Vice President Fairbanks, Speaker Cannon, and the Governors of the States of California, Colorado, Connecticut, Illinois, Indiana, Iowa, Kansas, Kentucky, Maine, Maryland, Michigan, Minnesota, Mississippi, Missouri, New Hampshire, New Jersey, New York, North Carolina, North Dakota, Ohio, Oregon, Pennsylvania, South Carolina, Tennessee, Vermont, Virginia, and West Virginia. The German committee of arrangements for the congress has a membership of over one hundred and fifty, and the names of some of the highest dignitaries in the Empire appear

**Queens-Nassau Medical Society.**—The annual meeting of this society was held in Jamaica, Long Island, on the evening of Saturday, May 23d. It was one of the most successful meetings ever held by the society. There were about eighty members in attendance, and the papers, which were all of a high order, were listened to with much interest. Dr. T. D. Crothers, of Hartford, Conn., read a paper entitled Home and Office Treatment of Spirit and Drug Takers, after which a "symposium" on midwifery was presented as follows: The Conduct of Normal Labor, by Dr. Charles Jewett, of Brooklyn; Eclampsia, by Dr. J. Clifton Edgar, of Manhattan; The Action of Forceps, by Dr. James D. Trask, of Highlands, N. J.; Version—When Shall We Prefer it to Forceps? by Dr. W. G. Frey, of Long Island City; The Art of Pelvimetry, by Dr. Sidney O. Polak, of Manhattan; Cesarean Section, by Dr. John O. Polak, of Brooklyn; Post Partum Plastic Repair, by Dr. Grant Baldwin, of Brooklyn; Morbidity and Mortality in Cases of Labor in Brooklyn, by Dr. J. C. Brainerd. A committee was appointed to receive applications for admittance, and for the coming year the following officers were elected as follows: President, Dr. C. M. Nichols; Vice-President, Dr. P. M. W. Jones; Secretary, Dr. James S. Calkins; Treasurer, Dr. Walter Landay; Librarian, Dr. J. C. Brainerd; Dr. W. G. Frey, of Long Island City; Dr. A. J. Blanchard, of Jamaica; Dr. A. W. Jones, of Brooklyn; Dr. J. T. Carr, of Rockville Centre; and Dr. C. F. Chapman, of Mineola.

### THE BOSTON MEDICAL AND SURGICAL JOURNAL.

May 21, 1908.

1. Social Legislation in Germany and Its Relation to the Practice of Medicine, By FRIEDRICH MÜLLER.
2. Certain Common Disorders Frequently Misinterpreted, By GEORGE L. WALTON.
3. Medical Notes on Northern Alaska, By S. P. HOWE.
4. Varicose Veins of the Papilla of the Kidney. A Cause for Persistent Hæmaturia, By WILLIAM F. WHITNEY.

3. **Medical Notes on Northern Alaska.**—Howe has spent a year on the north coast of Alaska. He makes some interesting notes: The Eskimo race in Alaska has greatly diminished in numbers in the past twenty years, in a large part because of disease inevitably introduced by the whites. Whether the race will acquire sufficient immunity to withstand this sort of thing time alone will tell. He thinks the outlook for the Eskimo in his natural condition is better than that of the North American Indian, because the Eskimo is industrially valuable to the whites in the extreme north. The Eskimo, while useless for steady day labor, is docile and satisfactory as a hunter and trapper. He makes a good sailor on a whale ship, and is practically necessary to the men engaged in floe whaling. Tuberculosis is the great plague of the country. It was present, so he was told, when white men first came into the country. In summer the patients with pulmonary disease improve markedly while living out of doors, only to relapse again in winter. Venereal disease is less common now than formerly, as the natives come in somewhat less contact with the crews of the whale ships. Very soon after the settlement of Nome an epidemic of measles swept up the coast with frightful mortality. Many who recovered fell victims to pneumonia and phthisis. This epidemic carried off nearly half the inhabitants of some of the villages. A disease, similar to, if not identical with, influenza, is endemic at Point Barrow. Formerly, at the time of childbirth, a woman retired to a separate house or tent to have her child. No one entered the house or offered any assistance. Now, frequently, other women are present, and, if there is any trouble, the help of a white man is welcomed. When twins are born, if it seems feasible, both are raised, if not, one is exposed to die. The natives are sorry to do it, but take it calmly as a matter of course. A woman nurses her child as long as she is able, or till another child is born. This is rather necessary, as native food is not very satisfactory for weaning a young child. It is not an uncommon thing to see children three and four years old nursing. A large infant mortality, due to improper feeding, makes large families the exception. A child is allowed to eat anything its parents do. Abortion is occasionally practised, by means of violent abdominal massage, but is not common, as, generally speaking, children are desirable assets. The staple food of the coast Eskimo is seal meat, summer and winter, though whale, deer, bear, fish, and ducks are important in their seasons. Though the primitive Eskimo diet was almost entirely ani-

mal, at present most reasonably prosperous natives get considerable tea, flour, sugar, and tobacco. In fact, the children suffer considerably if deprived of flour and sugar now.

1. The Prevalence of Cancer in the Philippine Islands, By F. W. DUDLEY.
2. The Cause of Milksickness or Trembles, By EDWIN O. JORDAN and N. M. HARRIS.
3. Surgery of the Prostate. A Plea for Early Prostatectomy in Hypertrophy of the Prostate, By MILES F. PORTER.
4. Hypertrophy of the Synovial Fringes of the Knee Joint, By EDVILE GERHARDT ABBOTT.
5. Hip Joint Tuberculosis: Its Earlier Symptoms and Treatment, By WILLIAM THOMPSON BERRY.
6. Serum Treatment of Gonorrhœa, with Report of Cases, By ROBERT H. HERBST.
7. Spinal Sprain: Its Complications and Consequences, with Report of Cases, By PRESCOTT LE BRETON.
8. Are There Valid Objections to the Quinine Prophylaxis of Malaria? By E. R. STITT.
9. Psychic Treatment of Spirit and Drug Neuroses, By T. D. CROTHERS.
10. Pathological Results of Operations on the Turbinates, By FRANCIS R. PACKARD.

1. **The Prevalence of Cancer in the Philippine Islands.**—Dudley concludes from his observations that cancer is not confined to temperate climates. It is believed that cancer exists in the Philippine Islands to a greater extent than in the United States. The measures now being taken in other more enlightened countries to warn the people of the necessity of early diagnosis, and early radical surgical treatment in this disease, should be adopted in the Philippine Islands, where it is of sufficient importance to warrant an effort being made to obtain better statistics in the future.

2. **The Cause of Milksickness or Trembles.**—Jordan and Harris describe a peculiar disease, now all but forgotten both by physicians and the general public, which prevailed extensively in certain sections of the United States during the years of pioneer settlement. This disorder was known under a great variety of names, but was most commonly referred to as milksickness, from its apparent connection with the use of milk and milk products. A singular feature of the disease was its geographic limitation, the States of Ohio, Indiana, Illinois, Kentucky, and Tennessee covering the area chiefly affected. The medical journals of the western States, in the period of from 1840 to 1860, contain numerous articles on the disease, but coincident with the clearing and cultivation of the land milksickness has tended to disappear, and except for its sporadic appearance in certain localities, has become practically extinct in those States in which it was once a barrier to settlement. Cases, however, have occurred in Illinois as recently as 1904, and six deaths were reported from this cause in Macon County, Tennessee, in April and May, 1907. The chief symptoms of the disease are usually persistent nausea and vomiting, which led to the use of the name "sick stomach" in some localities. Obstinate constipation is an almost invariable accompaniment of the malady. A peculiar odor of the breath, usually described as "sweetish," is commonly noted and is regarded as highly characteristic by those having

most experience with the disease. Muscular weakness, abdominal pain, and other symptoms are more or less frequently reported. In the more severe cases great prostration occurs. As a rule, little or no fever is present, and the temperature is said sometimes to be subnormal. The authors discovered, in November, 1907, a new form of milksickness in the valley of the Pecos river, New Mexico; the death of cattle was generally attributed to alkali poisoning. The authors have made many observations and autopsies on cattle and received from local physicians the reports of thirty-eight cases in man. They found a bacillus in cattle which they designated *Bacillus lactimorbi*. It is a little smaller than the anthrax bacillus, larger and more slender than the colon bacillus, and stains unevenly with methylene blue; spore formation was seen, which was similar to the effect of the tetanus bacillus; the organism is motile, is possessed of ten or fifteen flagella, the flagellum measuring about five times the length of the bacillus itself. Some conjectures have been made as to aetiology, but nothing definite can be said.

**6. Serum Treatment in Gonorrhoea.**—Herbst thinks that the serum has absolutely no effect on acute gonorrhoeal infections, whether they exist in the lower urinary tract or in any other part of the body. Its value in subacute and chronic cases is very doubtful, although he found a few isolated cases in which the results were somewhat better than seen with local treatment, but its value in the treatment of chronic gonorrhoeal joints is without question. In the past, these painful joints accompanying and following gonorrhoea have been most resistant to treatment, both local and general, and he thinks that we now have a remedy which will give rapid and permanent relief. The antgonococcus sera used by Herbst were made according to the method described by Rogers and Torrey. Cultures are grown\* for from eighteen to twenty-four hours on large slants of ascitic agar. Culture tubes average one inch in diameter. It is essential to obtain a luxuriant growth. This is best accomplished by planting from an eighteen to twenty-four hour stock culture to medium of the following composition: Meat peptone 2 per cent. agar is prepared in the usual way and triturated 1.5 per cent. acid to phenolphthalein. One part of rich sterile ascetic fluid is then added to two parts of the agar. The full grown uncastrated male sheep (the ram) only is used. In immunizing these animals it has been found advantageous to pursue the following plan: The first inoculation may consist of the twenty-four hour surface growth, from eighteen square inches of solid culture medium, emulsified in about 30 c.c. of normal saline solution and heated for about one half hour at 65° C. In immunizing rabbits and goats, a potent serum was obtained, but it was found that the serum itself is decidedly toxic for some individuals and produced rather alarming reactions; hence, only rams are used. The immunization of the ram requires ten weeks, one injection being given weekly. The animal is bled to death from the carotid and the serum collected, filtered, and tested for sterility. The serum is polyvalent. The method of administration is by subcutaneous injection, the skin being

prepared as for other subcutaneous injections. The abdominal wall was used in all his cases, because the reaction which follows almost every injection is better tolerated in this part of the body. The amount given at each injection varied from 2 to 6 c.c. The injections were given from forty-eight hours to seven days apart, depending on the severity of the reaction. A reaction followed almost every injection, appearing sometimes in the form of a slight urticaria at the site of the injection, at other times in a more severe form accompanied by a dermatitis, enlargement of the inguinal glands, rising of temperature from one to two degrees, and an increase in the pulse rate. Most of these symptoms disappeared in from twenty-four to forty-eight hours. In one case, however, the urticaria and dermatitis extended over the entire body, with a high temperature and rapid pulse, and continued for nearly five days. The absorption of the serum was rapid; the tumor which followed the injection disappeared in about fifteen minutes.

**7. Spinal Sprain.**—Le Breton remarks that rest in bed, with counterirritation to the spine, is effectual in the severe types of sprain. A plaster jacket for several weeks is the most comfortable and rigid splint, to be followed by a removable leather or celluloid jacket. It is most strongly indicated where there is spasm, but also is often indicated where there is only pain on motion, or in cases where there is no pain but where cord symptoms are developing. In neurotic cases a light temporary support acts favorably. There is not the same danger of prolonged stiffness following, such as may result from fixation of a sprained ankle. Massage, exercises, and avoidance of lifting, bending, and riding in cars are in order later on. The support is left off at night, and a small pillow is placed under the small of the back to fix the lumbar curve. For spasm of the neck muscles, head traction in bed, followed by a jacket with a head support, brings prompt results. The injury that originates a true sprain of the spine is more often indirect than direct. In seventeen of his twenty-six cases the cause was a fall on the buttocks, a fall on the feet, prolonged lifting, or a violent wrench of the body, causing sudden flexion of the spine. In nine of the cases the cause was direct violence to the back itself. The site of trouble is more often at the lumbodorsal region than at that other movable section, the lower part of the neck. In nineteen of the cases the lumbar portion of the spine was affected, and in seven the lower cervical. Brush, in a collection of forty-three cases, found the condition located in the lumbar region in thirty-eight of them. The outlook for recovery is much better if the diagnosis is prompt and treatment is instituted early. When fixation by jacket is indicated by great pain or spasm, it is most unwise to defer it. Brush states that in fourteen cases in which the diagnosis was made at once and proper treatment begun, there were eight full recoveries. Whereas in twenty-nine cases with delayed diagnosis and treatment, there were but two recoveries. In general, it is much better to settle an annoying suit rather than to wait for trial, but settlement should be deferred until one can feel sure about the future condition of the patient.

## MEDICAL RECORD.

May 23, 1908.

1. A Clinical Study of a Case of Brain Tumor; Operation; Complete Recovery, By WILLIAM W. GRAVES.
2. Pneumothorax and Posture; the Importance of the Abdominal Posture in Operations on the Pleura and Lungs, By CHARLES A. ELSBERG.
3. A Report of Thirty-one Cases of Congenital Dislocation of the Hip Joint Reduced by Manipulation, By EDVILLE GERHARDT ABBOTT.
4. Sources of Error in Gastric Diagnosis, By CHARLES SUMNER FISCHER.
5. Prevention and Treatment of Cystitis, By PAUL PILCHER.

1. **A Clinical Study of a Case of Brain Tumor.**—Graves observes that brain tumor is usually localizable; therefore, an early and localizing diagnosis is always desirable if complete restoration is to be hoped for. If palliation alone is to be expected, precise localization is not absolutely necessary though always desirable. It may be stated, however, that tumor of the brain giving rise to symptoms indicating palliation will usually present unmistakable localizing symptoms. The presence of brain tumor, its location, its probable nature, and the surgical indications, whether extirpation or mere palliation, are problems the surgeon has a right to expect—the neurologist to attempt to solve. On the other hand, the neurologist expects, and the interest of the patient requires, the surgeon to be possessed of a degree of technical skill commensurate with the difficulties constantly met with in this field of work. The ideal would be a surgeon who is at the same time a neurologist. The difficulties encountered in surgery of the nervous system are so great that it is rapidly becoming, and justly so, a special department of surgery. He who would do this work should have had some special training—not only special technical training, but also in the physiology, anatomy, and pathology of the central nervous system—in other words, he should have given the whole subject his earnest consideration before invading the brain or spinal cord with the same degree of assurance that he would the abdominal cavity. The surgeon and the neurologist are indispensable to each other at the present time in surgery of the nervous system. It is a field wherein they should both work shoulder to shoulder, and when it is tilled with earnestness and mutual consideration, their joint labor can only have the result of saving or prolonging many lives.

2. **Pneumothorax and Posture.**—Elsberg says that the danger of the sudden entrance of air into the normal pleural cavity has, more than anything else, impeded the progress of the surgery of the lung and of the other intrathoracic viscera. There are other dangers, such as that of great susceptibility to infection, but the grave symptoms from acute pneumothorax are those that have to be most considered. Much careful experimental and clinical work has been done to overcome and guard against the dangerous respiratory embarrassment which is apt to ensue. He reports the experiments made by others and by himself. His results were then applied on patients. All of these patients upon whom operations were performed which required the opening of the pleura, were operated upon lying flat on the abdomen. Care was taken that the patients were deeply under the anæsthetic at the moment when

the pleura was opened. Operations on the lateral or posterior aspects of the thorax could be done with ease. The patient was laid flat on the belly with the head turned to one side or supported beyond the end of the operating table so that the anæsthesia could be given without trouble. The position did not interfere with the operator or assistants. In this posture he has operated upon a large number of patients with empyema, upon two patients with abscess of the liver, upon three with subphrenic abscess, and upon one with a bronchiectatic cavity in the left lung. In all of the last named patients the pleura had to be opened. The patients in whom a normal pleura had to be opened showed unusually few untoward symptoms when the opening was made and air was allowed to enter the pleural cavity. In the patients upon whom an operation for empyema was done, it was noted that with only one exception the coughing and interference with breathing, regularly observed when the opening in the pleura is made for this affection, were entirely absent. While these cases are too few to be conclusive, remarks the author, they seem to demonstrate that what is true for dogs is also true in this respect for the human being, and that there are decided advantages in operating upon these patients in the abdominal posture. He believes that those who try this simple procedure will soon appreciate its manifest advantages. It is a very simple method of safeguarding our patients a little more in our intrathoracic operations, and may be used in conjunction with other methods.

## BRITISH MEDICAL JOURNAL.

May 9, 1908.

1. The Diagnosis and Operative Treatment of Diseases of the Stomach, By B. DAWSON.
2. Gastroenterostomy and After, By B. G. A. MOYNIHAN.
3. Erythrocythæmia and Cyanosis, By W. P. HERRINGHAM.
4. The Recognition and Training of Congenital Mental Defectives, By W. A. POTTS.
5. An Outbreak of Beriberi on Board a Merchant Vessel, By S. ROACH.
6. Treatment of Bronchial Catarrh by Alkalies, By A. HAIG.
7. The Influence of Pregnancy upon Certain Medical Diseases and of Certain Medical Diseases upon Pregnancy (Goulstonian Lectures, II), By H. FRENCH.

1. **Surgery of the Stomach.**—Dawson discusses the diagnosis and surgical treatment of various affections of the stomach. In malignant disease of the œsophagus gastrostomy may prolong life, but will prolong misery also. Unless and until there is some definite urgent symptom like thirst calling for relief, the operation should be avoided. In most cases the body is able to obtain enough water and enough nourishment. The operative treatment of cancer of the stomach comprises excision and gastroenterostomy. Where the disease is discovered early enough, the results of excision are promising. Gastroenterostomy does palliate suffering where there is pyloric obstruction, but the immediate mortality is not less than twenty-five per cent., and in prolonging life the suffering is prolonged. Even where an exploratory operation has been done, gastroenterostomy should be advised against unless there is some definite object to be gained. But where the pylorus is obstructed by a hard, circum-

scribed growth, the advantage of providing an exit for the food outweighs the risk. But even then lavage often gives better results. Pain is often not a prominent early feature of cancer; in contrast to this, absence of actual pain in gastric ulcer is almost unknown, and if there is vomiting it follows this pain. Stomach discomfort in an adult over thirty who has previously had a good digestion, and without obvious cause, calls for further investigation, consisting of: (1) Inflation of the stomach with gas to see if it is enlarged or prolapsed; (2) passage of a tube eight hours after an ordinary meal to see if the stomach is empty; (3) analysis of the gastric contents after a test meal; and (4) microscopical examination of the fasting stomach contents. Acute perforation of a gastric ulcer calls for immediate operation. The operative treatment of subacute and chronic ulcer resolves itself into a study of the benefits to be expected from gastroenterostomy. These benefits are: (a) Diminished acidity when the stomach is quiet in the intervals of digestion; (b) the evils of pyloric spasm are eliminated; (c) the intra-gastric pressure is kept lower, and therefore the movements and tension of the stomach wall are less. The diagnosis of gastric ulcer is often made only with the greatest difficulty. Many cases, previously thought to be ulcer, are now recognised not to be ulcer at all. Such cases fall into two main groups. First, the cases of pain and vomiting after food, occurring exclusively in anemic young women. The symptoms improve rapidly when the patients are put to bed, and solid food and iron are tolerated from the first. Another group of cases is called by the writer "hæmorrhagic gastralgia." Here the clinical symptoms are identical with those of ulcer. As regards operation in cases of hæmatemesis, in order to ligate the bleeding points, the writer puts forward an emphatic negative. The operation is necessarily severe, involving traction on the stomach, and this at a time when the patient is exhausted by loss of blood. There may be and often are multiple points of hæmorrhage, and to place sutures around such points is almost futile. Finally, medical treatment of hæmatemesis is successful, and the mortality is but little more than three per cent. In cases of atonic or nonobstructive dilatation of the stomach, gastroenterostomy is rarely necessary or desirable; failure of motor power is usually responsible for non-success. In a few cases where there is marked gastroptosis, with almost kinking of the stomach, gastroenterostomy might conceivably be of service. But medical treatment is usually satisfactory. It should consist of careful dieting to make the work of the stomach as light as possible, of careful massage, of keeping the patient in as good condition as possible, of drugs like strychnine, and of periods of rest on a bed or couch the foot of which is elevated.

2. **Gastroenterostomy.**—Moxon's conclusions are as follows: 1. Gastroenterostomy is a short circuiting operation, and like all such procedures, acts best when a gross mechanical obstruction exists in the normal path of the intestinal contents. 2. Experiment shows that when the pylorus is normal, and there is no impediment to the passage of food through it, the opening made in the operation of gastroenterostomy does not allow of the escape

of any of the gastric contents into the intestine. 3. The operation therefore gives the best results in cases where there is organic disease in the prepyloric or pyloric regions of the stomach or duodenum, or when performed on the cardiac side of a stenosis in the body of the stomach. 4. When an ulcer is found on the lesser curvature toward the cardia it should be excised if possible; gastroenterostomy is not necessary, and if performed is either almost useless or entirely harmful. 5. When there is a suspicion of malignancy in an ulcer or ulcers in the pyloric region, Rodman's operation should be performed. 6. Under no circumstances, and in compliance with no persuasion, however insistent, is gastroenterostomy to be done in the absence of demonstrable organic disease. 7. Regurgitant vomiting, formerly the most troublesome of all complications, is dependent upon faults in the operation which result in some mechanical obstruction to the intestine. These faults are chiefly dependent upon the presence of a "loop" in the jejunum, but may also be caused by a twist in the intestine around its longitudinal axis at the time of its application to the stomach. 8. The posterior no loop operation with the vertical application of the bowel to the stomach is the best procedure.

## LANCET

8. The Nursing Difficulty in France, By J. DARDEL.

1. **Pregnancy in its Relation to Diseases.**—French, in the second of his Goulstonian lectures, considers the influence of suppurative calculous and tuberculous affections of the kidney on pregnancy. He reports one case in which the sequence of events was renal calculi, hydronephroses, pregnancy, microbial infection of the kidneys, pyonephroses, suppurative pyelonephritis, cystitis, uræmia, and death. Tuberculosis of the kidney and pregnancy are practically never associated. As regards nonsuppurative renal affections, it is clear that pregnancy will have a deleterious effect upon the kidneys of women suffering from nephritis, and that such women should not marry. There are two groups of cases in which the renal disease is directly attributable to pregnancy, those in which renal œdema is developed in the middle months and those terminating with œdema. In most cases albumin and tube casts disappear from the urine soon after the pregnancy has terminated. The writer ranges himself with those authorities who regard these kidney changes as pregnancy as essentially similar in kind to those which may occur

in scarlet fever, and holds that there is no intrinsic difference, but only one of degree and acuteness, between the renal changes in eclampsia cases, and those in cases where renal oedema is a prominent symptom less late in the pregnancy. Albuminuric retinitis is more common in pregnancy kidney cases than in other forms of nephritis. The deleterious effect of twin pregnancy upon the kidneys is more marked in the eclampsia cases than in those of general oedema without eclampsia. All statistics show a high mortality amongst the children of nephritic mothers. The treatment of an eclamptic case lies mainly with the obstetrician. The nephritis of the earlier months, however, calls for obstetric measures in but few cases. Rest in bed, with suitable medication and diet, ameliorates the renal symptoms in many cases. Pregnancy seems to be one of the causes of tetany, differing in no essential way from adult tetany due to other causes. The affection develops during the later months of pregnancy, as a rule, but the spasms are rarely met with during labor. They may occur for the first time during lactation. Pregnancy does not predispose to a primary attack of appendicitis, but may light up another attack in a person who has previously suffered from the disease. This last it probably does by stretching or breaking down old inflammatory adhesions as the uterus enlarges and rises out of the pelvis. It is not at present possible to state whether the coexistence of pregnancy makes an attack of appendicitis more severe than the average. Yet pregnancy does increase the risks and dangers; even after drainage of the abscess a septic salpingitis or endometritis may be set up. The fœtus is born dead in ninety per cent. of the cases. On the whole, operative measures should be accelerated rather than postponed in cases of appendicitis complicated by pregnancy. It is in the last degree undesirable that obstetric measures for terminating the pregnancy artificially should be resorted to, for fear of breaking down adhesions that are helping to localize the inflammation. Early operation is the best chance of saving both the mother and the child.

**3. Experimental Gastric Ulceration.**—Bolton, by injecting rabbits with an emulsion of the stomach cells of guinea pigs, has succeeded in preparing a gastrotoxic serum active against the gastric cells of the guinea pig. Injection of the serum into another rabbit produces no effect, but in half an hour after intraperitoneal injection of the serum into a guinea pig the symptoms of intoxication are well marked, and death occurs within twenty-four hours. The post mortem lesions are limited to the stomach and always occur within the first twenty-four hours after injection. If the animal survive, no further symptoms or lesions occur. This limitation of the lesions to the stomach does not indicate that the serum is specific in its action; other tissues are also affected, as is shown by the symptoms and death of the animal. The lesions consist of patches of necrosis in the mucous membrane, stained black by altered blood pigment. They are usually multiple and often nearly the whole mucous membrane is affected. After from twenty-four to forty-eight hours the black tissue has completely disappeared, leaving perfectly clean and sharply punched out

ulcers. The ulcers heal in from fourteen to twenty-eight days, but may perforate on the third or fourth day, causing death or a local abscess. The gastrotoxicine itself is unable to produce necrosis and ulceration of the mucous membrane of the stomach; these are brought about by the gastric juice. If this be put out of action by alkalies, etc., no lesion can be found. The serum is capable of bringing about two well defined reactions in the test tube—it is hæmolytic and contains several precipitins. From the above observations it seems possible that not only certain endogenous but also certain exogenous poisons may be capable of initiating self digestion, through the blood stream, and that the production of such lesions may be facilitated not only by hyperacidity of the gastric juice, but also by other bodies introduced with the food. It is possible that the chronicity and refusal to heal of the human gastric ulcer may depend on a secondary bacterial infection of the ulcer largely owing to muscular insufficiency.

**6. Precipitins in Hydatid Disease.**—Welsh and Chapman's conclusions are as follows: 1. The interaction between selected hydatid fluids and a sufficiency of the serum of a patient affected with hydatid disease has, in their experience of nine cases, never failed to give a positive precipitin reaction when tested before operation. 2. Not all hydatid fluids are capable of eliciting this reaction, and their failure is not associated with any noticeable diminution of their protein content. 3. Persistence of a marked reaction some weeks after operation probably indicates the continued presence of the parasite, but the disappearance of the reaction does not necessarily indicate complete removal of the cysts. 4. A positive reaction is independent of the site of the hydatid cyst (hepatic, peritoneal, muscular) and independent also of the nature of its contents (clear, turbid, or purulent).

2. Cholera in Constantinople. The Search for the Vibrio of Cholera in Molluscs and in Sea Water,  
By FERID IBRAHIM.
3. Mikulicz's Disease,  
By R. ROMME.

**1. The Antibody in Experimental Practice.**—Hallion devotes considerable space to the definition of such terms as antibody, amboceptor, etc., and tries to make his definitions clear by means of schematic diagrams. He deals with the different classes of antibodies, the sensibilizers or amboceptors, and the alexin or complement, and then passes to the

reciprocal reactions of these upon each other, which he presents in mathematical form as five propositions. He then presents problems to be solved by means of the antibody, the mode of procuring each of the substances mentioned, the effects produced by the combination of the alexin with the antibody, and the solution of problems in practice.

2. **Cholera in Constantinople.**—Search for the vibrio of cholera in molluscs and sea water. Ibrahim reports failure to find the cholera vibrio in the molluscs examined or in the sea water.

- Primary Carcinoma of the Vermiform Appendix, By S. ISAAC.
- Concerning the Disinfection Value of the New Kresol Soap of the Ministerial Decree of October 19, 1907, By E. SELIGMANN.
- Myoma of the Uterus in Young People, By L. LANDAU.
- Concerning Narcosis by Suggestion, By BENNO HALLAUER.
- Concerning the Treatment of Bartholinitis with Bier's Hyperæmia, By THEODOR PLASS.
- The Idiopathic Gangrene of the Skin in Infancy, By PAUL HEIM.
- The Theory of the Action of Sulphur, By DIESING.
- The Oxidation of Sugar, By GEORG ROSENFELD.
- Ætiology of Tuberculosis, By MAZYCK P. RAVENEL.
- Urine Gelatin with the Addition of Bile, By ROBERT GUETERBOCK.
- The Important Part Played by Near Work in the Origin of Myopia, By WALTER THORNER.
- Electrolysis in Cicatricial Stricture of the Esophagus, By A. W. ZUBERBÜHLER.
- Blood Conditions by the North Sea, By HÄBERLIN.

1. **Normal Histology of the Cortex of the Suprarenal Capsules.**—Störck says that a number of recent writers in the description of tumors of the cortex of the suprarenal capsules have mentioned glandular tubes within the parenchyma of the tumors, but declares as the result of his observations on the suprarenal capsules of both men and animals that a true glandular tube formation is never present, either physiologically or pathologically, in the cortex of the suprarenal capsule.

2. **Primary Carcinoma of the Appendix.**—Isaac gives a full account of the findings at autopsy on a man twenty-five years of age, whose appendix was found to have been totally destroyed by a carcinoma. The principal other pathological conditions noted were an extra-peritoneal paravascular abscess, multiple abscesses of the liver, an ichorous abscess in the right lower lobe of the lungs, multiple purulent pulmonary emboli, multiple infarcts and abscesses of the lungs, purulent thrombus of the vena cava inferior, endocarditis of the tricuspid valve, empyema of the pleura on each side, thrombo-embolism of the spleen, abscess of the brain and fatty degeneration of the heart and of the liver.

4. **Myoma of the Uterus in Young People.**—Landau states that among the last four hundred

cases operated on by him for myoma of the uterus there were forty-two women between the ages of twenty and thirty.

5. **Narcosis by Suggestion.**—Hallauer advocates the practice of narcosis by suggestion in cases where slight operations are to be performed or for the purpose of making examinations.

7. **Idiopathic Gangrene of the Skin in Infancy.**—Heim reports three cases of this nature met with in children three weeks, six months, and nine months old. In each there was a circumscribed gangrene of the skin of the leg which did not appear to be due to traumatism. Very few such cases are on record.

10. **Ætiology of Tuberculosis.**—Ravenel is of the opinion that the digestive tract is a very frequent place of entrance for the tubercle bacillus; that the tubercle bacillus is able to penetrate the uninjured mucous membrane of the digestive canal without leaving a trace of its entrance, and does this most readily during the digestion of fat; that the bacilli pass with the chyle through the lymph vessels and the thoracic duct into the blood, which carries them to the lungs, where they are in great part caught in the tissue; that infection by way of the intestine is particularly frequent in children; that the milk of tuberculous cows is in many cases the source of the infection (the exact proportion cannot yet be determined, but it is probably great); that tuberculosis can be carried by kissing, by touching with soiled hands, by injuries during autopsies, by cleansing of vessels used by consumptives, but these forms of infection play a comparatively slight part in the spread of the disease.

- Intestinal and Anorectal Infection, By LOB.
- Compilations from the Field of Experimental Psychology and Pathophysiology, By HENNING.

1. **Pneumonia Caused by Friedländer's Bacillus.**—Apfel states that of seventy-seven cases of pneumonia bacteriologically investigated during 1907 he found in sixty the *Francisella pneumoniae*, in ten the *Streptococcus pneumoniae*, and in seven the *Diphtheria bacillus*. But of these seven last were cases of mixed infection with the *Francisella* and one with the *col.*, so that among the entire seventy-seven cases there were only two which were of pure Friedländer infection. His conclusions

are that there are pneumonias which are caused by the *Diplobacillus capsulatus*, discovered by Friedlaender in 1883, as: 1, Proved by the presence of this bacillus in the blood and also in the sputum during life, and in one reported case in the secretion from an open wound in a patient with pneumonia and the same bacillus in the sputum; 2, indicated by the agreement between the clinical picture of the cases, absence of herpes and chill, with a severe course, the macroscopic and microscopic characteristics of the sputum, and the pathological preparations made from these pneumonias; 3, the diagnosis of a Friedlaender pneumonia can be made from the mucous sputum microscopically rich in capsulated bacilli; 4, in regard to the prognosis, which is apt to be very bad, it is well to be guided by the result of the bacteriological examination of the blood; 5, treatment does not differ from that of the pneumonia due to the lanceolatus.

2. **Serum Treatment of Streptococcus Infections.**—Zangemeister asserts that his experiments show that the antistreptococcus sera obtained to-day from the horse are totally ineffective on monkeys, which renders it very probable that they are equally so for men; that monkeys can be passively immunized against streptococci, the same as other animals, as long as the serum of one of their own kind of animals is used; that antistreptococcus sera, so far as they cannot be tested directly on men, should be tried on monkeys; that, aside from the fact that horse immune serum is worthless, it may be directly injurious to monkeys, and cause the death of the animal experimented upon.

3. **Karell's Treatment.**—Jacob reports a number of cases of serious cardiac disease which he has treated with excellent results along the lines laid down in 1868 by a Russian physician named Karell, the patient to drink 200 c.c. of milk four times a day, the milk to be raw or scalded according to taste and at such a temperature as may be agreeable. Aside from this, the patients get neither solid nor liquid food during the first five or seven days, after that other food is gradually added; at first, one egg about 10 o'clock, and some zwieback about 6 o'clock, then two eggs, some black or white bread, then other additions are made until, some twelve days after the commencement of the treatment, the patient has returned to full mixed diet.

7. **Treatment of Gonorrhoea with Arhovin.**—Knauth speaks very highly of the internal administration of arhovin as a remedy for gonorrhoea in both the acute and chronic stages. In taking the place of the method of treatment by injections, it avoids the dangers of the latter, such as injuries of the urethra, and carrying the gonorrhoeal poison into the posterior part of the urethra with its undesirable consequences of provoking inflammation of the bladder or of the epididymis. During the past year he has thus treated eleven patients with acute, eleven patients with subacute or chronic gonorrhoea, and seven patients with epididymitis, giving from four to six capsules containing 0.25 gramme of arhovin by the mouth. In the most acute stage the diet is restricted mainly to milk, the patient is kept in bed, and ice applied locally. When the discharge assumes a more watery, mucous character the patient is allowed up and given his usual diet without alcoholic beverages.

10. Erysipiloid of Rosenbach. A Note on Its Occurrence in Laboratory Workers, By J. H. JORSON.
11. The Symptom Complex of Transverse Lesion of the Spinal Cord and Its Relation to Structural Changes, By A. R. ALLEN.

## 2. The Epidemiology of Acute Poliomyelitis.

—Holt and Bartlett draw the following conclusions: The occurrence of epidemics and the relation of certain groups of cases to one another in these epidemics place beyond question the statement that acute poliomyelitis is an infectious disease. Whether we can go farther and state that the disease is communicable is an open question. After carefully considering all the evidence brought together in this paper the authors cannot resist the conclusion that the disease is communicable, although only to a slight degree, one of the most striking facts being the development of the second cases within ten days after possible exposure. Positive statements must be deferred until the discovery of the infectious agent. A table is given collating the principal facts regarding the epidemics, together with the references to the literature.

3. **Suppurative Phlegmonous Gastritis.**—Bovée thinks it is evident that until the report of his case no case of phlegmonous gastritis had been operated on. In four cases, which are cited, there is a very strong relation to the suppurative form of the disease. It would seem, and particularly from these four cases, that opportunity for drainage by abdominal section and external drainage, with or without gastric incision, is necessary. Gastrostomy or gastroenterostomy seems to be strongly indicated, particularly as the pyloric end of the stomach is usually most involved. In the author's case the pylorus was completely obstructed. Gastroenterostomy would afford drainage of the stomach into the intestine, and incision into the submucous coat, with adequate technique, would afford exit for pus and relieve tension. Robson and Moynihan recommend in moderate terms gastrostomy or gastroenterostomy in acute phlegmonous gastritis, and in the circumscribed form they remark that opening and drainage of the abscess would be advisable.

4. **Gallop Rhythm of the Heart.**—Robinson believes this is a clinical phenomenon of considerable frequency and consists of three cardiac tones, none of them being murmurs, occurring under variable clinical conditions. The form which is heard

over the apex or the central part of the præcordium may be divided into presystolic, protodiastolic, and mesodiastolic types, as the extra tone falls at the end, beginning, or middle of the diastole. Each form is associated with a characteristic cardiogram and is produced by a combination of factors. The presystolic form may be heard in strongly acting hearts, the tone being caused by an hypertrophied auricle, and also in weak, rapid hearts at the height of acute febrile diseases, the extra tone being produced in the auricle rather than in the ventricle. The protodiastolic and mesodiastolic forms are caused by the production of an extra tone in the ventricles, the factors being an increase in the amount and velocity of the blood flow from the auricles to the empty ventricles, and a loss of tone of the heart muscle of the ventricles. The longer silent period with gallop rhythm is usually systolic.

**5. Toxæmia from the Standpoint of Perverted Metabolism.**—Webster defines toxæmia as a condition characterized by the overloading of the blood with normal or abnormal products of food or tissue metabolism. It is purely endogenous and distinct from toxæmia due to exogenous products or from toxæmic states arising in the course of infectious disease. Abnormal activity of any organ may result in the overloading of the blood with products which lead to various toxæmic symptoms or may so influence the activity of other organs that abnormal results will follow. Such may be the influence of the thyroid, the ovary, the testicle, the pancreas, the suprarenal, and the hypophysis on the general functions of the body. The author then discusses in succession intestinal, hepatic, renal, and thyroid toxæmias, and concludes that toxæmia, apart from that which follows acute or chronic bacterial processes, is always of metabolic origin. The toxæmias discussed are more the effects of a general metabolic perversion than of a direct organic disorder.

**6. The Relaxed Knee Joint.**—Freiberg summarizes his paper in the following propositions: 1. Many cases of so called functional knee symptoms are due to reflex atrophy of the quadriceps extensor muscle resulting from injury. 2. The term relaxed knee joint should be reserved for such cases. 3. The injury may be so slight that its ætiological relation may be overlooked. 4. The atrophy following in many cases cannot be explained as a consequence of inactivity. 5. A cure in this condition will be accomplished only when the quadriceps extensor muscle is restored to its normal volume and strength. 6. Recovery is so protracted in some of the cases as to suggest serious injury to the central nervous system. 7. Though the treatment of the prolonged cases is necessarily limited to the periphery, they will ultimately recover with persevering and well directed efforts.

**1. A Case of Meningeal Tumor Compressing the Cerebellum.**—Baldwin reports a case of slowly growing brain tumor. The first symptom of the disease appeared ten years before death. The tumor grew to such a size that it would seem that it must have given characteristic symptoms, yet optic neuritis never developed, there were only a few attacks of vomiting throughout the illness, and these were evidently due to acute indigestion, and, while headaches occurred for short periods daily in the early years of the disease, during the three years before the patient's death they did not recur. During the course of the illness the symptoms so closely simulated those of Parkinson's disease, of arteriosclerosis of the vessels in the cerebrum and cerebellum, and of cyst of the cerebellum, that, while the question of brain tumor was always considered, the symptoms at no time seemed to justify an exploratory operation. In reviewing the history of this case, says the author, it will be seen that, while the symptoms of brain tumor were not distinctive, those due to cerebellar involvement were marked throughout the course of the disease. These include the attacks of suboccipital headaches, the cerebellar ataxia, the cerebellar seizures—sudden relaxation and falling with no vertigo or unconsciousness—and the tendency when sitting to drop the head toward the left shoulder. The symptoms of involvement of cranial nerves also pointed to a localization of the disease at the base of the brain—the nerve deafness in the right ear, dysphagia, and anæsthesia of the tongue. But, while the involvement of the cerebellum was evident, the lesion seemed to be one of degeneration rather than of compression from an extracerebellar growth.

**2. Melancholia with Delusions of Negation: Three Cases with Autopsy.**—Mitchell and Southard describe the history of three such cases, the anatomical side of which present several common aspects, but little which promises to explain the disease. Arteriosclerosis, when confined to the large branches of the circle of Willis, can scarcely be invoked as underlying symptoms of such specialized character as those under consideration. Just as the patients showed strikingly little in alterations of reflexes, so the brains showed strikingly little in the shape of gross or focal alterations. Moreover, the brains gave little evidence of general or focal atrophy. No striking alterations in cortical topography and arrangement of layers could be detected on microscopical examination. Pigment bearing cells in perivascular spaces were constantly found; and, in default of any suspicious localization of these, they should be attributed rather to the results of advancing years than to a special factor. Neuroglia cell pigmentation was also quite constantly found; but this was not so universal in distribution as was the case with the perivascular cell pigmentation. Common to all three cases was a neuroglia cell pigmentation in the intermediate areas of the areas of cortex examined. The relation of the neuroglia cell pigmentation to cortical activity could not be made out. Satellite cell pigmentation was not constant. Nerve cell pigmentation was constantly found in the elements of moderate size in all parts of the cortex examined. This pigmentation was strikingly brought out by the use of iron hematoxylin.

## Proceedings of Societies.

### MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK.

Meeting of February 17, 1908.

The President, Dr. THOMAS E. SATTERTHWAITE, in the  
Chair.

(Concluded from page 910.)

**Metaplasia of the Appendix Vermiformis and a New Diagnostic Point.**—This was the title of the address made by the president-elect, Dr. ROBERT T. MORRIS. The time had now come, he said, to classify appendicitis cases under four separate and distinct kinds: 1, Normal involution, beginning with a metaplasia of the lymphoid and submucous coat and ending with connective tissue replacement of all coats. During a part of the involution process the patient suffered from local and reflex disturbances, and this class of cases included probably the larger proportion of all patients affected with disease of the appendix. Although this was by far the most common variety of appendicitis, it was the one most seldom recognized. 2, Infective appendicitis, the form most often recognized. 3, Congestive appendicitis, accompanying, for instance, ascites or pressure from a floating kidney. 4, Appendicitis secondary to some external affection, like cancer or tuberculosis, of slow development. If it was asked, Do these four types merge one into another? he would answer, Not often, in his opinion. Much confusion had existed in his own mind in regard to this subject until recently, but now he believed that some, at least, of the perplexities with which it was attended had been cleared away. The reason why we did not have normal involution merging into infective appendicitis was because, as a result of the involution, there was a disappearance of those elements in the appendix which were most necessary to an infectious process. The third and fourth types, in consequence of the slow character of the swelling, seemed to call out the elements of protection against infection. It was his belief that the chief cause for the disasters in appendicitis was to be found in rapid swelling. The tension produced by this gave rise to compression anæmia, and in this way the tissues were rendered vulnerable to bacterial invasion.

In normal involution the metaplasia might go on for years. The patient very rarely had to take to his bed. In exceptional instances, however, the occurrence of spasm of the intestine at times might necessitate this. But such patients suffered not a little from intestinal dyspepsia, and it was undoubtedly true that metaplasia of the appendix occasioned more intestinal dyspepsia than any other one cause. Defective metabolism was a result, and the patients suffered from a long train of secondary effects, including, in many instances, various local neuralgias due to irritation of nerve filaments entrapped in the new connective tissue. This form of appendicitis was not likely to explode; the chief mischief resulting from it was the discomfort and nagging described, lasting for years. In it, therefore, it was not necessary to remove the appendix, on account of existing or threatened danger, but re-

moval was often highly desirable for the comfort of the patient. Dr. Morris here presented three specimens showing the process of involution in different stages. In the third and most advanced specimen there was nothing left but peritonæum. It was worthy of note, he said, that throughout the process, however, the nerve fibres remained.

As an aid to the diagnosis, he had found a certain point of value. This was in the course of the line drawn from the right anterior spinous process of the ilium to the umbilicus, upon which McBurney's point was located; but, while the latter was an inch and a half from the spinous process, the new point was situated an inch and a half from the umbilicus. This point had reference to tenderness, elicited by finger pressure, of the right lumbar ganglia of the sympathetic system, and in cases of normal involution of the appendix there was persistent tenderness at the point. In irritations of pelvic origin, both right and left lumbar ganglia were tender. In making differential diagnoses, therefore, this was a point of great value. For instance, if, in a case in which the appendix and the right Falloppian tube were bound together by adhesions, we wished to decide whether certain symptoms proceeded from the appendix or from the oviduct, the point described would alone be tender if the symptoms came from the appendix, while, if they came from the tube, both right and left lumbar ganglia would be tender.

Dr. ROBERT F. WEIR said that Dr. Morris had originated many new ideas, and, while he was not invariably right, it had often proved the case that the surgeons had come to adopt them. He could not see how the process described prohibited infectious invasion. The smaller the lumen of the appendix, the less chance there would be of such invasion, but unless there was complete obliteration, it seemed to him that there was always the possibility of this taking place. Nor could he see exactly how the line between the two forms of appendicitis could be drawn so finely as the speaker would have us believe. If, however, the experience of other observers confirmed the position taken, it would certainly be a great point gained. It would be on a par with the achievement of McBurney in appendicitis. While many surgeons were now disposed to attach less significance to McBurney's point than formerly, he personally still regarded it as of the greatest significance, provided proper methods are employed in the examination. His own experience with finger point pressure in the location indicated by Dr. Morris had been very limited, but in two cases of the character described, which he had recently examined, there had been no pain elicited at this point. Since this new proposition had been brought to his attention he had made a study of the anatomical relations of the parts involved, and from this it appeared to him that the pain would naturally emanate from the lower dorsal, rather than the lumbar, ganglia. It had then occurred to him that the condition might possibly be due to an infection by means of the lymphatics. Perhaps a larger experience would bring all observers into full accord as to the points at issue.

Dr. ALGERNON T. BRISTOW, of Brooklyn, said that the normal involution of an organ was not measured by the life of any man. It was a matter

of a very long period, even thousands of years. As illustrating this, he referred to the development of the intestinal canal in successive generations of animals, requiring many centuries for its completion. He strongly objected to having chronic appendicitis designated as a normal involution. It was no more this than cirrhosis of the kidney was a normal involution. In the latter there was a strangulation of the glandular structure of the organ, and the process in the appendix was entirely analogous. The relatively poor blood supply of the appendix was one of the factors which favored inflammation; another was the poor drainage of the organ. If, now, infective material was added, we had the triad which was necessary for the production of appendicitis. Although the first two of these were constantly present, without the addition of the third factor, infection, there could be no appendicitis. With the exception of the use of terms, the speaker said that he was, in the main, in accord with Dr. Morris, though he would go further than the latter in regard to some points. The condition in the cases described was not one simply of discomfort, but amounted to really one of chronic ill health. He would not say that this kind of cases never exploded, for he had found that they did occasionally explode. As a rule, however, the operations in such cases were not life saving operations, like those in acute appendicitis. The happiest results generally followed the operation, so that patients who before were suffering a miserable existence were completely restored to health.

Dr. ALEXANDER B. JOHNSON said that only a few years ago a surgeon would have been laughed at if he maintained that an inch and a half for the incision and a week and a half's confinement were all that were required for an appendectomy. Yet in interval operations these were now quite sufficient. He thought that we should not form too hasty opinions in regard to Dr. Morris's contentions. The matter should be thoroughly sifted by surgeons generally, and he for one would be glad to give the new diagnostic sign a thorough practical test. The term normal involution seemed to him a proper one. Evolution and involution went on in the individual, just as they did in the race. It was possible to have an appendix which in one part was undergoing involution, while another part was the seat of infection. In exceptional instances, he had also seen rupture in cases of tuberculosis of the appendix, and even of cancer. In the class of cases described by Dr. Morris it was advisable to operate when the symptoms became sufficiently troublesome, and in a fairly large proportion of such cases, in his experience, the appendix appeared to be undergoing normal involution. He was much interested in the question of whether it was possible in certain instances to distinguish between disease in the appendix and in the right Falloppian tube, and if the Morris sign enabled us to determine this point it would prove exceedingly useful.

Dr. EUGENE LORINC said that for a number of years he had observed that a tender point was apt to be found in the location indicated by Dr. Morris. He could not, however, subscribe to the opinion that it was present only in normal involution, as he had certainly met with it in ordinary cases of appendicitis. It would not do to be too exact in placing the

position of the point of tenderness, since it might be a little more or a little less than an inch and a half from the umbilicus. The distance between the latter and the anterior superior spinous process of the ilium was usually set down as seven or eight inches, but he had repeatedly seen instances in which this line measured only four inches. In such cases the McBurney point and the Morris point would be very close together, and it was conceivable, with the variations in the seat of tenderness which must be taken into consideration, that the two points might even be identical. On the whole, it seemed that the exact point might be a little difficult to find. In one young lady whose ovaries and tubes were normal he had elicited pain on pressure at Morris's point, and yet this could not have been due to appendicitis, because he had removed the appendix four years before.

Dr. JOHN B. WALKER said that, like Dr. Johnson, he had seen a number of cases in which a large part of the appendix had become obliterated, and yet in which abscess was associated with the condition.

Dr. CHARLES H. PECK said that several times he had been much puzzled in trying to distinguish between disease of the appendix and of the right Falloppian tube, and he argued with Dr. Johnson that, if the Morris sign could be well established, it would prove of special value in such cases. He had found it difficult also to distinguish between obliterative appendicitis and the milder attacks of inflammatory appendicitis, and thought it very desirable that the distinction between the two should be more clearly defined.

Dr. ALBERT A. BERG said that at times the meaning of pain located in the lower right quadrant of the abdomen was very difficult to determine. If the appendix alone was in this situation there would be no trouble about the matter; but there were also many other structures here which might be the seat of disease, the recognition of which was most important. It was the experience of all hospital surgeons that without any inflammation of the appendix whatever there might be localized pain in this quadrant. Thus, it might be due to stone in the right ureter or other abnormal condition in the ureter, or to a colitis. To make a diagnosis only on pain seemed to him a step backward. Still, in the way of corroborative evidence, the Morris sign, if substantiated, would be of great assistance. As to the liability to explosion in appendices which were somewhat obliterated, he thought there was little danger of this if the normal involution was taking place regularly. In some instances, however, stricture formation was met with, and in these he believed there was greater liability to infection (in consequence of the presence of stricture) than in the normal appendix in which no involution had occurred.

Dr. MORRIS said that he had devoted much careful study to the subject before making known the conclusions at which he had arrived, and he was much pleased to have had such a full and intelligent discussion of the points at issue. He would endeavor to reply to the various criticisms and inquiries in turn. In cases where we had intercurrent appendicitis and also the presence of hyperplastic connective tissue, we had a history of active attacks

of acute appendicitis. Wherever we had scar tissue from previous infective appendicitis, such attacks were apt to be met with; but in such cases we did not meet with the persistent discomfort and repeated attacks of a few hours' duration which were characteristic of normal involution. As to Dr. Weir's anatomical studies, the lymphatic connection between the appendix and the lumbar ganglia was not direct, and the condition was not one secondary to an infection carried by the lymphatics. Dr. Bristow thought the nomenclature wrong. He (Dr. Morris) had found much difficulty in getting a proper nomenclature, and he was by no means satisfied with the results thus far attained in this direction. For want of a better term, he had suggested "metaplasia." He believed that in rare instances we did have inflammatory processes associated with normal involution, but such an occurrence was accidental, rather than a natural sequence. He entirely agreed with Dr. Bristow as to the happy results usually following an operation. We not infrequently heard of appendices which, after being taken out, were found to be normal. While they might appear to be normal, he did not believe they were so, for if they are examined microscopically it would be seen that they were in process of involution. Dr. Johnson was correct in asserting that perforation might occur in tuberculous or cancerous cases, but when this was the case it was not an acute phenomenon. The matter of the oviduct and the appendix was one which he had worked out very carefully. In reply to Dr. Torek, he would say that the measurement of an inch and a half was not meant to be absolute; this distance was rather a bull's eye at which to aim, and which it would be well to keep in mind. As to the existence of pain at the inch and a half point in the case in which the appendix had been removed, he believed that this was due to the presence of adhesions at the site of the removed appendix. Coming to the remarks of Dr. Berg, Dr. Morris said that he himself had seen a number of instances of inflamed ureter which might possibly have been mistaken for appendicitis, but in making the diagnosis of these he had depended rather on the collateral symptoms and the clinical history. The localized point of tenderness which he had described was a sign characteristic of normal involution, but not peculiar to it. He would never think of operating unless the corroborative evidence afforded by palpation was present. As to the stricture formation referred to, even here he had felt that potetion from infection was called out by the leucocytosis developed.

### Letters to the Editors.

#### THE WORD "PALLIATIVE."

53 EAST FIFTY-EIGHTH STREET,  
NEW YORK, May 11, 1908.

#### To the Editors:

I have read the criticism by Dr. A. Rose of my use of the term "palliative" in the title of my paper, which was published in the *Journal* of April 18th, and have noted the fact that Dr. Rose asserts that my interpretation of this term was erroneous. Had

this criticism been made by one less scholarly than Dr. Rose, I should have felt impelled to ignore it; under the circumstances, however, I feel compelled to answer.

My justification for the use of the word "palliative," in the sense in which I employed it, rests upon authority which is good enough for me. If the doctor will turn to Foster's *Medical Dictionary* he will find the adjective palliative upon page 2508, as follows: "Palliative, adj. Lat., palliatus. Fr., palliatif. Ger., lindernd (adj.). Palliativ (n.). Tending to moderate a morbid condition without curing it; as a n., a p. agent." If the doctor will carefully read the article in question, he will find that its entire sense is exactly in the spirit of this definition, i. e., the moderating of a morbid condition without curing it. Nowhere in the article is there any claim made to curing prostatic hypertrophy by these measures, but simply the amelioration of the symptoms dependent upon or resulting from the disease of the gland. In view of the measures advocated, I should not have been justified in using the term "nonoperative," since I have frequently referred to the use of the catheter and cystoscope, which, in the eyes of surgeons, is an operative procedure.

Dr. Rose, in his communication, states: "Palliative, from Latin palliatus, a, um, means covered with a cloak; in medicine palliativum, or palliative remedy or treatment, is a remedy or treatment which is employed to ameliorate symptoms, to do for a while, until a radical remedy (not necessarily operative) can be applied or in case a radical cure is out of the question." The entire article is in the sense of the doctor's definition of the term "palliative," as quoted above, which must become clear at once to any one carefully reading it.

In view of these facts—that is, my justification for the use of the term in the sense in which it was employed, first by Foster's *Dictionary* and, secondly, by the definition given by Dr. Rose himself—I must insist that my use of the word was correct.

F. BIERHOFF.

#### ABOUT DR. PALIER'S ARTICLE ON PYLORIC INSUFFICIENCY.

616 MADISON AVENUE,  
NEW YORK, May 13, 1908.

#### To the Editors:

Glancing over the table of contents of the last issue, for May 16th, I noticed the heading of Dr. E. Palier's article, A Case of Chronic Diarrhœa Accompanied by Pyloric Insufficiency. I confess that I felt quite pleasantly over the fact of having gained another convert to my teachings. At least I thought so after glancing over the title. In looking over the article I read with delight the history of the case and the method by which Dr. Palier made the diagnosis. Very properly does Dr. Palier deny the possibility of dealing with hypermotility of the stomach, instead of with insufficiency of the pylorus. Very properly also does Dr. Palier assert that the passage of undigested food probably acted as an irritant on the intestines. But how painful did I feel when at the end of his article I saw no mention of my name at all! Had

Dr. Palier abstained entirely from quoting any one—well, it would have been different. But he did mention Seré and Ebstein, whom (the latter one only) I also mentioned in my first monograph. In this article, *Insufficiencia Pylori, a Sequela of Chronic Gastritis, with Reports of Fourteen Cases Successfully Treated* (*Philadelphia Medical Journal*, May 24, 1902), he will find, right after my quoting an abstract from Ebstein, one sentence reads thus: "Why must hypertony of the stomach be accepted to explain the absence of food in the stomach at too early a time?" In this article, as in the subsequent ones, the symptom, diarrhoea, is mentioned quite prominently, besides explaining its cause and effectual treatment. If Dr. Palier wishes to consult my works on this subject, I will give him here a partial list of additional publications in which he can read of insufficiency of the pylorus:

Further Remarks on Insufficiencia Pylori, *New York Medical Journal*, October 4, 1902; *Journal of the American Medical Association*, April 16, 1904; *Medical Record*, April 30, 1904; *Transactions of the Medical Society of the State of New York*, 1904; A Few Remarks on the Prospect of the Chronic Dyspeptic, *New Albany Medical Herald*, January, 1906; The Outlook for the Chronic Dyspeptic, *American Medicine*, March 10, 1906. I have referred to and made short mention of this very frequent disease in many other articles, but I think these will suffice for reference. I wish to bring out here these facts: That insufficiency of the pylorus, not a very occasional and nervous phenomenon, but as the usual and natural sequel of chronic pyloritis, was first described by me in May, 1902; that insufficiency of the pylorus is a very frequent condition—I have seen, treated, and cured dozens of cases; that insufficiency of the pylorus is the true condition, and not achylia gastrica, so mistakenly, as I believe, taught by Einhorn; that the method of diagnosing it is the repeated giving of test meals and aspirating them at intervals of less than one hour after the Ewald's test breakfast; that one of the symptoms of insufficiency is chronic diarrhoea, which can be checked in from two to three days, and absolutely cured in about as many weeks. I have reported the cure of chronic diarrhoeas which had persisted for from five to nine years. Boardman Reed, in his book, *Diseases of the Stomach and Intestines* (1904), has this to say on page 868: "When pyloric incontinence exists, in the absence of any mechanical cause for it, the more plausible explanation seems to be the one championed by Knapp," and on the following page he says: "Knapp insists that insufficiency of the pylorus is quite frequent, and that it is the natural result of a prolonged condition of hypertonicity of the part, the overtaxed muscle finally becoming exhausted and weak. He maintains that a too rapid emptying of the stomach is evidence rather of an exhausted and relaxed pylorus than of hypermotility of the gastric walls, . . . and it would follow further that . . . diarrhoea may be produced . . . by pyloric incontinence."

It is rather strange, although perfectly possible, that Dr. Palier came to the same results and followed the same channels of reasoning apparently as I did six years ago, without knowing anything of my many contributions on this highly interesting subject which have appeared since my first article. But the fact is that I have been teaching the existence of that disease and the method of diagnosing and curing it for the last six years, besides taking part in discussions in societies. Knowing Dr. Palier quite well, I am sure that this letter will cause him to hunt up the literature and that at his earliest opportunity he will hasten to rectify the omission after convincing himself of the truth of the purport of this letter. I am glad, however, that there is another believer in insufficiency of the pylorus, and that possibly in the near future we may be able to demonstrate by concerted action the utter fallibility and the inherent fallacy of Einhorn's teaching about "achylia gastrica." Let me pray, for the betterment of mankind, that we may soon succeed in unmasking that diabolical disease "achylia gastrica," even if we have to throw overboard all of the cherished teachings of Einhorn.

MARK I. KNAPP.

### Book Notices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

*Thomographia Dermatologica*. . . . . Tabulae selectae . . . . . editae a ALBERT NEISSER, Breslau, Eduard Jacobi, Freiburg i. Br. Fasc. iii. Berlin and Vienna: Urban & Schwarzenberg; Paris: Masson & Cie; New York: Rebman Company; London: Rebman Limited. Pp. (text) 79 to 125; plates 20 to 32.

This fasciculus of Neisser and Jacobi's *Atlas of New and Rare Skin Diseases* (one of the subtitles of the work) quite maintains the degree of excellence shown in the preceding fasciculi in both text and illustrations. The atlas as a whole cannot fail to be exceedingly useful to the general practitioner as well as to the specialist in dermatology.

*The Functional Inertia of Living Matter. A Contribution to the Physiological Theory of Life.* By DAVID FRASER HARRIS, M. B., M. D., B. Sc., F. R. S. E., Lecturer on Physiology and Normal Histology in the University of St. Andrews, etc. London: J. & A. Churchill, 1908. (Through P. Blakiston's Son & Co., Philadelphia.) Pp. 136. (Price, \$2.)

Two hundred and thirty years ago Francis Glisson, M. D., of Cambridge, gave to the science of his day the conception of the irritability of living matter. The astonishing growth of biology witnessed since that time is due in an exceptional degree to the potentiality for advancement conferred by the recognition of this property of affectibility in living matter. But the ultimate processes underlying what is called life can scarcely be conceived of as wholly made up of irritability, or affectibility, as some prefer to call it. To rest here would be tantamount to an admission that life is but uninterrupted response, ceaseless activity, endless unrest. This is contrary to what we know of the capacity and physiological wants of the human organism or, indeed, of any organism. Nowhere among living things is affectibility, continuous, unrestricted, and unimpeded, to be met with. Consequently, if we would conform theory to the exactness of biological fact, we are obliged to ascribe a further quality to protoplasm, that of insensibility. As Dr. Harris observes, the results of the

possession of this second attribute have been, to a certain extent, appreciated by philosophical biologists; but, so far as he is aware, no one has till now "formally asserted that livingness consists in the simultaneous possession by protoplasm of two physiologically opposed properties—*affectibility* and *insusceptibility*—or, as I prefer to call the latter, *functional inertia*."

These, then, are the essential or fundamental properties of protoplasm as Dr. Harris conceives of them. From his point of view, however, irritability (*affectibility*) is not of the same order as movement, secretion, etc. On the contrary, it is more fundamental—"a property of living matter, in fact, while the other things are *results of its existence*." Of "functional inertia" he observes that it is that "property of protoplasm whereby the living matter contrives to remain in a functional *status quo ante*, notwithstanding that it has received a stimulus, or, having responded to the stimulus, it continues to exhibit its functional activity for a certain time after the stimulus as a form of energy has ceased to exist."

Assimilation, certain aspects of metabolism, movement, secretion, and reproduction the author would regard as vital manifestations or results of *affectibility*; while from functional inertia he would derive automatic molecular changes and certain other aspects of metabolism, e. g., reproduction and rhythmic movements. As to the physiological significance of functional inertia, Harris is inclined to believe that, in many cases, it is destined to preserve the protoplasm from excessive activity (pages 126-127).

Finally, while the *results* of the possession by protoplasm of such a property as functional inertia had been perceived with clarity more or less by Hobbes and Faraday, and in our own day by Adams, Cattell, Guyau, Mercier, Mosso, Robertson, Woller, Ribot, Sharkey, Sherrington, Strotton, and Schaeffer—while even the term inertia was used by some or all of them—Harris found that, to adequately explain certain phenomena, he was obliged to ascribe to protoplasm a certain real or *positive property*, functional inertia, mere diminution or absence of *affectibility* being inadequate rationally to account for the occurrences. Functional inertia, in this sense, Harris attributes to the biogens, or living molecular constituents of protoplasm.

This, if we have read him aright, is a brief but true statement of the author's position with regard to one of the most complex questions in the whole range of biological science—a question which he has treated at every point with lucidity and logical acumen. Our author, in truth, is not one of those wizard prophets of Lilliput, who, mounting upon a stilt scaffolding of many syllables, would win to a fictitious altitude in the world of thought. His is no mumbojumbo of contorted eloquence. Rarely, indeed, have we met, in a work at once so abstruse and highly technical, with such a store of simple, sturdy English. It is hard to predict, perhaps we never can predict, the ultimate fate of such a biological subtlety as that which constitutes the burden of this writing. Only a churlish captiousness, however, could withhold commendation, in view of an argument so obviously sincere, of an imagination

working as far as may be under the guidance of experiment; of a judgment buttressed always by a strict observance of the laws of inference—a judgment finding, moreover, in elegance and simplicity its most congenial and convincing utterance.

*Immune Sera.* A Concise Exposition of our Present Knowledge concerning the Constitution and Mode of Action of Antitoxines, Agglutinins, Hæmolysins, Bacteriolysins, Precipitins, Cytotoxines, and Oponins. By Dr. CHARLES FREDERICK BOLDUAN, Bacteriologist, Research Laboratory, Department of Health, City of New York. Second Edition, Rewritten, First Thousand. New York: John Wiley & Sons; London: Chapman & Hall, Limited, 1907. Pp. viii-154. (Price, \$1.50.)

The cordial reception given immediately by the profession to the first edition of this book of Dr. Bolduan's is to be ascribed in great measure, we think, to his happy faculty of treating of difficult matters in language readily understood by the reader. The same felicity of expression will be found in the material added in the second edition, including short accounts of snake venoms and their antisera, agglutinins, opsonins, and serum sickness. The practical character of the book is well shown in the following passage from the chapter on opsonins (page 134): "There is little doubt that the opsonic indices do measure a certain fraction or phase of the immunity reaction; we do not believe that they replace clinical observations in measuring the effect of immunizing injections." We have nothing but commendation for this handsome little book.

*La Lutte contre les microbes.* Cancer, tuberculose, maladie du sommeil, tétanos, entérite et microbes intestinaux, variole et vaccine: L'Œuvre de Jenner. Par Dr. ETIENNE BURNET, de l'Institut Pasteur, chef du service de la vaccination de la Ville de Paris. Paris: Armand Colin, 1908. Pp. 318.

We have here an entertaining volume by an assistant and disciple of Metchnikoff, who discusses in a popular and discursive fashion numerous problems relating to various infectious diseases, including cancer, tuberculous disease, African sleeping sickness, tetanus, and intestinal putrefaction. There is also an historical retrospect and study of vaccination and the work of Jenner. The use of uncooked fruits and vegetables, especially those growing near the ground, is condemned as a probable source of many cases of obscure infection. Cultures of the Bulgarian lactic acid bacillus are recommended as an efficient means of combating pathogenic microorganisms in the intestine. In his essay on cancer the author commits himself more fully to the parasitic theory than, in our opinion, is justifiable in the present state of our knowledge.

#### BOOKS, PAMPHLETS, ETC., RECEIVED

The Opsonic Method of Treatment. A Short Compendium for General Practitioners, Students, and Others. By R. W. Allen, M. B., B. S. (London), Pathologist to the Royal Eye Hospital, London, S. E., etc. Philadelphia: P. Blakiston's Son & Co., 1908. Pp. 138. (Price, \$1.50.)

The Development of Ophthalmology in America. 1800 to 1870. A Contribution to Ophthalmological History and Biography. An address delivered in Abstract before the Section in Ophthalmology of the American Medical Association, June 4, 1907. Revised and Enlarged. Illustrated by Selected Portraits and Cuts. By Alvin A. Hubbell, M. D., Ph. D., Professor of Clinical Ophthalmology in the University of Buffalo, etc. Chicago: W. T. Keener & Co., 1908. Pp. 107. (Price, \$1.75.)

An Index of Treatment. By Various Writers. Edited by Robert Hutchison, M. D., F. R. C. P., Physician to the

London Hospital, etc., and H. Stansfield Collier, F.R.C.S., Surgeon to St. Mary's Hospital, etc. Revised to Conform with American Usage by Warren Coleman, M. D., Professor of Clinical Medicine and Instructor in Therapeutics in Cornell University Medical College, etc. New York: William Wood & Co., 1908. Pp. 888.

A Textbook of the Practice of Medicine. For Students and Practitioners. By James Magoffin French, A. M., M. D., Formerly Lecturer on the Theory and Practice of Medicine, Medical College of Ohio. Third, Revised Edition. Illustrated by One Hundred and Ten Engravings in the Text and Twenty-five Full Page Plates in Tints and Colors. New York: William Wood & Co., 1907. Pp. xxii-1253.

Abdominal Tuberculosis. By A. Ernest Maylard, M. B., B. S. (Lond.), Surgeon to the Victoria Infirmary, Glasgow, etc. Philadelphia: P. Blakiston's Son & Co., 1908. Pp. xvi-360. (Price, \$4.)

The Principles and Practice of Hydrotherapy. A Guide to the Application of Water in Disease. For Students and Practitioners of Medicine. By Simon Baruch, M. D., Professor of Hydrotherapy in Columbia University (College of Physicians and Surgeons), New York, etc. Third Edition, Revised and Enlarged. With Numerous Illustrations. New York: William Wood & Co., 1908. Pp. 544.

Cancer. Relief of Pain and Possible Cure. By Skene Keith, M. B., F. R. C. S. (Ed.), Author of *Introduction to the Treatment of Disease by Galvanism*, etc., and George F. Keith, M. B., C. M., Author of *Textbook of Abdominal Surgery* with Mr. Skene Keith. London: Adam and Charles Black, 1908. Pp. 155.

Scientific Nutrition Simplified. A Condensed Statement and Explanation for Everybody of the Discoveries of Chittenden, Fletcher, and Others. By Goodwin Brown, A. M. New York: Frederick A. Stokes Company, 1908. Pp. 200.

Taschenbuch der Physiologie. Von Prof. Dr. med. H. Bornatun in Berlin. Heft 1 und Heft 2. Leipzig: Dr. Werner Klinkhardt, 1908. Pp. 243.

La Diathèse urique. Par Henri Labbé, chef de laboratoire à la Faculté de médecine de Paris. Paris: J. B. Baillière et Fils, 1908. Pp. 95.

Lehrbuch der Ohrenheilkunde. Für Studierende und Aerzte. Von Dr. Georg Boenninghaus, Priv. Doz. für Ohrenheilkunde, Ohrenarzt am St. Georgs-Krankenhaus zu Breslau. Mit 139 Textabbildungen und 1 Tafel farbiger Trommelfelbilder. Berlin: S. Karger, 1908. Pp. viii-376. (Price, M. 9.80.)

Beiträge zur allgemeinen Kolloidchemie. Von Dr. B. Sztidlar, Paris. Dresden: Theodor Steinkopff, 1908. Pp. 41. (Price, M. 1.50.)

Untersuchungen zur Kenntnis der psychomotorischen Bewegungstörungen bei Geisteskranken. Von Dr. Karl Kleist, Assistenzarzt der Klinik für Nerven- und Geisteskrankheiten zu Halle a. S. Leipzig: Dr. Werner Klinkhardt, 1908. Pp. viii-171. (Price, M. 6.)

Traité de l'alimentation et de la nutrition à l'état normal et pathologique. Par le Dr. E. Maurel, médecin principal de Réserve de la Marine, professeur à Faculté de médecine de Toulouse. Deuxième volume. Les rations à l'état normal. Ration moyenne d'entretien de l'adulte. Ration de croissance et après l'âge adulte. Paris: O. Doin, 1908. Pp. xv-666.

Die nervösen Erkrankungen des Geschmackes und Geruches. Von Prof. Dr. L. v. Frankl-Hochwart. Zweite, gänzlich umgearbeitete Auflage. Mit 14 Abbildungen. Wien und Leipzig: Alfred Holder, 1908. Pp. 196.

Die Lehre von der Intubation. Von Prof. Dr. J. von Bokay, Direktor des St. Anne Kinderspitals in Budapest, etc. Mit 113 Abbildungen und 2 Tabellen im Text. Leipzig: F. M. V. Vogel, 1908. Pp. 250. (Price, M. 10.)

Fourth Annual Message of John Weaver, Mayor of the City of Philadelphia. With the Annual Reports of the Director of the Department of Public Health and Charities, and Superintendent of the Bureau of Charities. For the Year ending December 31, 1907. Issued by the City of Philadelphia, 1907.

A Manual of Fever Nursing. By Reynolds Webb Wilson, M. A., M. D., LL. D., Professor of Medicine at the New York Postgraduate Medical School and Hospital, etc. Second Edition, Revised, Illustrated. Philadelphia: P. Blakiston's Son & Co., 1908. Pp. 299. (Price, \$1.)

Transactions of the Obstetrical Society of London. Volume xlix. For the Year 1907. With a List of Officers, Fellows, etc., and General Index to Vols. i to xlix. Part

III. For June and July. Edited by Herbert B. Spencer, M. D., and Robert Boxall, M. D., Senior Secretary. London: Published by the Society, 1907.

Forty-third Annual Report of the Trustees of the Boston City Hospital, Including the Report of the Superintendent.

## Official News.

### Public Health and Marine Hospital Service Health Reports:

The following cases of smallpox, yellow fever, cholera, and plague have been reported to the surgeon general, United States Public Health and Marine Hospital Service, during the week ending May 22, 1908:

Places.	Date.	Cases.	Deaths.
Alabama—Mobile.	May 9-16.	6	0
California—Los Angeles.	April 23-May 2.	1	0
California—San Diego and vicinity.	May 1-8.	1	0
California—San Francisco.	April 25-May 2.	5	0
District of Columbia—Washington.	May 2-9.	5	0
Illinois—Chicago.	May 2-9.	4	0
Illinois—Danville.	May 3-10.	2	0
Illinois—Jacksonville.	May 2-9.	1	0
Illinois—Springfield.	April 30-May 7.	3	0
Indiana—Fort Wayne.	May 2-9.	1	0
Indiana—Indianapolis.	May 3-10.	2	0
Indiana—La Fayette.	May 3-10.	2	0
Iowa—Albia.	May 2-9.	1	0
Iowa—Ottumwa.	May 2-9.	1	0
Kansas—Kansas City.	May 2-9.	5	0
Kansas—Topeka.	May 2-9.	9	0
Kentucky—Covington.	May 2-9.	1	0
Louisiana—New Orleans.	May 2-9.	5	3 cases imported.
Michigan—Grand Rapids.	May 2-9.	1	0
Michigan—Kalamazoo.	May 2-9.	2	0
Michigan—Saginaw.	May 2-9.	4	0
Missouri—St. Joseph.	March 29-May 9.	93	1
Missouri—St. Louis.	May 2-9.	1	1
Nebraska—South Omaha.	May 2-9.	2	0
North Carolina—Charlotte.	May 1-8.	1	0
Ohio—Cincinnati.	May 2-9.	10	0
Ohio—Toledo.	April 25-May 2.	3	0
Tennessee—Nashville.	May 2-9.	1	0
Texas—Galveston.	May 1-8.	1	0

### Public Health and Marine Hospital Service:

*Official list of changes of stations and duties of commissioned and noncommissioned officers of the United States Public Health and Marine Hospital Service for the seven days ending May 20, 1908:*

- ASHFORD, F. A., Assistant Surgeon. Granted leave of absence for four days, from April 12, 1908, on account of sickness.
- BOWIE, R. I., Sanitary Inspector. Granted leave of absence for thirty days, from July 1, 1908, and extension of leave without pay for fourteen days, from August 1, 1908.
- BURKHALTER, J. T., Passed Assistant Surgeon. Granted leave of absence for one month, from June 3, 1908.
- CARRINGTON, P. M., Surgeon. Granted leave of absence for five days, from May 19, 1908, under paragraph 189, Service Regulations.
- FROST, W. H., Assistant Surgeon. Granted leave of absence for two days, May 2 and 3, 1908, under paragraph 210, Service Regulations.
- LANZA, A. J., Assistant Surgeon. Relieved from duty on the revenue cutter *Manning*, and directed to proceed to Port Townsend, Wash., reporting to the commanding officer of the revenue cutter *Rush* for duty.
- MASON, W. C., Acting Assistant Surgeon. Granted leave of absence for two days, from May 28, 1908.
- McLARTY, A. A., Acting Assistant Surgeon. Granted leave of absence for fourteen days, from May 15, 1908.
- ROSELLO, M. M., Acting Assistant Surgeon. Granted leave of absence for four days, from April 25, 1908.
- VOGEL, C. W., Passed Assistant Surgeon. Relieved from special temporary duty at San Francisco, Cal., and directed to proceed to San Juan and other quarantine stations in the island of Porto Rico, and also to certain places in Venezuela, for special temporary duty.
- WARREN, B. S., Passed Assistant Surgeon. Granted leave of absence for two months, from June 5, 1908.
- YOUNG, G. B., Surgeon. Detailed to represent the Service at the meeting of the American Medical Association, Chicago, Ill., June 2 to 6, 1908.

### Boards Convened.

A board of medical officers was convened to meet in New Orleans, La., for the purpose of making a physical examination of Passed Assistant Surgeon T. D. Berry, in accordance with paragraph 50 of the Service Regulations. Detail for the board: Surgeon J. H. White, chairman; Passed Assistant Surgeon H. W. Wickes; Assistant Surgeon C. M. Fauntleroy, recorder.

A board of medical officers was convened to meet in Chicago, Ill., May 22, 1908, for the purpose of examining applicants for the position of cadetship in the Revenue Cutter Service. Detail for the board: Surgeon G. B. Young, chairman; Assistant Surgeon C. E. Wood, recorder.

A board of medical officers was convened to meet in St. Louis, Mo., May 23, 1908, for the purpose of examining an applicant for the position of cadetship in the Revenue Cutter Service. Detail for the board: Passed Assistant Surgeon B. S. Warren, chairman; Acting Assistant Surgeon H. C. Wakefield, recorder.

### Army Intelligence:

*Official list of changes in the stations and duties of officers of the medical corps of the United States Army for the week ending May 23, 1908:*

- COLE, C. L., First Lieutenant. Ordered from Ft. Thomas, Ky., to Ft. Benjamin Harrison, Ind., for duty.
- DUTCHER, B. H., Major. Relieved from duty in the Philippine Division in time to sail for the United States about July 15th; granted two months' leave of absence.
- EMERT, R. G., Major. Arrived at San Francisco from tour of the Philippine Service.
- IRELAND, M. W., Major. Detailed to represent the Medical Department of the United States Army at the meeting of American Medical Association, at Chicago, June 2 to 5, 1908.
- LYNCH, CHARLES, Major. Granted leave of absence to June 30, 1908.

### Navy Intelligence:

*Official list of changes in the stations and duties of officers of the medical corps of the United States Navy for the week ending May 16, 1908:*

- BAKER, M. C., Assistant Surgeon. Detached from the navy yard, Mare Island, Cal., June 1st, and ordered to the *Ohio*.
- BAKER, M. W., Passed Assistant Surgeon. Detached from the *Colorado* and ordered to the *Nebraska*.
- CATHER, D. C., Assistant Surgeon. Detached from the *Lancaster* and ordered to the naval recruiting station, Kansas City, Mo.
- DUNN, H. A., Passed Assistant Surgeon. Detached from the *Nebraska* and ordered to the *Colorado*.
- FARENHOLT, A., Surgeon. Detached from the *Independence* and ordered to the *Maryland*.
- GARRISON, H. A., Assistant Surgeon. Detached from the Naval Hospital, Philadelphia, June 20th, and ordered to the naval station.
- KENNEDY, J. T., Surgeon. Detached from the naval recruiting station, Dallas, Tex., and ordered to the *Independence*.
- MAYERS, G. M., Passed Assistant Surgeon. Ordered to the navy yard, Mare Island, Cal.
- MORAN, C. L., Assistant Surgeon. Detached from the Naval Hospital, Norfolk, Va., and ordered to the naval recruiting station, Dallas, Tex.
- SHIPP, E. M., Surgeon. Detached from the *Illinois* and ordered to the *Pennsylvania*.
- URIE, J. F., Surgeon. Detached from the *Pennsylvania* and ordered to the *Illinois*.

### Births, Marriages, and Deaths.

#### Married.

- ASTLEY—CASSELLBERRY.—In Philadelphia, on Sunday, May 17th, Dr. George Mason Astley and Dr. Clara Melvia Casselberry.
- COLLINS—HENDERSHOT.—In Platteville, Wisconsin, on Thursday, May 14th, Dr. W. P. Collins and Miss Mae Hendershot.
- DOWD—GROTE.—In Indianapolis, Indiana, on Tuesday, May 12th, Dr. Francis Tobias Dowd and Miss Nannette Grote.
- HUGGINS—COLLADAY.—In Washington, D. C., on Thursday, May 14th, Dr. John B. Huggins, Medical Corps, United States Army, and Mrs. Rose Loretto Colladay.

#### Died.

- ALLING.—In Dunkirk, New York, on Friday, May 8th, Dr. Charles P. Alling, aged seventy years.
- BEACH.—In Hartford, Connecticut, on Friday, May 15th, Dr. Oliver J. Beach, aged thirty-five years.
- BEHM.—In Chicago, on Saturday, May 16th, Dr. Charles E. Behm, aged thirty-eight years.
- CARRINGTON.—In Farmington, Connecticut, on Wednesday, May 20th, Charles Carrington, aged sixty-nine years.
- CUDDY.—In Baltimore, Maryland, on Thursday, May 14th, Dr. J. W. C. Cuddy.
- HARMAN.—In Wakefield, Nebraska, on Tuesday, May 12th, Dr. B. T. Harman, aged sixty-five years.
- LONG.—In Somerville, New Jersey, on Wednesday, May 20th, Dr. William H. Long.
- MARCOUR.—In New Orleans, Louisiana, on Sunday, May 17th, Dr. Raphael O. Marcour, aged thirty-four years.
- PEARSON.—In Toronto, Canada, on Sunday, May 17th, Dr. B. F. Pearson, aged sixty-eight years.
- PETPIS.—In West Branch, Michigan, on Monday, May 18th, Dr. A. J. Petpis, aged thirty-eight years.
- SALESMAN.—In New York City, New Jersey, on Monday, May 18th, Dr. E. A. G. Salesman.
- STILLMAN.—In New London, Connecticut, on Thursday, May 21st, Dr. Martha Rose Stillman, of Plainfield, New Jersey.
- STRUTHERS.—In Sudbury, Canada, on Thursday, May 14th, Dr. R. B. Struthers, aged forty-nine years.
- TWEEDY.—In Buffalo, New York, on Wednesday, May 13th, Dr. Edward H. Tweedy, aged forty-three years.

#### EXPERT TESTIMONY.\*

By JUDGE RUFUS B. COWING,  
New York.

Some days ago I was invited by the worthy president of the New York Academy of Medicine to attend this meeting and make some remarks on the value of medical expert testimony, based upon my experience and observation on the criminal bench of this county. It can hardly be expected that I shall be able before such a body of medical scientists to present many new ideas, for my subject has frequently been a matter of discussion between physicians and lawyers. It may be said, however, that I am here to-night as a sort of expert to address you on the value of medical expert testimony, as during my twenty-eight years on the bench in the court of general sessions of this county I presided over many criminal trials where medical experts were called upon to give their opinions.

The safeguards provided by the criminal law to protect the innocent are many, and after a long experience and much observation I have come to the conclusion that it is practically impossible to convict an innocent person of crime when all these safeguards are invoked and observed in a criminal prosecution against him.

Every person charged with the commission of a crime: 1. Is presumed to be innocent until he is proved guilty. 2. Has the right to be defended by his own counsel, and to call witnesses in his defense. 3. Has the right to assist in selecting his own jury. 4. Has the right to challenge, with or without cause, any jurymen whom, for any reason, he considers unfavorable to him. 5. Has the right to see and examine the indictment against him, and make such objection to it as his counsel may suggest. 6. Has the right to face his accusers in an open and public court. 7. Has the right, through his counsel, to thoroughly and rigidly cross examine the witnesses against him in order to determine the truthfulness of their testimony. 8. Has the right to object to the admission or exclusion of any evidence which his counsel may think is unfavorable or favorable to his side of the case. 9. Has the right to object to anything said or done during the progress of the trial which he considers prejudicial to him or his case. 10. Cannot be convicted upon a preponderance of evidence, but can only be convicted upon such evidence as satisfies the consciences of twelve men,

whom he has himself assisted in selecting, beyond all reasonable doubt. 11. Has the right of appeal, either with or without exceptions, if the verdict is against him, so that practically his whole case may be retried by an appellate court, and a new trial granted him if the appellate court, after a review of the whole case, comes to the conclusion that justice demands it. 12. Has the right to take the witness stand in his own behalf, if he elects to do so; and if he refuses to do so the jury have no right on that account to draw any unfavorable inferences against him.

All these safeguards and many others are undoubtedly provided for the protection of the innocent, and not of the guilty, and, as I said before, make it practically impossible to convict an innocent person of a crime.

When a person kills another under such circumstances that the only possible defense is that he was insane at the time of the killing, he calls as witnesses all persons acquainted with his past life, who narrate to the jury all the strange, odd, and eccentric things which he has ever done or said, and, if possible, testify that one or more of his lineal ancestors were insane, and that the defendant has suffered from diseases which would be likely to disturb his equilibrium. The people controvert the defense by putting in all attainable evidence to show that the defendant at the time of the killing was not only sane, but criminally liable.

Both sides then produce medical experts to sustain their respective contentions, and it is a remarkable fact that both sides can generally obtain as many experts as they are willing to pay for.

Both sides then proceed to draw up a long hypothetical question, based, as a rule, not upon the whole evidence, but only upon so much of it as seems to sustain their theory, and from their respective experts obtain answers so contradictory that the jury is often obliged to discard the whole of it and decide the case upon the evidence and its own unaided judgment.

I have never heard of a case in which the sole defense was insanity, where the defendant was put upon the witness stand, and I have often wondered what the result would be if he should be called as a witness in his own behalf, and on cross examination be asked a few relevant and material questions, such as:

Are you in the habit of carrying a revolver loaded with powder and ball? Do you remember the time when and the place where you shot and killed the deceased? Did you know at the time you shot the deceased that if you shot him in the heart or any vital part of his body it would probably kill him?

\*Read before a meeting of the New York Academy of Medicine. The other line alluded to in the foregoing case.

Did you know that in shooting the deceased you were doing an unlawful act? And other similar questions which might be put to him by a skilled cross examiner.

Legal evidence is that which is properly submitted to a competent tribunal as a means of ascertaining the truth of any alleged matter of fact under investigation before it. Tersely put, it is a means to an end, the end being the ascertainment of the truth. While opinions of experts are not facts, yet under certain circumstances they are admitted in evidence as aids to the court and jury in the ascertainment of facts.

Our present judicial procedure, instituted for the purpose of administering the civil and criminal justice in our courts, is constantly undergoing change, and it cannot justly be claimed that the same is in all respects perfect.

It is believed by many that our present jury system very inadequately answers the purpose for which it was instituted, and that trial by jury should be superseded by some other more certain and reliable method for the ascertainment of the truth. While I don't think that our present method is perfect, I do think that it is the best system which has yet been suggested or devised, and from my experience and observation I believe that the jury generally arrive at a just conclusion on the facts in any given case and commit less errors than some judges in determining questions of law in the same case.

It is a fundamental principle of the criminal law that every sane person who has arrived at the age of discretion is conclusively presumed to know the law. I only know of one exception where this rule does not apply, and that is to our able judges, and for that reason the State provides appellate courts to review their decisions and correct their mistakes of law.

From my observation and experience I am of the opinion that a competent, honest, and impartial medical expert may and often does aid a jury materially in determining the facts in a case on trial, but I am also of the opinion that the practice now in vogue in reference to medical expert testimony must be radically changed before it will receive from courts, juries, and the general public that consideration to which it is justly entitled.

A medical expert is a doctor of medicine or surgery who, by special study and experience, has acquired skill and a peculiar knowledge upon certain subjects pertaining to his profession, which qualify him as an expert and render him competent to give his opinion in a judicial proceeding upon such subjects.

The opinions of experts are not, however, admissible upon matters of common knowledge. As these are within common observation and experience the jurors are deemed qualified to judge without expert aid.

Besides being an expert it must not be forgotten that he is also a witness, and, in fact, is only distinguishable from a nonexpert or lay witness in that he is permitted to give his opinion in answer to a hypothetical question based upon assumed facts in evidence which are not within his own personal

knowledge, while a nonexpert or lay witness can only base his opinion upon facts within his own personal knowledge, which have first been disclosed to the jury by him.

Neither the opinion of the expert or nonexpert witness is conclusive upon the jury, who are the sole judges of the facts, but is to be weighed like all other evidence, and the jury should always consider quality as well as quantity; in fact, the jury may come to a conclusion against the greater number of opinions and in favor of the lesser.

The opinion of one competent expert may, on account of his greater knowledge and experience of the subject, or from his giving a fuller detail of the facts or more probable reasons, be of greater value to the jury than the opposite opinions of several.

We sometimes hear lawyers seriously argue to the jury that quantity should have as much weight with them as quality. I call to mind a case which was tried before me in which the lawyer for the defendant, after the close of the people's case, informed his client that he must be on hand the next morning at the opening of court with at least seven witnesses, he having ascertained after counting up that the people had called six.

In propounding a hypothetical question to a medical expert, as the law now stands, the counsel has the right to assume, within the limits of the evidence, any state of facts which he thinks the evidence justifies, and ask the witness to give his opinion upon the facts thus assumed, which facts are assumed only for the purpose of the question, and for no other purpose. If the jury find that the facts stated in the hypothetical question are not proved, the opinion goes for nothing. The counsel may embrace in his hypothetical question such facts as he may deem established by the evidence, and if the opposing counsel does not think that all of the relevant facts in evidence are contained in such question, he may include them in a question propounded by him on cross examination.

The principal defects in medical expert testimony are as follows: 1, Its partisan character. 2, The insufficiency of the present standard of qualification. 3, The excessive number of experts examined. 4, The right given to experts to give their opinions based upon facts or alleged facts not within their own personal knowledge.

1. Very much of the just and harsh criticism which has from time to time been made by our courts against expert testimony and which has brought such testimony into disrespect and disrepute among the public generally is its partisan character, which is invariably shown from the fact that an expert always gives his opinion in the interest of the party by whom he is called and paid, and the further fact that he very frequently participates in the trial in the double capacity of witness and adviser to counsel trying the case. How to overcome these objections so as to make experts more fair and impartial is one of the questions to be determined. I will later discuss this phase of the question more in detail.

2. In a criminal case where the insanity of the defendant is the defense, besides the usual questions put to the proposed expert witness as to the extent of his study of medicine and surgery, and

his experience in treating diseases of the mind, he should be asked whether he has made a special study of psychology, and whether he is familiar with the law's definition of insanity, and whether he believes that law just and right.

A medical expert should be versed in psychology as well as physiology, particularly in these days, when it is being recognized more and more that both form a part of the science of healing.

In the colloquy between Macbeth and his wife's physician, Shakespeare showed that in his day the medical profession was not as far advanced in this respect as in our time.

MACBETH: How does your patient, doctor?

DOCTOR: Not so sick, my lord, as she is troubled with thick coming fancies  
That keep her from her rest.

MACBETH: Cure her of that.

Canst thou not minister to a mind diseased?  
Pluck from the memory a rooted sorrow,  
Raze out the written trouble of the brain,  
And with some sweet oblivious antidote  
Cleanse the stuff'd bosom of that perilous grief  
Which weighs upon the heart?

DOCTOR: Therein the patient must minister unto himself.

MACBETH: Throw physic to the dogs; I'll none of it.

The mere fact that a witness is a practising physician should in no case render him a competent expert witness in cases where insanity is the issue. He may be a competent expert in diseases of the eye, the ear, the heart, the kidneys, or any other part of the human anatomy, but an incompetent expert witness in diseases of the mind.

I have heard medical experts say that they did not believe that the law's definition of insanity is either just or right. By the law of this State a person is not excused from criminal liability as an insane person except upon proof that at the time of committing the alleged criminal act he was laboring under such a defect of reason as either not to know the nature and quality of the act he was doing, or did not know the act was wrong. It is very readily seen that every degree of insanity will not excuse a criminal act, but only such degree as comes within the law's definition. A person, to establish his defense of insanity as an excuse for an otherwise criminal act, must be able to show that his mind was so diseased at the time of committing the act that he did not have sufficient mental capacity to form a criminal intent, and that he did not know the nature and quality of his act or that the act was wrong.

3. With reference to the number of experts to be called by the respective sides, it should never be left to the discretion of counsel, but to the discretion of the court, and, as a rule, never more than two for each side should be allowed. This would compel the respective parties to produce the best experts obtainable, and would save time and much confusion to the jury, which often results from a multiplicity of experts.

4. In my judgment the practice of allowing a medical expert to give his opinion upon a hypothetical question based upon assumed facts not within his personal knowledge should be done away with.

Every witness who is permitted to give an opinion should be compelled to first give the facts within his own personal knowledge and observation upon

which his opinion is predicated, which would enable the jury to determine whether the disclosed facts justify his conclusion.

These long drawn out hypothetical questions, which are based only upon a portion of the evidence and usually upon that portion only which is most favorable to the party asking the question, which sometimes contain two or three thousand words and require an hour or more to read, and which as a rule are unfair and misleading, in my opinion, instead of aiding the jury in coming to a correct conclusion, mystify and confuse them to such an extent as sometimes to cause a miscarriage of justice.

It must be remembered that in criminal cases the defense of insanity is often manufactured and is the only conceivable defense which can be made.

An expert who is not possessed of sufficient ability to personally examine the defendant and ascertain for himself the facts upon which he predicates his opinion should not be allowed to give it.

The rule regulating the admissibility of the opinions of nonexpert or lay witnesses upon questions affecting the mental condition of a person should be applied to expert witnesses. We find the rule laid down in the case of "People vs. Conroy," decided in the Court of Appeals in 1884, as follows:

"When a layman is examined as to facts within his own knowledge and observation tending to show the soundness or unsoundness of the defendant's mind, he may characterize as rational or irrational the acts and declarations to which he testifies. But to render his opinion admissible even to this extent, it must be limited to his conclusion from the specific facts he discloses."

To revert to the question of allowing medical experts to act in the dual capacity of counsel and witness. There has grown up a practice in the courts of calling medical experts to aid the respective counsel in conducting the trial by suggesting questions to be put to medical expert witnesses, thus making them practically counsel in the case, and afterwards calling them as witnesses to sustain the side of the case for which they have been acting in the capacity of counsel. All this is done in the presence and hearing of the jury, and has the effect of convincing them that experts are not fair and impartial witnesses, but are prejudiced in favor of the party calling and paying them.

This practice has had much to do in bringing medical expert testimony into disrepute, and should be done away with.

There can be no valid objection for either side in a criminal case to employ able medical experts to assist counsel in conducting the trial, but having so acted they should never be permitted to go upon the witness stand as experts. In other words, they should never act in the double capacity of witness and counsel.

Various means have been suggested by lawyers and doctors for minimizing the evil which attends the reception of medical expert testimony at the present time.

Among such remedies are: 1. The appointment by some competent power of medical expert witnesses, who must qualify themselves to give opinion evidence in the case without consultation with the litigants or their counsel, and whose services are free.

be paid for by the county in which the trial takes place. 2, A statutory prohibition against receiving any expert evidence from a witness who has been paid or expects to be paid anything by either party, which is practically going back to the old rule of evidence, which disqualified a witness who had any pecuniary interest in the result of the trial. 3, The appointment of a commission of experts in insanity cases to examine the person alleged to be insane before trial and make a report to be read at the trial, where all the members of the commission must attend to be examined and cross examined, as either party may desire, without compensation except a fee to be fixed and paid by the State.

For many years the law of England and this State made any one who had a pecuniary interest in the result of a lawsuit an incompetent witness to testify in such suit.

While this rule of evidence has been relaxed so that pecuniary interest no longer disqualifies, yet juries and courts have a right and should consider such interest in determining the credibility of the witness.

The reason of the old rule rendering such a witness incompetent was that his testimony was considered to be so prejudiced as to render it unreliable for the jury to consider in coming to a conclusion, and it seems to me that the reason of this old rule applies with great force to medical experts, and how to change the present system of obtaining and paying such experts, so as to render their testimony less liable to be discredited, is the question which the medical and legal professions are now trying to determine.

The proposed plan of having some disinterested power select and pay such experts is not unattended with difficulties, but one thing is certain: This society and other similar bodies can formulate wise rules of medical ethics, which shall bind all their members and materially aid in solving the question.

## THE RESTORATION OF THE NORMAL BALANCE OF THE FOOT.

### III.

*Third Paper. Operative Measures in Weak or Flat Foot Upon the Tendons of Those Muscles Which Normally Control the Arch Movements, for the Purpose of Correcting the Deformity.*

BY E. G. ABBOTT, M. D., AND H. A. PINGREE, M. D.,  
Portland, Me.

The use of a mechanical support alone for the cure of weak or flat foot is ineffective, as stated in the preceding paper (see *Journal*, p. 976), since it tends to weaken the already overstretched structures which, when in a normal condition, hold the foot in a correct position.

The use of a support simply as a means of relief is objectionable, as patients are not only averse to wearing such a cumbersome apparatus over a long period, but the expense and trouble are factors to be considered. The orthopaedic surgeon also realizes that the result obtained is only palliative, as the gait is never normal, although the plate may be an excellent fit, and there is a prompt return of the deformity as soon as its use is discontinued.

In order, then, to effect a cure with the use of a support it is necessary to supplement it with a long

continued course in muscular exercises, as the arch can be maintained in a normal position, if unsupported, by muscular development only.

The restoration to a normal condition as a result from this combined method of treatment need not

FIG. 33.—Showing hypertrophy of anterior and posterior tibial tendons in weak foot.

be expected in all cases, even under the direction of the most skilled surgeon and with the assistance of the patient, as conditions are such in many instances that the parts at fault fail to respond to the treatment, and the result too often is a foot which remains in a normal position only so long as the support is used.

There are a large number of patients for whom it is useless to prescribe muscular exercises for any considerable period, as many are so busily engaged that they neglect them, many are too indolent, while

FIG. 34.—Showing shortened peroneal tendons which prevent the arch from being raised to a normal position.

a greater number are so ignorant and poor that they cannot be kept under the necessary observation during such a course of treatment.

In consideration of the foregoing it would seem best, if possible, that some method should be adopted for the treatment of these cases which would be effective, would be adapted to the conditions met

FIG. 35.—3. Arch flattened and held by person. 36.—4. Arch in normal position as soon as tendons are divided.

in the majority of patients, would not involve the expenditure of a considerable length of time, and would insure a larger percentage of cures than that obtained under our present plan of treatment.

A review of the literature upon conservative measures shows that almost all conceivable methods and agents have been utilized, either alone or in combination, with about the same results, and the question naturally arises, is not the operative plan of treatment the only one which offers a solution of the difficulties which are so apparent?

Several operations for the relief of this deformity have been devised which have been more or less successful in a certain class of cases, but none has been generally adopted, and at the present time there does not seem to be any surgical procedure which will successfully overcome the condition met with in a majority of these patients.

A brief reference to the description in the preceding paper of the structural changes which have taken place in a weak foot, and a consideration of

analysis of its structures should begin with the foot in a state where it is freely movable in all directions, i. e., as far as interjoint motion is concerned. The only abnormal condition then would be the patient's inability to maintain unaided the foot in a normal position, and this disability would be due either to weakness and overstretching of those structures that support a normal arch, which would prevent the foot from being held in the correct position, or, together with this, to shortening of those muscles which depress the arch, which would make it impossible to even bring the foot into a correct position.

The foot is found to be everted, the bones are displaced and often misshapen, the ligaments are stretched and attenuated, and some muscles are lengthened, although they usually show marked hypertrophy of their tendons (Fig. 33), while others are often shortened (Fig. 34).

From our present knowledge it would seem, from the before mentioned examination, that the only

FIG. 37.—5. Foot in position before dividing tendons.

part which would admit of any surgical interference would be the muscles, since the bones cannot be changed in shape by operative measures, as it would destroy the joint surfaces, and the ligaments are so situated and are so numerous that any attempt to alter them in this manner would be futile. The only change, then, that could be made surgically to better this condition, with a reasonable hope for a return to the normal as a result, would be in the muscles or their tendons, and this change can be brought about only by shortening those which normally maintain the arch and lengthening those which prevent it from assuming the normal position.

The preliminary paper on this subject (see *Journal*, p. 875) showed, in the experiments described, that the anterior and posterior tibials are the muscles which hold the arch in place, and that the peronei muscles and the *psoas* *Adiffis* prevent it from being

FIG. 36a.—6. Arch flattened and held by person. 36b.—7. Arch in normal position as soon as tendons are divided.

what might be done in the way of operative work to bring the foot to a normal condition, will help us in determining whether such measures would be feasible.

As already stated, the complications in weak feet must be overcome before curative measures of any kind can be successfully carried out; therefore, the

brought into a normal position readily if they are shortened. It also showed that it requires only a small amount of power, in comparison with that necessary to lift the weight of the body, upon the anterior and posterior tibial muscles to hold the arch

FIG. 38.—Position of limb in plaster of Paris after operation.

in place, when the patient bears his whole weight upon the foot, provided that the peronei tendons and the tendo Achillis are divided, so that, when the experiment is made, the arch can be brought into a normal position.

It would not seem unreasonable, then, to suppose that this deformity may be corrected by a division of those structures which resist the restoring of the arch to a normal position, and a shortening of those which normally maintain it in place.

It was from conclusions drawn from such an analysis of these experiments that the following briefly described operation was undertaken, and the results so far obtained have given the operators reason to believe that the work justifies further consideration.

After the usual preparation, the foot is grasped by the operator, with an assistant holding the leg, and inverted with a moderate degree of force. With the foot in this position the peronei tendons, which are upon the stretch, are severed subcutaneously at a point about half way between the external malleolus and the sole. This procedure allows the foot to be inverted to its fullest extent by the surgeon, and the arch assumes the highest position possible (Fig. 35). The tendo Achillis is now divided, so that the foot is hyperflexed when force in this direction is brought to bear upon it (Fig. 36). By this means the calcaneum is permitted to slide forward upon the astragalus, thus elevating its anterior extremity, relaxing the plantar ligament, and bringing the tubercles to their normal position of weight bearing. A short oblique incision is made over the tendon of the anterior tibial muscle, just in front of the internal malleolus, at a point where it commences to turn over the internal border of the foot. The sheath of the tendon is opened, and a grooved director—or, better, an instrument devised for picking up tendon—is passed beneath the tendon, and it is lifted above the surrounding tissues. The

grooved director or tendon elevator supporting the tendon is twisted in a circular manner until the desired amount of shortening is made (Fig. 37), when the contiguous parts of the proximal and distal ends of the tendon are securely fastened together by means of a linen suture. By this method just the proper amount of tension upon the tendon can be made, and the difficulty usually experienced in trying to hold the cut ends in place while a suture is passed and tied is avoided. The loop of the tendon is severed, and the free ends are trimmed to a suitable length and sutured to the tendon. The sheath is carefully stitched together, and the skin preferably closed by buried sutures. The tendon of the posterior tibial is treated in a manner similar to the one described, the incision being at a point where it passes beneath the inner malleolus. The foot is held in the position of flexion and extreme inversion, the leg is flexed, and the limb enveloped in plaster of Paris, including the foot, leg, and lower part of the thigh (Fig. 38). The plaster dressing remains in place for four weeks; then it is removed, and massage and passive motion commenced. A week later the patient is allowed to walk with the arch supported until the tendons are firmly united, and the muscles sufficiently developed to hold the foot in the corrected position.

The most important step of the operation is the division of the peronei tendons and the heel cord, for the arch in a large number of cases undoubtedly would return to a normal position without any further surgical interference, since there is a strong tendency for the foot to assume the correct position, in most instances, as soon as these structures are divided, for the opposing muscles no longer exert any force, and without this opposing force the muscles which hold up the arch would in a brief time shorten to their normal length.

The question which naturally confronts one at this point is, Will these shortened tendons remain so and hold the arch in a normal position when

FIG. 39.—Case immediately before operation

they are subjected to strain, or will they stretch and allow the foot to flatten again? If the conditions after the operation are the same as before the deformity occurred, and the same factors which caused it in the first place are present, it would

seem that a recurrence would take place, as the tendons are no stronger, and the ligaments weaker. From observations made thus far, however, this reasoning does not seem to be verified clinically, and might be explained by these facts: First, that those

FIG. 40.—Same case as in Fig. 39, three weeks after operation.

factors which primarily caused the deformity are eliminated, in that proper attention is given to the foot wear, and the patient is instructed as to the care of the feet, so that improper postures are guarded against, and muscular exercises are encouraged; second, that, although the condition after the operation is similar, it is not the same as when the deformity commenced, since the normal balance has been restored, therefore the arch is easily maintained in a normal position, as the muscles act to a better advantage, in that the leverage is improved, and in consequence of this the required muscular power is much lessened.

It is not uncommon to find deformities in which the condition at a certain stage is nearly analogous to that found in the foot after this operation, which will illustrate the point in question. For instance, in acquired clubfoot, when the deformity first begins, it is due to the shortening of the anterior and posterior tibial muscles, which are not only able to

FIG. 41.—Same case as in Fig. 40, nine months after operation, the patient having walked for nine months.

increase the arch and invert the foot, but will turn it bottom side up in a comparatively short time. To those who have had experience in correcting this deformity of clubfoot, even in those cases just beginning, it is very apparent that these two muscles

are well able to maintain the arch of the foot in place, if they can work to an advantage.

It does not seem unreasonable to believe, then, that these muscles (tibialis anticus and posticus) will not only hold the arch in position, but will continue to shorten after the operation until they are sufficiently opposed by the lengthened peronei muscles, since the normal balance in any segment of the body is maintained only in this manner.

From the results so far obtained in this operation there does not appear to be any tendency toward a return of the deformity, but, instead, the improvement has been constant, and it seems possible to correct this distortion by this method. At this time, however, there has not been a sufficient number of cases operated in, nor has there been sufficient time since the operations to warrant positive statements as to the final outcome (Figs. 39, 40, 41).

In all patients who have submitted to the operation there has been a marked change for the better, and in those cases where the result has not fully met the expectations of a complete restoration of a normal arch, the fault was an error in judgment as to just how much of the tendon should be removed, rather than any defect in the operation as a whole.

## THE SPECIFIC ACTION OF MERCURY IN SYPHILIS.

BY HENRY G. PIFFARD, M. D., LL. D.,  
New York,

Professor, Department of Dermatology, New York University, Consulting Surgeon, City Hospital, etc.

For several years Roux and Metchnikoff have carried on a series of experiments at the Pasteur Institute in the attempt to inoculate the anthropoid apes and some of the lesser members of the simian family with syphilis. In these experiments they have obtained positive results. The ultimate aim of these researches was to find, if possible, some means whereby the effects of the inoculation could be prevented before the virus gained entrance to the general system. In this way they have apparently succeeded by the application of a mercurial ointment composed of one part of calomel and two parts of

lanolin. This should be applied within twelve or eighteen hours of the time of inoculation, and when properly carried out general infection does not occur. In other words, the mercury applied locally destroys the spirochætae.

During the progress of the investigation notices thereof have appeared in *Annales de l'Institut Pasteur*, and the general results have been embodied in a *Thèse* by Paul Maissonneuve. This has been translated by de Verteuil under the title, *The Experimental Prophylaxis of Syphilis*. From this little work I quote a number of paragraphs:

"The use of mercury applied locally in syphilis has been advocated by eminent authorities on syphilis, such as Deday, and more recently by Fournier."

Concerning mercury, Roux and Metchnikoff quote Hallopeau (1906) as saying: "I systematically employ this local treatment in every syphilitic lesion accessible to its influence. . . . Unless I am mistaken, this systematic use of local mercurial treatment, which I have already advocated on several occasions, should not be looked upon as being of little importance. I personally consider it to be of great practical value" (p. 36).

Speaking for themselves, Roux and Metchnikoff declare that "Mercury is even a greater specific against the local disease than against the general disease" (p. 55).

Concerning the relation of potassium iodide to the treatment of syphilis, I quote the following (p. 29): "It is, however, a matter of common knowledge that it has no influence on the chancre and on secondary lesions; it has never been considered as an antimicrobial agent. We must not, therefore, expect to find in this drug an antidote against the poison of syphilis."

While these views as to the local action of mercury and of the influence of the iodide in the treatment of syphilis will be new to many, they are not altogether novel, as will be seen by reference to my own writings of more than thirty years ago (*An Elementary Treatise on Diseases of the Skin*, 1876), from which I quote the following:

"How does mercury cure the syphilides? Is it by some alteration of the constitution of the blood, and the consequent induction of nutritional changes, or is it by direct local action of the drug upon the lesion itself? The former is the more prevalent belief, but the latter, I think, is nearer the truth. Mercury cures the lesions by the particles being brought in direct contact with them, and *ceteris paribus*, the larger the quantity of mercury that can be made thus to act, the sooner the cure, provided the remedy be used in such a way as not to exhibit its own peculiar effects" (p. 69).

In a later writing (*Cutaneous and Venereal Memoranda*, 1877), I again referred to the local effects of mercury as follows: "If there be mucous patches or other lesions about the mouth, the trituration (of mercury) "is to be preferred to the pill, inasmuch as the finely divided drug is thus brought into immediate contact with the lesions themselves, and by its local action hastens their removal." Still later (*Practical Treatise on Diseases of the Skin*, 1891), I wrote concerning mercury as follows: "My own practice is to use this agent both internally and externally, believing as I do that the drug acts by

virtue of its particles being brought into direct contact with the lesions, externally by means of lotions, salves, or other applications; internally, through the medium of the blood and circulation" (p. 56).

Concerning the iodide, I wrote (1876) as follows: "Let us now consider the uses of the iodide in connection with the treatment of syphilis. Mercury removes symptoms and cures the disease, but sometimes does so slowly. The iodide does not cure the disease, but may remove certain symptoms with wonderful promptness" (p. 73).

It is certainly gratifying to know that the views as to the action of these drugs, presented more than thirty years ago as the result of observation and ratiocination, have been so amply confirmed by the recent experimental laboratory work of the Pasteur Institute.

256 WEST FIFTY-SEVENTH STREET.

### INTUSSUSCEPTION OF THE SIGMOID.\*

By JEROME M. LYNCH, M. D.,  
New York,

Lecturer on Rectal Surgery, New York Polyclinic and St. Bartholomew's Clinic.

Intussusception of the sigmoid is a condition which is much more frequent than we are aware, and has such an important relation to constipation, autointoxication, hæmorrhoids, mucous and membranous colitis, that a short paper on the subject, with a brief review of cases, may be of interest. By the sigmoid I mean that portion of the intestine between the bifurcation of the common iliac artery and the peritoneal reflection of the cul-de-sac of the rectum. In other words, the *iliac S* of the French.

**Ætiology.**—When the mesentery of this organ is abnormally long, it may be congenital or acquired. As the sigmoid is the storehouse, or faecal retainer, we can readily see how a long mesentery will, if the calls of nature are not promptly heeded, cause embarrassment to the sigmoid. Inflammation, infection, and ulceration are very apt to follow under pressure of hard fecal matter on the mucous membrane, when it is allowed to accumulate for any length of time. In order to evacuate the bowels drastic cathartics are given, and, when these fail to give relief, enemas in abnormal quantities are resorted to; as a result, straining at stool occurs, bringing the abdominal muscles and diaphragm into play, which, owing to the pressure from above and the relaxed state of the organ, eventually brings on intussusception.

It is naturally trivial at first; but when once started the difficulty of expulsion and the demands on the abdominal muscles and diaphragm for extra force are increased. The mesentery may become elongated from constant dragging, due to displacement of the surrounding organs, following childbirth, or from inflammation. Acute diarrheal conditions, due to constitutional disease or infection, following amebic dysentery, are etiological factors to be considered. Also growths, like polypi, by causing straining and a frequent desire to evacuate the bowels, are contributory factors.

**Pathology.**—Byron Robinson tells us that in these conditions the submesosigmoidal tissues, vessels, and veins are elongated and attenuated. Interference with the circulation causes disturbed secretion and peristalsis. There is an increase in the number of goblet cells, infiltration with round cells, infection, ulceration; also, a thickening of the mucosa and submucosa. When these conditions have existed for any length of time, very extensive ulceration of the sigmoid occurs, and sigmoiditis or perisigmoiditis is the result.

**Symptoms.**—A feeling of unfinished stool, following a movement of the bowels, aching pain in the sacrum, a passage of mucus or membrane, a dragging sensation in the left iliac region, with a feeling of heat across the lower portion of the abdomen and back, periodical attacks of hæmorrhage from the bowels, colicky pains before the bowels move, pain on sitting or standing for any length of time, headache, vertigo, nausea, vomiting, frequent and painful urination, pain down the back of the legs. The symptoms vary with the degree of intussusception,

Intussusception of lower portion of sigmoid colon (Hutchins).

length of time it has existed, and the involvement of other organs.

The feeling of unfinished stool, following a movement of the bowels, is the most constant and typical symptom, and when present should lead to digital and proctoscopic examination of the rectum. It is described as a feeling of something in the rectum that should come away. In a short time after the movement there is a desire to go to the toilet again, when very little is accomplished, unless an enema is taken. Assuming the knee chest posture will very often give relief.

Aching pain in the sacrum and pain down the back of the legs are other symptoms which are present in all cases, and are no doubt due to congestion, pulling on the mesentery, and pressure in the sacroplexus.

The feeling of heat in the ileopubic region and in the sacrum is not present in all cases, but when it manifests itself it causes a great deal of distress. This symptom is due to congestion, the same patients

\*Read before the West Side Clinical Society, April 1, 1908.

as a rule, feel relief after a hæmorrhage from the bowels.

Passage of mucus or membrane depends a good deal on the degree of intussusception; if this is marked, membrane is passed; if not, only mucus.

Periodical attacks of hæmorrhage usually occur in cases in which the intussusception is severe, and in which either constipation or diarrhoea are marked features. It is due, I presume, to the intense congestion caused by the obstruction to the return circulation. It also occurs when ulceration exists, and I have seen ulceration of the entire circumference of the bowel in these cases.

Colicky pains, before the bowels move, are due to an effort on the part of nature to get rid of the accumulated gas and faecal matter; the pulling of the intestine on its mesentery in an effort to straighten itself. Adhesions of the sigmoid, or some other neighboring organ, may also cause it.

Pain, on sitting or standing, only occurs in a small percentage of cases; this is due to pressure and congestion in the anal region.

Frequent and painful urination is no doubt a reflex symptom, due to the sympathy existing between the urinary and rectal sphincters.

*Treatment.*—The treatment may be divided into palliative and operative.

Palliative treatment is indicated in those cases where, owing to age or some constitutional disease, operative treatment is contraindicated. The general constitutional condition of the patient must always be considered and a suitable diet prescribed; the bowels moved every day with a mild laxative, and an enema of olive oil or saline solution employed to wash the lower bowel and prevent straining. When the condition is exaggerated, the patient should be instructed to move the bowels when lying either on the side or back, and a bed pan used. If there is discomfort and pain after the movement, rest should be advised, with the hips slightly elevated for an hour or two. The patient can be taught how to replace the intestine by passing a No. 3 Wales bougie, to the end of which is attached an inflating bulb; when the bougie meets with any resistance, a little air is introduced, and in this manner the bowel is gradually replaced. After this four ounces of oil, or some medicated solution, is introduced through the bougie in position, and the patient directed to rest for an hour, with hips elevated.

Office treatment, once or twice a week, is indicated in most of these cases, for by this means we are able to see if ulcerations exist, and, if so, to treat them locally; also, the act of passing the tube and the massage incident to the air pressure seems to have a decidedly beneficial effect. If this procedure is followed, impaction never takes place. And as we cannot always depend on the patient to carry out the treatment intelligently at home, it is well to keep him under our supervision until we are satisfied that there is material improvement.

*Operative Treatment.*—The patient is prepared in the usual way, as for any laparotomy. Beginning about two and a half inches above the pubis an incision some three inches long is made on the outer side of the left rectus muscle. The sigmoid is easily reached through this incision, and brought into

view. Three or four Pegenstecher sutures are now passed through the inverted transvalis fascia, on one side, through the muscular wall of the intestine, and again through the inverted edge of the transvalis fascia on the other side. In this way the intestine is suspended from the fascia, instead of from the peritonæum. (This point should be borne in mind, because if the sigmoid is suspended from the peritonæum, instead of from the transvalis fascia, it gradually relapses, with the result that a suspensatory ligament is formed, and a return of the old condition inevitable.) The fascia is then closed by means of interrupted sutures, and the skin with a continuous plain catgut. The patient should be confined to his bed for at least two weeks, and the bowels moved about the fourth or fifth day.

CASE I.—C. D., age twenty-three; occupation laborer.

Family history: Father and mother both living and well. Personal history: Has always suffered from constipation.

Present illness: About two or three years ago, he began to have pain before the bowels moved; the movements were never satisfactory, and he had a feeling as if there was something more to come away. He passed mucus and blood occasionally, and suffered from severe pain in his back and left iliac region, which was so severe at times as to prevent his working. He felt better when he rested awhile, but was hardly ever free from backache. Appetite was poor, and he suffered from indigestion. He had lost about ten pounds in the last six months.

The examination showed a normal heart and lungs. Abdomen was flaccid; there was slight tenderness over descending colon and sigmoid; and patient complained of occasional pain over splenic flexure. Digital examination revealed a protrusion into the rectum which felt like an os uteri, and was surrounded by sulcus. Proctoscopic examination showed hypertrophic catarrh of rectum; some mucus, and faecal matter; sigmoidal mucous membrane was congested; bled easily, and was covered by a mucus resembling the white of an egg.

Diagnosis: Prolapse of sigmoid.

CASE II.—E. F., twenty-four years, nurse.

Family history: Mother had typhoid fever several years ago, which was followed by colitis and constipation. Father died of pneumonia.

Personal history: Several years ago patient had cellulitis of the right leg; diphtheria; mastoiditis; and typhoid fever. She had suffered occasionally from muscular rheumatism, and had had a pain in the rectum and left side since she was thirteen years old. Pain was worse when she was constipated.

Present illness: About two years ago she had a severe diarrhoea which lasted four months; following this, she suffered from constipation up to the time she was operated upon for appendicitis; after this, her stools were fairly regular for a time. She suffered occasionally from diarrhoea; had had two attacks last week, and since then had been constipated. Had distress and eructations an hour and a half after eating. About once in one or two weeks she had attacks of severe gripping or twisting pains, which lasted anywhere from twelve to fourteen hours, and were followed by the passage of large quantities of mucus and membrane. She never had a satisfactory movement of the bowels; always the feeling of unfinished business; but was relieved when she took an enema.

Diagnosis: Extensive adhesions between omentum and caecum; the omentum was also adherent to the descending colon or sigmoid. Cystic ovary about the size of an egg adherent to the sigmoid, which was prolapsed. Mass could be felt through the anterior wall of the rectum.

CASE III.—Mrs. C., thirty-two years, widow, appearance healthy.

Family history: Patient had menstruated at the age of fifteen, and had always been regular. Was thirty years old when she gave birth to a child, and at that time was badly lacerated. It was necessary to perform upon her a perineorrhaphy and trachelorrhaphy. She had always had trouble with her bowels; gripping pains all her life; never, as long as she could remember, had she had a satisfactory movement; troubled with gas and cramps in the lower part of the abdomen and a feeling as though there were a lump

in the rectum. Since her child was born all her trouble had increased, and she had a feeling of heat across the lower part of the abdomen, and a dull aching pain in the back. When walking or going up stairs she had a pain in the left inguinal region. Had flashes of different colors before the eyes; and had a feeling as if the top of her head were being lifted off. Soreness all over the abdomen. About two hours after eating, had acid eructations, sometimes very bitter. She suffered from nausea, and vomited occasionally. Had a floating kidney on the right side, and movable on the left. Had about three movements daily.

Diagnosis: Prolapse of the sigmoid.

36 WEST THIRTY-FIFTH STREET.

### OSTEOMYELITIS.\*

By FRED H. ALBEE, M. D.,  
New York,

Assistant in Orthopaedic Surgery, College of Physicians and Surgeons (Columbia University); Instructor in Orthopaedic Surgery, Postgraduate Medical School and Hospital; Clinical Assistant, Hospital for the Ruptured and Crippled.

Acute infectious osteomyelitis is a pyogenic infection of bone, occurring most frequently in early life. Trendelenburg, from an analysis of 1,058 cases at Brun's clinic, states that it is most common from the thirteenth to the seventeenth year. In one half the cases the femur was involved, in one third the tibia. Others state that 50 per cent. of cases occur during these years. It is due generally to the *Staphylococcus aureus*. However, other organisms, such as streptococci, pneumococci, and typhoid bacilli, are sometimes the cause. Certain factors also predispose to this disease, such as exposure to cold, trauma, fatigue, acute infectious diseases, and typhoid fever.

In most cases complicating the infectious diseases, it is a secondary infection, but occasionally it is said to be primary, as typhoid osteomyelitis. In a certain number of fractures the ends of the bones become infected and a traumatic variety results. Here the process is almost invariably confined to the immediate locality of the fracture.

The usual location of acute osteomyelitis is either at a point of injury or in the extremities of shafts of long bones, near the epiphyseal cartilage, and beyond which line it rarely extends because of the marked resistance cartilage bears to infection and the different blood supply of the epiphysis. In some cases, especially in adults, in whom the epiphyseal cartilage has ossified and no longer persists as a bearer, the infection may extend through the epiphyseal line and involve the epiphysis and joint. The beginning focus is always in the marrow, the trabeculae and cortex being attacked secondarily. Its location is an important point clinically, because tuberculosis practically always begins in the epiphysis. Now since the marrow cells communicate very freely with each other the toxic material, retained in this dense shell, spreads rapidly, and large areas may become necrosed before infiltration with exudate is even marked. The process may extend along these spaces and the entire marrow of the shaft be involved in a very short time. The extent to which cortical necrosis occurs depends upon two things. On the extent of destruction of the endosteum and the amount of separation of the periosteum (Nichols). Since these two factors vary

greatly in individuals, it is easily understood that the amount of necrosis of the cortex must vary within wide limits. If the endosteum remains viable, the internal layer of the cortical bone will retain its vitality. If the periosteum is intact, the

outer layer retains its vitality. The marrow has considerable power of repair. Dense cortical bone has practically no reparative power.

The overlying soft tissues, in some cases, may

\*Read before the West Side Clinical Society, March 20, 1918.

come infiltrated, and in certain instances an abscess connecting with the bony focus forms. The periosteum is often separated from the cortex and elevated from the bone over a large area. In this event the space is filled with a purulent exudate. Finally such an abscess may perforate the skin through one or more openings, leaving sinuses which lead down to bare necrotic bone.

*Symptoms.*—The disease commonly begins with a sharp onset and the symptoms are definitely localized pain and sensitiveness, as well as all the constitutional symptoms of an acute infection, with the absorption of infectious material. The temperature is usually elevated to about  $103^{\circ}$  to  $104^{\circ}$  F. and the pulse is usually greatly accelerated. The tongue is dry and coated. The face is often drawn and flushed. The leucocyte count is usually very high—

FIG. 2.—Localized osteomyelitis of the great trochanter. The symptoms in this case simulated very closely those of tuberculosis of the hip joint. After the removal of the sequestrum, which appears in the skiagraph, the convalescence was rapid.

20,000 or 30,000. The course of the disease varies with the virulence of the organism and the extent and the situation of the process. The pain is usually intense, and if the bone is superficial, swelling can usually be detected early. The skin may become red or livid. In a few days either pitting on pressure or fluctuation appears. When the bone is more deeply situated, or when the process has not extended beyond the medullary cavity the swelling and redness may not appear until late.

In young children, who are usually not apt to localize pain well, it may be only after very careful study that the particular bone affected is found, especially when the patient is in a state of stupor. However, pain is usually elicited by pressure over the focus or by jarring the sensitive bone, such as tapping on the foot in a case of involvement of the

tibia or femur. The diagnosis of early cases in older children is sometimes difficult even to experienced men who have the lesion in mind. The pain is frequently referred to a neighboring joint, in which no evidence of involvement can be made out, or the swelling of such a joint may come on so early as to distract attention from the disease in the bone until an abscess appears. In severe cases the symptoms may be very grave, and the patient may die in a few days of septicæmia, while in other instances the patient may survive the local disease, but subsequently die of pyæmia, ulcerative endocarditis, exhaustion, etc.

If suppurative arthritis occurs in the neighboring joint the case is a very grave one. The prognosis, however, depends to a great extent on early and vigorous treatment, so much so that even the gravest cases may be saved. Under any circumstances, the prognosis should be very guarded as to immediate and remote results, the certainty being that at best the illness will be long, and that the neighboring joint may be involved, or that a deficiency in growth, with its resulting deformity, may follow.

The diseases which are most liable to be confounded with this disease are tuberculous arthritis, gonorrhœal arthritis, typhoid fever, acute rheumatism, and abscess of soft parts. Tuberculosis of the joints nearly always begins in the epiphysis of the long bones, while osteomyelitis, as stated before, almost always begins in the diaphysis. In cases of epiphyseal osteomyelitis, the sudden onset, intense pain, early involvement of joint, marked leucocytosis, in contrast with its absence in tuberculosis, and the presence of constitutional symptoms, should allow a diagnosis.

Acute articular rheumatism generally affects more than one joint and the symptoms are much milder. The constitutional disturbance, the leucocyte count, and the temperature, are all very much less. The reaction to salicylates may help. The pain and symptoms in osteomyelitis are in the bone and not in the joint.

Gonorrhœal rheumatism may affect but one joint, and in some cases the early symptoms are severe. The history of a previous attack of gonorrhœa can usually be elicited and the bone tenderness is wanting. The constitutional symptoms are much less severe. The detection of gonococci in the joint fluid would be conclusive evidence.

The high leucocytosis, the pain and local symptoms, sudden onset, and absence of Widal reaction, usually permit a distinctive diagnosis from typhoid fever. Any severe pain in bone, with or without swelling, should always recall the possibility of acute osteomyelitis.

*Treatment.*—The treatment of acute osteomyelitis consists of two operative steps, the first for drainage, the second for removal of dead bone. The first operation consists in cutting down to and turning aside the periosteum, and then in trephining or chiselling away enough cortex to thoroughly expose the whole extent of the disease. In cases where the whole diaphysis is affected it may be preferable to make several openings in the bone and to scrape out as much of the medullary cavity as is filled with purulent material, between them, rather than to make one large gutter the whole length of

shaft. It is extremely desirable to leave all the marrow possible, even if it is somewhat infiltrated, because the curetting of the marrow causes a destruction and removal of the endosteum upon which the integrity of the internal layer of the cortex depends. As a large part of the bone will die anyway in the severe cases, there is no harm in removing a considerable amount of bone for thorough drainage.

The medullary cavity should then be carefully cleaned out with the curette as far as the diseased marrow extends, and the cavity sponged with crude carbolic acid, followed by alcohol. A large drainage tube with gauze packing about it should be then packed into the cavity thus left and the limb placed in a splint.

If, in exceptional cases, at the end of three or four days the process seems to have been well localized, the necrotic bone to have been entirely removed, and the wound appears aseptic, then the gauze and tubes may be left out and only one small drainage tube retained at the ends of the wound, which can be drawn together in its centre, or the bone cavity may be dried and filled with iodoform bone plugging material of the late Mosetig-Moorhof, of Vienna. This mixture consists of iodoform, 60 parts; spermaceti, 40 parts, and oil of sesame, 40 parts. This is heated until it becomes fluid, and is then poured into the bony cavity, which it hermetically seals by hardening at the body temperature. In this event the skin may be entirely closed by suture.

In rare instances, cases brought to the surgeon early may be operated on before the destruction of the endosteum or cortex takes place, and the marrow will regenerate from the endosteum. Complete regeneration of the bone will then take place, with no formation of a sequestrum, and the wound will heal by granulation.

Where joint symptoms do not subside after thorough drainage of the diseased bone, it is well to aspirate the joint for the purpose of a bacteriological examination. If infection is found, then the joint should be treated as a case of infectious arthritis, irrespective of the associated lesion.

In all instances where the whole or part of the diaphysis is dead and becomes separated at the epiphyseal line the operative treatment should be in two steps. First, continued thorough drainage should be maintained, after the operation described before, until the sequestrum separates well and the periosteum thickens about the dead diaphysis sufficiently (*i. e.*, to about one sixteenth to one tenth inch thick). This is the so called involucrum. The time required will be between eight and twelve weeks, providing an accessory bone is present which may act as a splint and maintain the length of the limb during the process of bone regeneration, *e. g.*, the fibula may act as a splint bone during the regeneration of the tibia. In cases where there is only one bone in a limb, as the humerus, in the arm, the danger of deformity from muscular contraction is great if the necrotic shaft is removed before the periosteum becomes rigid. However, if we wait too long the periosteal shell will begin to ossify and will have no power to proliferate cen-

trally and fill up the cavity left by the removal of the sequestrum. At the end of about fourteen weeks the involucrum, although it is quite rigid and capable of acting as a splint, still retains much of its power of central growth. At this time it is about one half the diameter of the normal humeral shaft.

The second part of the operative treatment consists in incising the involucrum both ways to the extreme ends of the sequestrum, in separating it by

FIG. 1. Incision extending along the middle line of the tibia in a child of seven years. The wound is closed in three days after the removal of the sequestrum.

blunt dissection from the underlying dead bone, and in shelling the latter out, as a banana from its peel. In order to do this, healthy bone, which may overlie the sequestrum, often has to be chiselled away before the dead bone can be reached or entirely removed. It is best to extract the sequestrum in toto if practical, thus insuring its entire removal.

In all instances the epiphyseal cartilage should be interfered with as little as possible. The gutter left should then be thoroughly scraped and cleaned, being ever mindful also not to injure the involucrum upon which we are so dependent for the new bone formation. The cavity may then be packed with gauze and drainage tubes as described before, or it may be filled with iodoform bone plugging material, and the skin brought together and sutured over it. The latter procedure is feasible only where the infection has well subsided.

In cases where a part only of the circumference of the cortex dies and the sequestrum lies deep,

FIG. 4. Specimens of osteomyelitis from the pathological museum of Columbia University. The bone to the left is a specimen of osteomyelitis of the lower end of the femur.

The sequestrum (b), three inches long, was never removed and the involucrum (c) formed about it; the bone to the right is a specimen of osteomyelitis of the lower end of the tibia (the bone is reversed); (c) holes in the involucrum which nature has left for the drainage of the sequestrum pocket beneath; (d) sequestrum (dead shaft) in situ; (e) involucrum.

and approximately one half of the healthy cortex remains viable, the involucrum with the attached skin and soft tissues may be turned into cavity and nailed to remaining plate of cortex with sterile tacks (Neuber). In this way the whole wound may be closed. This procedure is likewise possible in cases of mild infection, and only when it is fairly

certain that all infective material has been removed.

The limb should in all cases be firmly held either in a plaster of Paris splint with a large window for dressings, or by a wire splint. And, in either case, some splint should be retained until sufficient bone foundation has taken place to give a weight bearing stability. If bone in an adequate amount does not develop, bone grafting should be subsequently employed. However, it should be understood that it may require many months for complete ossification to take place.

In a recent case where two thirds of the lower part of the tibia was removed by the writer, it was fourteen months before the brace could be discarded. The appearance of osteoid tissue of about the consistency of an early external fracture callus is usually rapid, but its transformation into bone is much slower.

In addition to the acute forms of inflammation of bone there exists a more chronic type which is more apt to be multiple in its manifestations. The amount of bone involved is often very extensive, and therefore furnishes very difficult operative problems. The sequestra lie in large bone cavities whose walls are very dense. If the process is of very long duration the periosteum will be much thickened. Fortunately this type of case often quiets down from careful rest, hygienic, and brace treatment. The operative indications are the same as those of the more acute variety.

A third type is a definitely circumscribed process to which the names of bone furuncle or Brodie's abscess have been applied. The pyogenic cocci are usually the infective agent. It is occasionally chronic in its course, and gives little clinical evidence of its presence. Frequently the process is located near a joint or even at the epiphyseal cartilage and is thus liable to be confounded with joint disease. Its thickened wall stands out very distinctly in the radiograph.

The operative principles laid down before are of equal importance here. The curette should never be used as a subterranean instrument for scraping blindly about either in this condition or in that of old bone sinuses, but should always be used under the direction of the eyesight. This is an important precept and one that is often violated, which is, I am led to believe, one of the reasons for the existence of many persistent osteomyelitic sinuses.

The operative indications are to remove the dead bone which is likely to lie beneath newly formed periosteal bone, through which a hole always persists for the drainage of the sequestrum pocket beneath. Now in order to get a thorough exposure of the sequestrum, it is often necessary to make a considerable skin incision and remove with chisel and mallet a considerable amount of overlying bone, either old or newly formed. This new bone forms very rapidly on account of the irritative stimulation of the periosteum by the presence of the dead bone. If possible the sequestrum should be removed in toto. When all particles of dead bone are removed the sinus will immediately close and close permanently, providing sufficient endosteum remains intact.

## A SIMPLE "AIR HOUSE."

By J. T. TUBBY, JR.,  
New York.

The question of open air bungalows and sleeping quarters is no longer restricted to building for tuberculous persons. It is admitted that sleeping out of doors is as beneficial for the so called "well" as for the sick. Hence the prediction is well founded that the community will shortly demand of its architects first, the design of second story loggias, then of temporary free standing bungalows, and finally open buildings of a type to supply an abundance of fresh air under the least artificial conditions. Already the

It is desirable to select a dry, well drained site for the structure, in a position having a free circulation of air. It may stand alone or in juxtaposition to a sheltering house. Connection to a house piazza is a convenient arrangement. A site well shaded with tall trees trimmed up to ten or twelve feet from the ground would be excellent.

The air house shown in the accompanying sketch has a room about eight feet by thirteen feet, with an ample porch. The roof has a wide overhang at every point.

The house is raised three feet from the ground upon three inch locust, cedar, or chestnut posts set three feet into the ground. Sills and beams are of

FIG. 1.—"AIR HOUSE."

evidence pointing to such a conclusion is strong. Our architectural periodicals show in greater numbers designs for cottages of very open type.

In the present state of popular opinion, from the point of view of that same being, "the average man," the question of the use of outdoor sleeping quarters is considered a question of luxury. Such need not be the case. Sleeping quarters of the type treated in this article can be built inexpensively and can be used to advantage as additional veranda space or for a children's playroom in the daytime.

hemlock, spruce, or pine. The flooring is made of one inch at centre to throw out water. The window openings, and, in fact, the whole house wall above three feet six inches is closed with shutters of roofing paper, waterproofed canvas, or some similar material, stretched over a light wooden framework. The shutters are manipulated precisely like an ordinary window sash and allow the closing of the entire structure or the opening of any part of it to the window sill level. Wire netting may be tacked out on outside lacing in a manner suggested by the

quitos. Light is afforded, in the rare case of closing the shutters, by two window sashes in rear wall and two sashes in the front doors.

The color treatment should harmonize with existing conditions of site. The temperature inside, however, is affected by a light outside color. Dull colors for interior finish and underside of eaves will prove restful.

The furnishing will be dictated by the taste or convenience of the occupant.

The cost of such a structure will depend on the cost of lumber and of labor at the place of erection.

subject to eyestrain. In the discussion which followed, Patrick, of Chicago, voiced the prevailing opinion among neurologists when he said that he referred such patients to a competent oculist as a matter of routine, unless they had already consulted one, but that the cases in which migraine had been cured were of extreme rarity in his experience. Some neurologists go even further and consider the connection between eyestrain and migraine to be so improbable that it is a waste of time to have the eyes examined at all in such cases, while some ophthalmologists go to the other extreme and state that

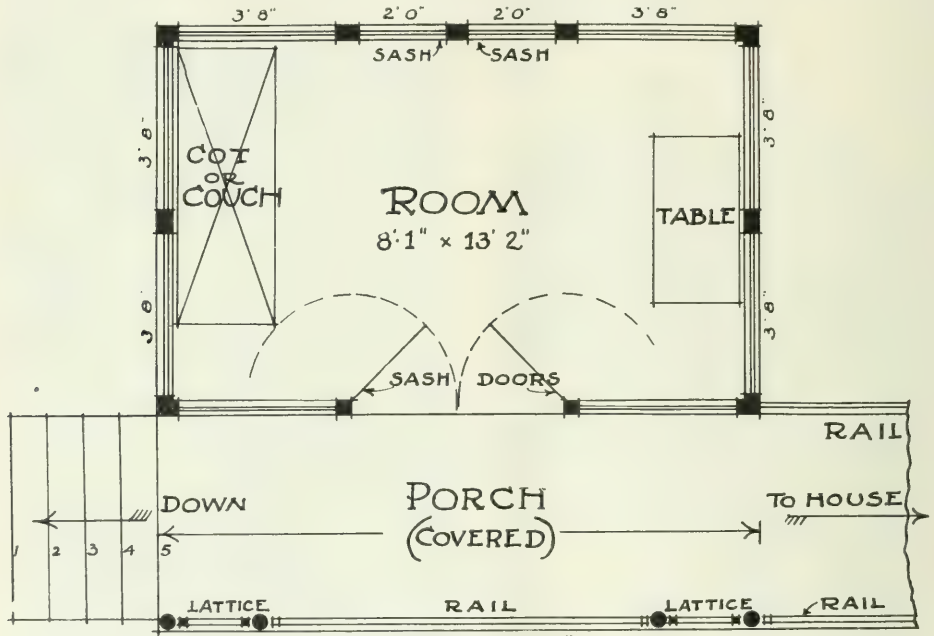

FIG. 2.—Plan of "Air House."

In the neighborhood of New York it could be built for about \$150.

If a dozen or more of uniform design were erected for sanatorium use, etc., the individual cost would be materially decreased.

81 FULTON STREET.

#### TO WHAT EXTENT IS MIGRAINE AMENABLE TO TREATMENT OF THE EYES?

BY ELLICE M. ALGER, M. D.,  
New York.

At the last meeting of the American Medical Association Coggeshall and McCoy, of Boston, presented to the neurological section a singularly conservative and temperate joint paper on headache, which they concluded with the broad statement that their experience had led them to consider the variety known as migraine or sick headache in the great majority of cases as the reaction of a neurotic

they are able to cure practically every case under their care.

Like most disputes between honest men the present one probably depends in large part on lack of understanding to start with, first as to what constitutes competent eye treatment; second, what is to be considered a cure, and, finally, most important of all, exactly what is meant by the term migraine.

Coggeshall and McCoy have given in the paper referred to a definition of what they understand by competent eye treatment, and conclude: "We venture to say that most neurologists who are sceptical about the eyes as a factor in migraine and other less severe forms of headache have failed to give this much consideration to the details of the oculist's treatment, but if we do not pay unremitting and exact attention to all these minutiae we shall continue to see cases of migraine that are not due to the eyes." Most men place their confidence in a competent oculist, which is not the same by any means. Just as a man may be a perfectly competent general surgeon

and yet do the most ragged kind of special surgery, so there is a vast number of oculists skilful and generally competent, but who lack the interest or the time or even the skill to do good refraction-work.

I will not enter into a discussion of methods, the use of cycloplegics, the value of the ophthalmometer, the investigation of muscular imbalances, and other questions over which oculists are divided, but it seems only reasonable to argue that competent treatment means treatment by some one who habitually gets results at least approximating the most successful by whatever methods of work he deems most suitable in a given case. Judged by this standard, many oculists cannot be considered competent when it comes to the treatment of migraine and many other nervous affections, which, it is admitted, they seldom treat successfully.

The term "cure" also needs explanation. Even supposing for the moment that eyestrain is admitted as the chief exciting cause, every migraine patient also has an underlying nerve instability often hereditary, without which no amount of excitation would be effective in producing an attack. This instability may be so great that even overuse of normal eyes is disastrous, or, on the other hand, the irritability may be slight while the exciting eyestrain is relatively large. The first case we should hardly expect to benefit short of stopping entirely the use of the eyes, while the second would cease to have trouble as soon as we have enabled him to use his eyes economically. The majority of cases fall between these extremes, but it seems to me that we are hardly justified in using the word "cure." We do indeed often remove the exciting cause and the attacks cease, but the underlying instability is still present, perhaps modified to some extent, but still capable of reacting to a sufficient excitation.

Then, too, we are not all agreed as to just what the term "migraine" means. Many general practitioners and not a few oculists base their diagnosis on the severity of the attack and consider every violent headache as a migraine, especially if it is one sided, and, on the other hand, overlook many typical cases in which the head symptoms are not very severe. Migraine is defined in the textbooks as an explosive paroxysmal psychoneurosis developing in certain neurotic individuals. It is in a sense a family disease, being often traceable in the direct line for generations. Patients may be unaware of this, but questioning will often elicit a history which is suspicious, to say the least, of "sick headache," "bilious headache," "neuralgic headache," in various ancestors. In the same families this nerve instability is sometimes evidenced by cases of insanity and epilepsy, and indeed between the latter and migraine there are so many analogies that many authorities consider the one a sensory form of the other. A long list of exciting causes is usually given, which may precipitate at attack from time to time, such as lowered health, constipation, auto-toxæmia, gout, fatigue, worry, and strong emotions. A few years ago none of the textbooks mentioned the abuse of the eyes as an exciting cause. Recent editions are now almost unanimous in putting it among the possibilities, and we may hope that in course of time it may be included in the long list of probabilities.

The symptoms in a typical case are unmistak-

able, consisting of an aura, followed by sensory disturbances generally involving the eyes, headache, nausea and vomiting, and, finally, by sleep which precedes recovery. But not one of these symptoms taken singly is pathognomonic, so that in atypical cases it is often difficult to establish the diagnosis beyond cavil. The premonitory symptoms, for instance, are often wanting. They often consist of a feeling of dulness and apathy, or possibly of unusual exhilaration, which in this individual leads him to expect an attack, but they are not in any sense diagnostic, and are not invariably followed by migraine. The sensory phenomena are the most constant and characteristic, and are usually confined to the eyes. They often consist of sparkling lights, near the fixation point, which widen and assume the most changing and fantastic shapes, and at the same time there is disturbance of vision, varying from photophobia to absolute blindness of corresponding halves of each retina. The headache comes on at once, sometimes one sided, but not always so by any means. In some patients it is regularly very slight, and is not allowed to interfere with usual duties, but in others it is an excruciating jumping pain, which lasts perhaps several days and causes utter prostration. In most cases there follows an intense nausea, often accompanied by vomiting. There is a complete arrest of digestion, but the vomiting persists long after the stomach is empty, and only serves to increase the headache.

These are so often associated in the minds of both patient and physician that the indigestion is considered the exciting cause of the attack, which is spoken of as a bilious headache. But there are many cases in which the nausea is hardly noticeable, and the vomiting does not occur at all. It is a notable fact that for a variable time after an attack the usual exciting cause seems incapable of precipitating another attack.

Recent authorities are beginning to agree that faulty eyes may be a factor in migraine, but there are many reasons which suggest a far closer connection than is generally admitted. For instance, migraine begins in thirty per cent. of the cases between the ages of five and ten years, or just at the period when school life is beginning to put the first serious strain on the eyes. Of the balance most begin in the second decade, and only in the rarest instances does it begin after thirty. It is said to gradually subside after the menopause, and this has been considered significant, but it must be remembered that it also begins to abate in men at the same age. But this same period in both sexes marks the onset of that great change in the eyes which we call presbyopia, during which the patient is gradually compelled to admit that even straining his eyes no longer results in satisfactory near vision and that glasses have at last become a necessity. But among those who deny the presbyopia and put off as long as possible the wearing of glasses, attacks of migraine are notably increased both in frequency and severity. In old age, when the accommodative power has practically disappeared, attacks practically never occur. The very fact that the individual symptoms of migraine often appear in other patients as the result of abuse of the eyes is suggestive. In many cases patients have noticed

that attacks are much more frequent when they are doing work that involves unusual use of the eyes, while conversely when leading an outdoor life they are practically free. Careful questioning will elicit the same history in many others.

There are three ocular conditions which are conceivably concerned in attacks of migraine. First and most important, over use of the ciliary muscle in accommodation, which may exceptionally occur in normal eyes by reason of immoderate use, but is almost invariable in hyperopia and especially in astigmatism, since it is only by accommodation that clear vision is secured; second come conditions in which binocular vision is impossible without undue strain of the extrinsic ocular muscles; and, third, the cerebral fatigue that comes from the constant interpretation of distorted or unequal retinal images, as in astigmatism and anisometropia. It can readily be seen that the relief of these conditions may often be a very complicated problem, an exact solution of which is sometimes impossible. In most people Nature herself has compensatory powers, and if we can bring the error within the limits of those powers we shall have given all the relief necessary. This is the reason why inexpert work is so often perfectly satisfactory to patients in ordinary conditions. But it must be remembered that in migraine and many other nervous conditions it is this very attempt at compensation that causes the trouble, and a much closer correction is called for.

The one great defect in the evidence is the widespread failure of ocular therapeutics to afford relief, even when applied by men whose reputations are of the highest. This may be due to two causes, first, that the ocular treatment is seldom as patient and painstaking as it should be; and, second, because there may be cases in which eyestrain is not the chief cause and perhaps not a cause at all. So far as my own experience goes, I believe both to be true. Many of the patients whose histories are here recorded had received from reputable men prescriptions very different from the ones which finally proved beneficial. On the other hand, there are many patients whose hereditary instability is so great that an explosion may occur from any one of several exciting causes. Suitable eye treatment might prevent some of these attacks, but could not possibly prevent them all. Other cases are pure eyestrain cases, and are completely relieved.

I believe a thorough examination of the eyes should be made in every case, not only once, but several times, by different men if the first is not successful. This may seem an extreme position to take, but when one considers the alternative plan of treatment as outlined in our standard textbooks: the long continued use of drugs, ranging from bromides to cannabis indica, with analgesics for the attack ranging from acetanilid to morphine, very possibly combined with a rigid diet, intestinal antiseptics, and continued abstinence from nearly every interest or occupation that makes life worth living to a normal man or woman, and when, after all this, we are obliged to tell our patient that these measures are only occasionally productive of permanent good, but that, at the very worst, his old age will be a happy one, the ophthalmological position does not seem so extreme.

Many oculists have recorded their success in the relief of migraine, but the term is used so indiscriminately that I have thought it wise to append the histories of a few illustrative cases, which, it will be noted, were not all successfully treated. Some of them seem from the very history to be pure eyestrain cases, and were invariably relieved. In others, notably Case X, the nerve instability is the predominant factor, while still others occupy an intermediate ground. One or two of them date back to a time when I thought I could do sufficiently accurate work without a cycloplegic, a practice which I have given up in all cases of any moment. I am sure it was the cause of my being compelled to write "benefited" instead of "cured" at the end of many a case record.

CASE I.—Male, aged twenty-eight, bookkeeper. Family history not noted. For several years he had had attacks of migraine at frequent intervals which he had supposed were due to indigestion and for which he had had much treatment by various physicians without any result. For some time past he had been having an attack every other day, generally in the afternoon, beginning with scotoma scintillans, followed by nausea and vomiting, the whole lasting a couple of hours. He had noticed that he rarely or never had an attack while on vacation. He had never had any trouble with his eyes, and only came to satisfy the wish of his physician. His static refraction was R. E. + 62 + 37 ax. 105; L. E. + 75 + 50 ax. 105. A month later he complained that his glasses fogged things except when he looked straight at them, but that he had had absolutely no headache, though there had been no change in the kind or condition of his work. This has continued since.

CASE II.—Female, aged twenty-two, housewife. Patient could remember that her mother had frequent severe headaches sometimes lasting several days, but could recall no details. She herself as a schoolgirl had severe headaches with nausea, which were ascribed to biliousness. These became less frequent after she finished school, but during the last five years recurred every two or three weeks, being so dependent on the use of her eyes that she had to give up reading and sewing to a great extent. They generally began with a "flimmering of light," followed by hemianopsia and a headache which was usually onesided at first. She has no nausea now, but used to have. The duration of an attack was about twelve hours. Her static refraction was R. E. + 1.75 + 25 ax. 120; L. E. + 1.50 + 25 ax. 60. A month later she reported that she had been reading all she wished and doing much of the sewing for four children, and had had no headache of any kind except one night at the theatre, when she had left her glasses at home. Up to the present time, a period of five months, the same freedom from migraine has persisted.

CASE III.—Female, aged twenty-nine, occupation housewife. Family history negative, did not suffer from school headaches and remembered no abnormality as a girl. At age of twenty-two began to have attacks of migraine, especially at menstrual periods and when subjected to excitement. Married at twenty-six, no children. A year ago lost her husband, since when she had been having attacks much more often, every week or so. The attacks began with a heavy feeling, followed by "white specks" before the eyes and a severe frontal headache, getting worse till she went to bed. She had nausea and sometimes vomiting, which last afforded some relief. Otherwise she was perfectly well and had never been conscious of any eye trouble. Her refraction under atropine was R. E. — 1. — 4.50 ax. 15 = 20/50; L. E. — 5.25 = 20/30. She had a divergent squint in relaxation, Maddox rod showing an exophoria of 10° with a left hyperphoria of 4°. I supposed this would have to be corrected, but she reported three weeks later that at her menstrual period she had had no headache for the first time in years, and this has been the case to the time of writing, a period of five months, so that I have thought it advisable to let well enough alone.

CASE IV.—School girl, aged fourteen. Family history negative. Patient had had no serious illnesses, but was rather anæmic and delicate. She was of a nervous temperament, and had been subject to headaches for several years.

sometimes having them several times a week, especially in school time. Frequently, but not always, they were preceded by flashes of light and followed by nausea. She first noticed failing vision about two years ago, and a glass of No. — I. D. was prescribed by a well known oculist. This had no appreciable effect on her headaches, and she thought her eyes were getting worse all the time. Her refraction under atropine was at this time R. E. — 1.25 — 75 ax. 105; L. E. — 1.25 — 75 ax. 75. The corneal radius was 7.05. Eighteen months later she reported that she did not remember having any headaches. Under homatropine she required a half diopter increase in the sphere to give her normal vision.

CASE V.—Female, aged twenty-two, occupation machine operator. Family history not noted. Patient had always been nervous and as a schoolgirl was of the opinion that she had headaches nearly every day. She was otherwise healthy and never had her eyes examined till four years ago, when an optician prescribed some concave cylinders, though she had never been near sighted. These glasses helped her only for a short time, but had been worn steadily even since, though the headaches were now typical migraine attacks, occurring about once a week and followed by nausea and vomiting. Her eyes called for a convex cylinder instead of a concave, her refraction being R. E. + 75 ax. 45; L. E. + 1.25 ax. 135. A month later she complained that she had had a hard time in getting used to her glasses but had had no headaches. I have not seen her since, but in writing for a copy of her prescription, two years later, she reported that her glasses were all right and that she was having no trouble.

CASE VI.—Female, aged thirty-one, housewife. Very fond of sewing and embroidering. Family history negative. Always healthy except for two attacks of rheumatism, which had left a heart complication. Married eight years without children, and was said to have a retroversion. She was of a nervous temperament, but was not hysterical. Her eyes had troubled her all her life, being, as she said, "near sighted." She received glasses from an optician in childhood which improved her vision, and she did not remember being troubled with headaches while in school. During the last year or so had been having many headaches which she thought depended almost entirely on the use of her eyes, as she was almost entirely free in the summer, when she was out of doors most of the time. Her eyes became tired, her sight blurred, and shortly she had a severe headache, generally right sided, which was soon followed by nausea and vomiting. A year ago she was examined under atropine by one of our most experienced oculists, who prescribed R. E. + 2.25 ax. 75; L. E. + 2.25 ax. 105. These gave her no appreciable relief and, indeed, in her opinion, were not as helpful as the previous glasses by the optician. Her true correction was R. E. + 3 + 150 ax. 120; L. E. + 250 + 150 ax. 60. Her husband reported four months later: "Glasses thoroughly satisfactory; can read and sew a great deal, and has not been troubled with headaches, though she is obliged to wear her glasses constantly. She cannot work comfortably by lamplight." Two months more have now elapsed without an attack of migraine.

CASE VII.—Male, aged thirty-four, occupation business man. Father and grandfather had typical migraine. Patient had headaches all his life, beginning with luminous flashes and settling in left eye. Nausea and vomiting not invariable. Had been free at times for three weeks, and once had no attack for six months while taking what he thought was strychnine. Thought he would have attacks several times a week, but took acatinal in 10 grain doses when he felt them coming and often aborted them. Attacks sometimes lasted for several days and even a week. His occupation at times placed great strain on his eyes and he had always been a very heavy smoker. Otherwise he was healthy and did an unusual amount of work. Declined to have a cycloplegic examination at present. His refraction without cycloplegia was R. E. + 75; L. E. + 75. I am certain that this was not by any means his full correction, but he complained constantly that his distant vision was fogged, though it made his near work much easier. A month later he reported that his headaches had been both fewer and milder, but complained so much of the fogging that I reduced the strength of his glass a half diopter. A month later he reported headaches were not and went back to stronger glass. The next month "was threat-

ened with headache many times but had only one," which he thought was due to something he ate, as it was accompanied by gastroenteritis. He had stopped the use of tobacco. Nine months after his first visit he reported that he had been entirely free from headache till recently he had to do "over 100 columns of fractional figuring" and had had trouble ever since. He had begun smoking again.

CASE VIII.—Male, aged thirty-six, minister, who did much literary work. The family history was negative. As a child he was delicate and had frequent sick headaches characterized by "quivering of the eyes," severe headache and vomiting. Could remember rolling on the floor in his attacks, which lasted usually half a day. He was cured for ten years by an irregular nerve doctor, who gave him a syrup which tasted like peach pits. As sophomore in college had scarlatina, which was followed by migraine, often twice a week. This had continued more or less ever since, the headaches being much more frequent when he was studying and writing steadily. Had always been near-sighted and worn glasses, sometimes ordered by opticians and sometimes by physicians. They never had any effect on his migraine, the last by a well known oculist being R. E. — 1.75 — 50 ax. 180; L. E. — 1 — 50 ax. 180. Vision is equally good in both eyes, but he had a divergent squint with a left hyperphoria which was alternating. His refraction under atropine was R. E. — 1.50 — 50 ax. 45 = 20/20; L. E. — 1.75 — 50 ax. 105 = 20/20, which was very different from the preceding correction. Nothing was done about his squint, as it was not a cosmetic defect and he had learned to suppress the image in the nonfixing eye. He reported a month later that he had been able to use his eyes more comfortably than he could remember and had not had a suspicion of a headache. An interesting feature of this case was a habit of tilting his head to the right, presumably due to the oblique axis of his astigmatism.

CASE IX.—Female, aged thirty-five, occupied chiefly in looking after her health. Family history negative. Was brought up by an ambitious aunt who pushed her education. Between the ages of six and seven she began to have headaches so severe and frequent that she was allowed to give up study and run wild. Found she could wear her mother's glasses but was seldom allowed, for fear of injuring her eyes with such strong glasses. Never had a pair of her own till fifteen, since which time they have been changed often, always by opticians, except the last pair by an oculist (3.25), with a stronger pair for near work. She had had five children in the last eight years, was greatly run down, and had come north to recuperate. A well known internist said she had a mild anemia with entropion, but was otherwise sound. He advised iron and tonics with rest. An equally well known neurologist said it was a pure neurosis and advised bromides and no tonics. Just which plan the family physician adopted I do not know. The patient appeared a nervous wreck, was irritated by everything; was very hysterical at times and again was very melancholic. She was in great fear of death and complained of a band sensation about her head. Her digestion was bad, her heart irregular, and she was often troubled with insomnia. She said her headaches were often preceded by muscae volitantes and characterized by a "fireball" and one sided blindness. The right lid drooped and the right eye diverged slightly. Under atropine her correction was R. E. + 5 + 50 ax. 105; L. E. + 5 + 50 ax. 75. Both before and after atropine she had a marked cross diplopia with a red glass. Two weeks later I increased the strength of her glass a diopter for near work as her accommodation was subnormal, a condition which was in my experience very common in patients of Spanish descent. Four months later she was very much better in every way; had no more need for a nurse; had had little or no headache and very infrequent attacks of anxiety and depression. She had been doing a great deal of continuous shopping without undue fatigue and could use her eyes for reading and sewing with comfort for the first time in years. The dropping of the lid and the cross diplopia had disappeared, though she still had some muscae volitantes. Her eyes were so good that the entire improvement was due to the effect of the eye-glasses, but the last improvement was completely suppressed promptly from the time of the first installation of atropine. She has now returned to her home, but has not had a headache since that her condition remains unimpaired after a year of this month.

CASE X.—Mr. S. aged thirty-one, single, contractor.

There was a history of typical migraine on his mother's side for two generations. Patient was undersized, badly developed, anæmic, and of a decidedly neurotic type. He had never been very strong nor suffered from any severe illness. He had had attacks of migraine on the average once a month ever since he could remember, though sometimes they were more frequent. They often began with a capricious appetite or a mental exhilaration, followed shortly by scotoma scintillans and then a violent pain, beginning in one eye and finally spreading over the whole side of the head, with the most distressing nausea and vomiting. Sometimes the attacks lasted only twenty-four hours, but often the pain after leaving one side went over to the other, and such attacks sometimes lasted three or four days, during which he was absolutely confined to his bed. Coal tar products were of no use, but occasionally an attack could be aborted by a half grain of morphine hypodermically. The pain was so severe that it could be controlled by nothing but morphine, and I was frequently obliged to give him a grain a day without by any means affording complete relief. He was my *bête noir* for several years. The exciting cause of his attacks seemed numerous; one could be confidently expected after any worry or business misfortune, of which he suffered many, and sometimes they seemed to follow dining out and sometimes overuse of his eyes. I once apparently caused an attack shortly after a severe one which should have conferred temporary immunity by testing his eyes with prisms in my office. One attack I succeeded in aborting by instillation of homatropine after it was fairly started, but this invariably failed in subsequent attacks. His static refraction was R. E. + 75 + 175 ax. 90; L. E. + 75 + 175 ax. 90, with the addition of a + 1, sphere for near work. He regularly had an esophoria of about 2° between the attacks, but which increased during them so that he often had a perceptible squint with diplopia. In other words, he was affected with a spasm of the interni, which might have been either the cause or the effect of his attack. A full correction of his refraction apparently modified somewhat both the frequency and severity of his attacks during several months. He then had an operation on first one externus and then the other, which finally secured a normal balance of the extrinsic muscles, both as measured by the tropometer and prisms. This resulted in complete freedom for three months. About this time he failed completely in business and took a position as a clerk, and whether from the worry or increased work the attacks recurred. At first, however, they were notably less severe, as he was able to keep at his desk and do without any morphine at all. Eventually, however, they became about as severe as when I first saw him. During a period of employment in Philadelphia he had his glasses reduced slightly in strength, and since then I have no record of his eye condition. That winter he spent as a clerk in a country store, absolutely free from all worry and overwork, and the next summer as watchman in a summer hotel, leading an outdoor life, but under such conditions he said the migraine remained as when I first saw him.

55 EAST FIFTY-SIXTH STREET.

#### EPILEPSY.\*

##### *The So Called Idiopathic Form.*

BY BEVERLEY R. TUCKER, M. D.,  
Richmond, Va.,

LECTURE IN NEUROLOGY AND MENTAL DISEASES, MEDICAL COLLEGE OF VIRGINIA.

In presenting a paper upon so complex a disease as epilepsy I realize the limitation of the time allotted me and hence I shall only attempt to briefly condense what I consider most important. The Jacksonian type of the disease will not be considered, but only the so called idiopathic form.

Epilepsy is one of the most interesting, most distressing, and, until recently, most neglected of diseases. It has been known from time immemorial.

It affects every race, is found in every clime, and no age nor state of society is immune to this disease. Attacking its victim at the most unexpected moment, sometimes with and sometimes without warning, it has led to many unfortunate accidents, and is a constant source of danger to the patient and of extreme anxiety to the family and friends. It is a spectre that cannot be hid in the family closet, and its convulsions are only too often food for the morbid amusement of the curious and jeering inhuman element of human society. The jails and insane asylums can testify to the extreme effects of epilepsy; but the outlook is brighter now, for, in the last decade or two, the epileptic colonies are humanely and scientifically looking after many of these unfortunates. Our chief aim, however, should be to check the process before its ravages make institutional care taking necessary, and I shall attempt to show that with patience, knowledge, and proper management the disease can be frequently arrested and often cured.

The derivation of the name epilepsy implies "being seized upon." It has been called "falling sickness." Many superstitions have been connected with the disease and its victims have been considered as possessed with devils, or, on the other hand, it has been considered a sacred disease, morbus sacer, and more recently its manifestations have been thought to be due to an explosion of some sort of an electrical force. Some of the world's greatest men are said to have been epileptics, notably, Julius Cæsar and Napoleon. Some of the most vicious criminals and most profound idiots have also been epileptics.

Hippocrates and Lucretius have well described the convulsions, and from their time to nearly the nineteenth century the study of the disease has consisted almost entirely in simply noting the fit.

It is said that there is a fraction more than one epileptic to every four hundred of the population of this country. The probability is, however, that the proportion is even greater, as many cases, especially of petit mal, would not be reported for statistics. Sex has no marked influence upon the ætiology. The most frequent age of onset of the disease is the first year of life, about ten per cent. beginning at this time. Between eleven and twenty years about 46.5 per cent. begin, according to Turner. From twenty years on as age advances the frequency of the onset of epilepsy decreases.

Race has but little influence, except that it is rather rare in the negro. The hereditary factor has been the subject of much discussion, and statistics vary according to what the observer thinks heredity should embrace. In cases beginning early in life its influence is traced more frequently than in those beginning late. Epilepsy, alcoholism, and insanity are the chief hereditary factors. After reviewing a large number of statistics I conclude that these cannot be traced in more than forty per cent. of the cases. We must also bear in mind that many other individuals would present family histories of one or more of these diseases.

Intrauterine developmental conditions as malformations, hydrocephalus, and microcephalus, or birth trauma causing intracranial cysts, local compressions, or hemiplegias are sometimes seen, while

\*Read before the Executive Medical Association, at Charlotte, N. C., February 29, 1908.

rickets, scurvy, malnutrition, and other conditions infrequently seem to have some causative relation to idiopathic epilepsy.

After considering all of these there is still a larger class in which no clinically demonstrable cause can be elicited, but I purpose to point out later on that there is enough evidence in the latest pathological investigations to make us believe that every case of epilepsy has a definite histological and pathological basis. I believe I am justified in saying that the immediate cause of a convulsion or a series of convulsions has but little to do with the cause of the disease; that the convulsion is simply a manifestation of an underlying pathological condition; and that autointoxication and reflex irritations bear the relation of exciting causes only. These exciting causes may be shock, excitement, fear, overeating, improper diet, too violent exercise, mental and physical, overheating, masturbation, alcohol, reflex states from trauma, defective eyesight, adherent prepuce, ovarian or uterine disease, menstruation, pharyngitis or any irritative condition.

There are many clinical forms and types of epilepsy which must be distinguished and separately considered and treated if we hope to cope scientifically or successfully with the disease. The following classification is a modification from that of several authorities, especially Turner:

1. *Petit mal.* a. *Complete attacks*, usually without aura or marked convulsions, and with brief loss of consciousness. b. *Incomplete attacks*, consisting of aura only or brief periods of distracted attention without loss of consciousness.

2. *Grand mal.* a. *Complete attacks* with or without aura. Consciousness is lost and the patient may fall. Then there is a stage of tonic, then clonic muscular spasm which is followed by a period of more or less stupor. b. *Incomplete attacks*, consisting of aura, slight muscular paroxysm, and with or without loss of consciousness.

3. *The combined type*, consisting of sometimes major and sometimes minor seizures.

4. *Nocturnal.* a. Either major or minor attacks occurring only during sleep or in the predormant or postdormant stage. b. Mixed day and night attacks.

5. *Serial.* Attacks, either major or minor, occurring in a series of fits with periods of freedom or comparative freedom.

6. *Status epilepticus*, major or minor fits with one attack following another so closely that consciousness is hardly regained, or not regained, between the convulsions.

7. *Psychical epileptic equivalents*, which, if we follow Turner rather closely, consist of: a. *True psychical epilepsy*, as automatic movements, like undressing without realizing it, etc. b. *Epileptic ambulatory automatism*, in which, sometimes for days, a patient may travel and then suddenly find himself in a strange community without knowing how he got there. c. *Epileptic mania*, including impulsions. d. *Dream states*, consisting of a feeling of non-existence and doubts as to reality of surrounding things. These feelings recur at intervals and may be preceded by an aura. e. *Transitory delusional states* in which the patient may be pugnacious and hard to manage. f. *Catatonic stuporous conditions*.

These also occur in nonepileptic patients and are usually marked by a blank expression and rigidity. g. *Cephalic sensations* occurring in epileptics which seem to replace the seizure. Headache is an example when it takes the place of an attack. h. *Aura*. This is present in about half the cases and may occur without the convulsion following. This aura, or warning, may have a motor manifestation, as localized muscle spasm, or a sensory, as a sick sensation in the stomach, or may be purely psychical, as fear. I have a patient who has aura of all three varieties. i. *Miscellaneous equivalents*, as narcolepsy, paroxysmal laughter, or sneezing, which, unless they occur in known epileptics and seem to take the place of attacks, cannot be considered at all as equivalents.

*Diagnosis:* The diagnosis consists in the recognition of the types just outlined and in noting the result of long standing epilepsy, for example, the facies epilepticus, changes in disposition, and the insanities and criminal states that may follow. The description of the convulsions of the various types are so familiar that I shall not detail them here, except as a matter of interest to quote from Lucretius his word picture of a major fit, penned over 2,000 years ago.

Of, too, some wretch, before our startled sight,  
Struck as with lightning, by some keen disease  
Drops sudden: By the dread attack o'erpowered  
He foams, he groans, he trembles, and he faints;  
Now rigid, now convulsed, his laboring lungs  
Heave quick, and quivers each exhausted limb.  
Spread through the frame, so deep the dire disease  
Perturbs his spirit; as the briny main  
Foams through each wave beneath the tempest's ire,  
He groans since every member smarts with pain  
And from his inmost breast, with wantless toil  
Confused and harsh, articulation springs. . . .  
But when at last the morbid cause declined,  
And the fermenting humors from the heart  
Flow back, with staggering foot first treads,  
Led gradual on to intellect and strength. (1)

Having noted the especial type of an attack, we must watch for its recurrence to confirm our diagnosis. I believe, however, that many of the convulsions of infants and some so called fainting attacks of adults are cases of epilepsy with a single manifestation in which the convulsive habit is never formed. The chief consideration in the distinctive diagnosis of idiopathic epilepsy is to separate the disease from hysteria. The unfortunate term *hysteroepilepsy*, frequently taken to mean a combination of the two diseases, has been a dumping ground for both and has kept physicians from attempting to separate the forms of either. Gowers doubts the existence of *hysteroepilepsy*, while the last editions of Church and Peterson and Purves Stewart ignore it in their indices. It no more exists than does typhomalaria. The two conditions may exist independently in the same individual, but, through some wise provision of Nature, this is rare. The very type of an hysterical personality is frequently at the opposite pole from an epileptic disposition.

In hysterical convulsions the patients fall, if they fall at all, without injury, and they often talk and scream during the attack. The eyelids usually quiver, the pupils react to light, the movements of their extremities are wide and purposive, they may fight, or beat at surrounding objects or people, their

position takes the character of a pose, and there is usually no after stage of stupor, while various anesthetics and other hysterical stigmata may usually be found. The tonic then clonic stage of convulsion, biting of the tongue, foaming at the mouth, and other symptoms of epilepsy are absent.

I happened to have had the pleasure in London of hearing Sir William Gowers read his recent paper on Vagal Attacks which are due to disturbance of the vagus nerve. These have a sense of gas and fullness in the stomach, dyspnoea, inability to concentrate attention, and a sense of coldness or rigor. Consciousness is not lost. This condition has been mistaken for epilepsy.

*Pathology.*—Coming to pathology, only a few of the main points can be considered here, but they are the new ones and are of greatest importance. That there is a pathology to the so called idiopathic epilepsy has been denied, but the work of the last few years, and especially that of Dr. John Turner, of England, from whom I largely quote, has done much to clear the field and to put epilepsy in the class of organic nervous diseases and upon a very fair pathological basis. The changes in the brain tissue previously noted as taking place are those supposed to result from the effect of many convulsions, and consist of dilated bloodvessels, increase in the neuroglia elements, and atrophy of the convolutions. I believe with Dr. Turner that there is a congenital developmental defect in most cases, and this conclusion has been reached from his many examinations of epileptic brains. He says: "The occurrence of epilepsy in persons who are sane is not necessarily an objection to this view, as congenital, structural defect may coexist with average intelligence." He has found changes indicative of cerebral congenital defect, such as diminution of the number of nerve cells in cortical areas, changes in these cells and their nuclei, and changes in the nucleoli, especially of the Betz cells. The changes which occur as the immediate cause of an attack are intravascular clotting, either formed by masses lying free in the vessels (which are probably an amalgamation of blood plates), or hyaline material formation, or finely granulated debris, or fibrin threads. These changes were found in over eighty per cent. of a large number of epileptic brains examined. From these and similar investigations he reaches the conclusion that "there are two factors whose cooperation is necessary before a fit can result: a. A brain hereditarily and structurally predisposed to instability and convulsion; b. A sudden deprivation of the normal blood supply." The immediate cause being "cortical stasis resulting from obstruction of the blood supply by intravascular clots." (2)

Hulings Jackson advocated the latter point of this view in 1864, but could not prove it and did not include the congenital structural defect which Turner believes to be essential.

Chemical examination and microscopical analysis and estimation of the blood elements have proved of no conclusive value. In view, however, of the intravascular clotting found, the blood coagulation time was found to be greatly reduced in nineteen out of twenty-three cases examined by Turner just before, during, and shortly after the convulsive seizure. It is a well known clinical fact that the

wounds of epileptics heal quickly, showing a tendency to rapid blood coagulation. (3)

It is believed that some cases of autointoxication thicken the blood and may cause a convulsion in a person with a congenital structural cerebral defect. Dr. William J. Taylor, of Philadelphia, called my attention some time ago to the fact that thyreoid extract given internally would decrease the coagulation time of the blood. This was tested successfully at the Orthopædic Hospital and Infirmary for Nervous Diseases of Philadelphia in cases of hæmophilia. (4) Such being the case, thyreoid extract given to epileptics should increase the frequency of the convulsions. This, of course, is a line of investigation which we hesitate to explore.

The testimony of examiners of the urine, sweat, and cerebrospinal fluid of epileptics has been conflicting and uninformative.

*Prognosis.*—The prognosis of the disease under consideration depends much upon the type to which the case belongs. It has been considered an almost hopeless disease to cure or ameliorate. However, statistics show that from seven to ten per cent. of all cases are really cured, while in a larger percentage the attacks are arrested for a time and the condition improved. It must be remembered in estimating the seven to ten per cent. cured that the worst and most chronic forms of epilepsy in colonies and asylums are included, and that many cases seen in private practice of the milder forms have not been considered, hence the conclusions are entirely too pessimistic.

Various authorities estimate that an arrest of seizures from three to nine years should constitute a cure. The writer believes that after five years without an attack we are justified in calling the patient cured. An opinion based upon the recent literature of the subject and observations in clinics leads me to believe that the prognosis as to cure, in all cases outside of the insane class, provided the best treatment and regulation of life is strictly adhered to, is from twenty to twenty-five per cent., and that from sixty to seventy-five per cent. can be greatly improved with the same proviso.

Cases treated between ten and twenty-five years of age seem to have the brightest prospect of cure. The more frequent the attacks and more long standing the manifestations of the disease the worse the prognosis. The diurnal is said to have a better prognosis than the nocturnal, major better than the minor or combined type of attacks, while in psychic, serial, and status epilepticus the prognosis is worst of all. The curability seems to depend upon whether or not we are able to arrest the convulsive habit in these congenitally defective brains, and upon our ability to get the blood in such a condition that local or general cerebral stasis does not occur.

*Treatment.*—The treatment of epilepsy would be subject matter enough for quite a long paper and can only be outlined here.

In each case we must bear in mind the following: First—and this I wish to insist upon—the case must be classified as to which especial type of the disease it belongs. Second, the treatment must include the search for and the correction of all reflex causes. Third, each individual case must be managed with reference to habits, diet, occupation, education, rest,

etc. Fourth, the patient must continue under observation at regular intervals for years, and an exact list kept of the occurrence and character of convulsions. Fifth, patients having frequent, uncontrollable convulsions, or who are dangerous to themselves or to others, or who cannot receive supervision and care at home, or who develop insanity, should be sent to colonies or institutions for treatment.

Every conceivable drug has been used in epilepsy, and during the last fifty years the bromine salts more than all others. They have not proved specific by any means, and at times the end result of bromism, acne, lassitude, stupidity, etc., have been almost as distressing as the disease.

The sodium and potassium salts are upon the whole the best, and thirty to forty-five grains daily is the usual dose. Much larger doses may be given in conjunction with purgatives, massage, and hot baths. The action of the bromides is aided by a "salt free diet," and this procedure, even when the bromides are not used, gives marked beneficial results. The method was introduced by Toulouse and Richet. To keep the patient from becoming demineralized, sodium phosphate was given. (5)

Turner highly recommends a "purin free diet." The base of purin substance is C<sub>4</sub>N<sub>4</sub>. Dr. Walker Hall gives the following articles as purin free: Milk, eggs, cheese, butter, sugar, white bread, rice, tapioca, cabbage, cauliflower, lettuce, macaroni, strawberries, and olive oil, and another list, including potatoes, onions, oatmeal, beans, carrots, kale, spinach, dates, figs, asparagus, and codfish, as being purin poor; and salmon, halibut, beef, pork, mutton, chicken, veal, liver, and sweetbread as purin rich foods. (6.)

At Chalfont Colony in England the decreased purin diet is said to have proved very effective.

The patient should be very moderate in the use of coffee and tobacco. Pastries, candies, and alcohol should be practically excluded. All forms of excitement should be avoided. Baths, hot or cool, should be regularly given, and the bowels should be kept open. Convulsions may often be aborted by controlling the aura if present. This may be done if an aura begins locally in an accessible part, by sudden compression, or, in any case of psychic or sensory aura, by the administration of nitroglycerin one hundredth to one twenty-fifth of a grain (7), or by the inhalation of minims five of amylnitrite. In attacks known to come on at regular times sodium bromide, grains twenty, should be given two hours before the fit is due.

In petit mal or in nocturnal epilepsy chlorotone, grains three, morning and night, should be given. I have seen brilliant results from this remedy. Trional often has a good effect in the nocturnal form.

In grand mal, and combined grand mal and petit mal, the bromides, sodium borate, or fluid extract of *Solanum carolinense*, are our best drugs. Often it is advisable to change from one of these remedies to the other. If the convulsions are close together bromides may be increased quickly to as high as two hundred grains a day, and after they are controlled for a few days, reduced quickly to the ordinary dose. It is important in administering this drug in ascending doses to give massage, hot baths, and purgation at the same time to prevent bromism.

In serial epilepsy chloral in small doses in addition to other medication, and rest in bed, may cut short the series. Chloral is also indicated in status epilepticus if the patient is strong. In the stupor following status epilepticus give liquid food by mouth or bowel, and do not hesitate to stimulate with whiskey or strychnine if there are any signs of collapse. For psychical epilepsy hyosine or doboisine should be added in small doses to the bromides. As malaria in some cases seems to aggravate or to be the exciting cause of epilepsy, it should be borne in mind that quinine is of supreme value in these cases.

**Conclusion.**—In conclusion, allow me to submit that we should look upon epilepsy as an organic nervous disease with a pathology of its own, that we should admit the majority of all cases to be helpable, and a goodly percentage curable, and that, if we will turn from the apathy of the past and adopt the more modern methods of diagnosis and treatment, we may aid in the inauguration of a new and optimistic era for this much dreaded malady.

#### MULTIPLE CONCEPTION.

By M. J. KARPELES, M. D.,  
Germantown, Philadelphia.

The birth of triplets, according to statistics, occurs once in 7,910 births. This infrequency, therefore, warrants the report of this case. I have attended women who have given birth to twins, and this as a surprise, but when a retail engagement becomes a wholesale one, the surprise is all the greater.

Multiple conceptions may result in the birth of twins, triplets, and quadruplets. A number of instances of five children at one time are recorded, and even an apparently trustworthy case of the birth of six—four boys and two girls—has been reported by Vessali. The most extensive statistics examined with a view of determining the relative frequency of multiple conceptions is that studied by G. Veit, which included the records of 13,000,000 births in Prussia. According to this report, twins occur once in eighty-eight births, and, as stated before, triplets once in 7,910, and quadruplets once in 371,126. Recent statistics by the Boards of Health of New York and Philadelphia place the frequency of twin births in these cities at one in every 120 births. Twins are more frequent in multiparae than in primiparae. Individual and hereditary tendencies seem to be factors in the occurrence of multiple conceptions, as will be shown in the case I am reporting, and female twins often give birth to twins. Triplets may originate from a single ovum, from two or

three distinct eggs, a frequent arrangement being that one child is derived from a distinct ovum and two from a single ovum. Upon the manner of their origin depend the arrangement and relation of the placenta and membranes.

Plural conceptions may result from a single coitus whereby are impregnated ova which have simultaneously been discharged from the sexual gland, prepared for the reception of the male elements. On the other hand, repeated impregnations may occur after different though closely following sexual acts, these resulting in the fecundation of different ova which have been liberated at slightly different moments, but which belong to the same ovulation.

This possibility received recognition in the term "superfecundation," by which is understood the fecundation of two ova belonging to the same period by different sexual acts. Conspicuous examples of such occurrences are afforded by instances where a negress gave birth to a white and a black child. The only rational explanation is that in each case each child shows a different paternity.

A mare may be covered by a stallion and at an interval following from a few hours to fifteen days is covered by an ass; she has twins, one a horse, the other a mule.

A bitch in heat is covered by different dogs, and in her litter the puppies may indicate different fathers. I might add here, to avoid any suspicion of multiple racial paternity, that all three of these babies reported are white.

Tarnier's statistics show that in more than two thirds of multiple pregnancies the labor is premature; the reason for this fact is the great distention of the uterus.

The case is as follows:

E. O., age thirty-one, married six years. Had first child eleven months after marriage, female; second child fifteen months later, also female; one and a half years later, miscarriage of twins, male and female. Fifteen months later, another female child. Two years later, triplets. Aunt on mother's side had ten children, which included both twins and triplets.

The beginning of February I was called to see the patient at 6 a. m. This was three and one half weeks before the date of her expected confinement. On examination I found the bag of waters ruptured, position left occipitoanterior. Labor was well advanced, true labor pain every ten minutes, which rate continued about an hour. The pain after that came every three or four minutes, and by 7 o'clock she was delivered of this baby, which weighed five and one quarter pounds. The cord was so short that it was necessary to clamp with two hæmostats and sever before the child could be fully expelled.

Placing my hand over the uterus, it seemed as large as before the delivery, and on examination I found a breech presenting and this bag unruptured. I anesthetized the patient with chloroform, ruptured one sac, and brought down the feet and delivered with very little difficulty. The uterus still was large, and on examination, to my great surprise, I found another with the head presenting. The patient was allowed to recover from the influence of the anæsthetic, and in course of fifteen minutes later pains set in at intervals of three minutes, which continued for twenty minutes, and the third child was delivered.

The second child weighed five pounds and the third four pounds, making a total of fourteen and one quarter pounds. All three were females, this making six female heirs and a twin miscarriage during her married life of six years. I was careful not to make traction on the cords until the triplets were born. I had little trouble in delivering the placenta, which was of course very large, giving the appearance of three placenta coalesced into one with three cords and three distinct attachments to the placenta.

While I had attended this patient during previous con-

finements, I did not see her during this last pregnancy until after labor had begun.

The babies were weighed today, April 2d, and recorded, respectively, five pounds eleven ounces, six pounds five ounces, and six pounds seven ounces. They are artificially fed.

60 WEST CHELTEN AVENUE.

## Our Readers' Discussions.

### A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at frequent intervals. So far as they have been decided upon, the further questions are as follows:

LXXIV. How do you treat sunstroke? (Closed May 15, 1908.)

LXXV. How do you treat cholera infantum? (Answers due not later than June 15, 1908.)

LXXVI. How do you treat acute articular rheumatism? (Answers due not later than July 15, 1908.)

Whoever answers one of these questions in the manner most satisfactory to the editors and their advisors will receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but not required) that the answers be short; if practicable, no one answer to contain more than six hundred words.

All persons will be entitled to compete for the prize, whether subscribers or not. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish. All papers contributed become the property of the JOURNAL.

The prize of \$25 for the best essay submitted in answer to question LXXIII has been awarded to Passed Assistant Surgeon Charles S. Butler, United States Navy, whose article appeared on page 1040.

### PRIZE QUESTION NO. LXXIII.

#### HOW DO YOU TREAT SEASICKNESS?

(Concluded from page 1044.)

*Dr. William C. Griggs, of Philadelphia, states:*

Whenever the textbooks recommend a large number of drugs for the treatment of a disease, the student is pretty safe in believing that not one of them is absolutely satisfactory, and that the longer the list is the less satisfactory are the remedies. This is at least true in the case of seasickness, where they range all the way from calomel to chloroform. In fact, just as "more pure air and less drugs" is becoming the rule in treating tuberculosis, so I believe "larger and better ships and less 'dope'" will prove the best preventative of seasickness.

It cannot be too strongly urged that many patients are sent to sea who should be kept ashore. If a patient can afford an ocean trip it is an easy way for a physician to shift the responsibility of an undesirable case upon the surgeon of a transatlantic liner, especially if that physician has not personally suffered the horrors of seasickness. Many a patient would be a good deal better off at the shore or on the mountains than in a twelve by eight stateroom on a steamer. Since globe trotting, however, has become such a fad, there are few physicians probably who are not called upon to give advice at least once during the summer.

Amongst these may be a man who has just been planning a trip to Europe. The night before sailing

his friends give him a sendoff; probably they attend a theatre and afterwards adjourn to a restaurant for supper, and going upon the principle that "a man might as well hang for a sheep as a lamb," the prospective sailor eats heartily, maybe finishing up with a Welsh rabbit and champagne, and comes aboard the ship next day like a bomb with the fuse lit.

Here is another man: He has made up his mind that he will be seasick in the most orthodox fashion, and therefore prepares himself for the ordeal. For weeks he has been reading up on the subject, and in addition to a starvation diet, has purged himself and then taken all sorts and conditions of patent medicines, which, in spite of the fact that half of them have names which appear to have been taken out of a Chinese grammar and the other half stolen bodily from the outside of a Pullman car, rely for their effect upon practically nothing but chloral and bromides. That man would be seasick if he had a total gastrectomy performed upon him before sailing.

About midway between these two extremes, however, the vast majority of travelers will come, most of them nervous, especially if the trip be the first they have taken; and while in a great many cases it is impossible to entirely prevent the unpleasant experience they dread, it is without doubt possible to shorten it and make it more bearable.

First of all, the traveler should for a day or two before sailing prepare himself by not taking any rich foods or anything which he knows "disagrees with him." The day previous to sailing let him take 0.1 grain tablets of calomel every hour for ten doses or until the bowels have moved freely, and then, last thing before going aboard, eat a good, plain substantial meal.

Tell your friend to keep on deck as much as possible, have a good comfortable cane (not canvas, that gets wet and is difficult to dry) steamer chair, long enough to lie full length in, and a warm steamer rug or blanket; the latter is very important, for seasickness almost always makes a person feel chilly.

The first meal on the steamer is usually a hurried affair, everybody wanting to get on deck again as soon as possible, so as not to miss seeing the harbor, etc., and passengers are liable to "bolt" their food; under the circumstances a very bad thing to do. A little cold boiled ham or a sandwich or two is best; nothing hot or greasy should be taken; then on deck again. Do not omit this meal or the stomach becomes "empty" before the next one is ready, a condition which greatly predisposes to an attack of seasickness.

Personally I do not believe it is a good thing to "fight off" the nausea when it comes. Most people greatly dread to be the first to show the white feather, and hang on till the last possible moment. Better go to the rail and get it over and not prolong the misery; then, when the stomach has emptied itself, lie down with a soda cracker and munch it dry. These soda crackers are better than all the drugs ever used.

Retiring the first night and getting up the next morning are two dark, dark spots in most first voy-

ages, but "keep your head down when you once get it on the pillow" is a good rule, never mind how suggestive the unpleasant sounds from the next cabin may be. Call the steward to bring a little hot tea and more soda crackers twenty minutes before you try to get up next morning, then jump into your clothes as fast as you can and get on deck, and don't go into your stuffy cabin again before you have to.

Always go to the dining saloon at meal times, even though you have to beat a hasty retreat immediately after. It may not be a very Christianlike sentiment to feel good when looking at the rows of empty seats and the idle stewards, but the fact remains it will help you a lot. Take a few more soda crackers with you when you return on deck and munch them dry, and when the deck steward comes around with the beef tea at "eight bells" you will probably find you can not only retain a cupful, but will really enjoy it.

There are practically no drugs here, it may be noted, because in a simple case such as I have outlined I do not believe they are of any practical benefit. Of course, there are cases which demand them. Some persons become dangerously ill; one case I recall of a woman in the second month of pregnancy who almost died during a trip across the Atlantic in November, and another similar case in the Mediterranean Sea, the latter aborting on the fourth or fifth day. Here iced brandy, very small doses of malted milk at frequent intervals, with sufficient morphine, given hypodermatically, is the most satisfactory treatment.

*Dr. Charles Haase, of Elmira, N. Y., remarks:*

Nothing is of more value in treating those subject to seasickness than a preparatory treatment. Get the digestive tract in good condition by excluding from the diet for one week previous to sailing the following: Nuts, salads, pastry, condiments, fats, bonbons, fried foods, and farewell dinners. On the second night before sailing, one grain of calomel in divided doses is taken, to be followed in the morning by a Seidlitz powder. The Seidlitz powder to be repeated every morning for four or five days.

For weak individuals strychnine sulphate 1/60 grain, and fluidextract of ergot  $\text{M} \text{v}$  are given three times a day after meals. This dose to be doubled on the voyage. For robust individuals sodium bromides in 20 grain doses three times a day, after each meal, is of more value. It is to be given three days previous to and the first three days of sailing.

On board ship it is important that small quantities of easily digested food be taken at short intervals, at least every three hours. Liquids in small quantities should only be taken at meal times, as the rolling around of fluids in the stomach tends to produce nausea. Remain on deck as much as possible. Do not neglect taking exercise, and there is none better than walking. Avoid thinking and talking about seasickness. Have your stateroom thoroughly ventilated, as ship odors are a factor in the causation of seasickness.

In mild attacks of seasickness, with headache, the application of the constricting bandage to the neck and a reclining position in a deck chair, with the

eyes closed, is usually all that is necessary. The bandage relieves the anæmia of the brain and the closing of the eyes prevents optic vertigo.

In more severe cases, where nausea and vomiting are present, a glass of lukewarm water or some weak emetic is given to clean out the stomach. The patient is placed in bed, with the head low, eyes closed, and the constricting band applied to his neck. A large dose of magnesium citrate is given by the mouth, and if this is not retained an enema is given. Then a hypodermatic injection of atropine sulphate 1/100 grain, and strychnine sulphate 1/60 grain, is injected into the epigastrium.

A mustard plaster over the epigastrium and an ice bag to the nape of the neck often adds greatly to the patient's comfort.

In cases where the blood pressure is low, and it is so in most cases, strychnine sulphate 1/30 grain, and fluidextract of ergot  $\mathbb{W}x$  should be given every three to six hours, as indicated.

In exceptional cases it may be necessary to give a hypodermatic injection of morphine to control vomiting.

Clam broth, strong black coffee, beef juice, peptonized milk, grape fruit juice, lemon juice, dry toast, and salted crackers are some of the foods most easily retained. The individual's liking or longing for certain food is usually a good indicator of what the stomach will take care of.

*Dr. Samuel Stalberg, of Philadelphia, says:*

The passenger should put himself in the best physical condition before coming on board ship. He should avoid the fatigue and irregular meals usually attending the preparations for the departure. Only easily digestible food should be taken for a few days preceding the voyage. One quarter grain calomel for eight doses, followed by a bottle of solution of magnesium citrate, should be taken on the day of sailing. In the bilious this may be replaced by a few pills containing calomel and podophyllin. The berth selected should be as near amidships as possible, well ventilated, and free from odors. The larger, steadier, and slower going boats should be selected. Straining of the eyes and looking at the water should be avoided. For the first few days the meals should be light, taken often.

When the first symptoms of the attack present themselves, such as lightheadedness, dizziness, headache, and epigastric uneasiness, the passenger should assume a horizontal position in bed, or in a sailor's hammock on deck, well protected against direct sunlight and a view of the ocean. A bowl of hot soup or cup of coffee should be taken, and in cases that do not go beyond this stage, this will be sufficient to restore the disturbed equilibrium and relieve cerebral hyperæmia, sending the patient on his way to recovery.

In the majority of cases, however, these symptoms are but the beginning, and nausea, vomiting, vertigo, faintness, and mental depression follow. These patients should maintain the horizontal position, and keep their bowels open by the effervescent magnesium citrate, Seidlitz powder, or some mineral water. The diet should consist of clam juice, nutritious soup, and pasteurized milk, which can be

pancreatized or diluted with equal parts of vichy or lime water, or it may be taken with ten grains of sodium bicarbonate and three grains of cerium oxalate to the tumblerful, and kumyss and matzoon. In some patients solid food is better than liquids for the vomiting, and they should try soda crackers, zwieback, lemon ginger snaps, and chipped smoked beef. All of these, as well as bottled milk and clam broth, should be taken along when going on board. Fresh lemons, oranges, and lime water tablets are often gratifying. Daily baths of cold water, or hot water followed by friction or by a cold douche, should be taken. The patient should be made as cheerful as possible.

In patients in whom nausea and vomiting are persistent, and exhaustion is marked, strychnine sulphate, grain 1/48, and atropine sulphate, grain 1/240, should be given hypodermatically, three or four times daily, until recovery sets in. The atropine and strychnine solutions should be kept separately, but given together, so as to better regulate their administration in accordance with their effect. They may be given by mouth, if retained, in the form of tablets, but these tablets should never be entrusted to the patients themselves. Where there is marked headache, potassium bromide, grain xxx, three times a day, should be given.

Cerium oxalate, grain iii; bismuth subnitrate, grain x, and codeine sulphate, grain ¼, may be tried if the vomiting is persistent. If nausea is constant and vomiting does not follow, it is well to unload the stomach by a light emetic, such as a glass of lukewarm water to which is added salt, or a few teaspoonfuls of the wine of ipecac. Hot water bags and mustard leaves or plasters to the epigastrium should be applied. When patients crave sour articles to relieve the bad taste in the mouth, such as sour pickles, lime juice tablets, etc., these may be cautiously allowed. Small pieces of cracked ice may be swallowed.

Few persons will go beyond this stage, but those that do are alarmingly ill, and the prostration is marked. In these cases, hot water bottles should be kept along the limbs, and the latter rubbed briskly with alcohol. The stimulating and supporting treatment mentioned before should be carried out. A hot compress to the forehead, and a broad rubber band tied around the neck with a moderate amount of pressure, on the principle of Bier's hyperæmia method, should be tried. An ice bag to the spine may be tried. It is in these cases that the various mechanical devices calculated to lessen the effects of the movements of the boats, though usually useless, may be tried. These are the swinging staterooms, berths, and bunks, the Bessemer suspended saloons, and the electrically vibrating chair.

Schlick, a Hamburg naval engineer, has recently invented an apparatus which may prove of real value in limiting the rolling motions of the boat. This apparatus is designed at the same time to increase considerably the period of oscillation of the rolling movements and to diminish the amplitude of the oscillation. This is based on the gyroscopic effect of a flywheel mounted on board a steamer and caused to rotate rapidly. The vertical axis of the apparatus is so located as to be able to move pendulum-

like in the central plane of the ship. The rapid oscillations of the wheel will result in rendering the patient insensible to the effects of the wave motion, the rolling movements being practically eliminated. The underlying principle of the apparatus is the fact that a rotating body will oppose to any inclination of its axis a resistance higher, as its rotation is more rapid and its weight more considerable.

Those affected with acute disease, and those with diseases like aneurysm and hernia, in which the mechanical effect of the vomiting might be disastrous, should abstain from undertaking a sea voyage. While a treatment, as stated, is in the main symptomatic and aiming at rationality, still it was attempted to recognize that seasickness is primarily a neurosis, the movements of the vessel causing disturbances of equilibrium in the brain centers, the visual and aural disturbance probably also contributing their stimuli. This disturbance causes vertigo, malaise, etc., and the sympathetic being involved, nausea, vomiting, and prostration following. Due to vasomotor disturbance, anaemia of the centres follows, and heart weakness results. Therefore stimulating rather than depressant treatment is recommended.

### Correspondence.

#### LETTER FROM LONDON.

*Mr. Moynihan on Gastroenterostomy.—The Proposed Removal of King's College Hospital.—The Registration of Nurses Bill.—An Antivivisectionist Meeting.—The Royal Academy Pictures.—The Franco-British Exhibition.*

LONDON, May 18, 1908.

At a recent meeting of the Sunderland Branch of the British Medical Association, Mr. Moynihan, the well known Leeds surgeon, gave an address on the operation of gastroenterostomy. As a leading exponent of gastric surgery in England, Mr. Moynihan was an ardent advocate of this operation. With the improvements in method and technique the operation mortality has gradually fallen and in the hands of some surgeons is now less than two per cent. It was therefore, he said, scarcely surprising that this operation should be performed with increasing frequency, the indications for its performance growing more numerous from time to time. Mr. Moynihan's teaching has been generally accepted, and many surgeons hold the view that if laparotomy is performed for supposed organic disease of the stomach and none is found it is advisable to proceed to the performance of gastroenterostomy, apparently on a similar principle to that of those surgeons who remove the appendix whenever they operate in that region, whether it is diseased or not. Out of 205 patients upon whom this operation had been performed by Mr. Moynihan, there were eleven in whom no organic disease was found. Now that he has had a further opportunity of studying the after results of his cases, Mr. Moynihan expresses himself as being distinctly antagonistic to the performance of this operation except when demonstrable organic disease is present. In func-

tional stomach conditions the after results are almost invariably bad, the patients either remaining in the same condition or their symptoms being aggravated by regurgitant bilious vomiting. No improvement is to be expected in those cases in which the pylorus remains patent. Experimental work has shown that if gastroenterostomy is performed on healthy animals, all the stomach contents continue to pass out by the natural opening, the artificial one not being used at all. Thus in cases of an ulcer on the lesser curvature, near the cardiac end, the pylorus remaining normal, gastroenterostomy not only is useless, but may be harmful, and the best treatment in such cases is excision of the ulcer. Mr. Moynihan's conclusions are of considerable interest and will, no doubt, have some influence in producing a reaction in favor of conservatism in this operation.

Considerable interest is being aroused in the proposed removal of King's College Hospital, one of the large metropolitan teaching hospitals, to Denmark Hill, in South London. The general practitioners of the South London district, who will be most affected by the change, have held a large meeting to discuss various matters in connection with the hospital. Several resolutions were proposed and accepted relating to the methods of managing the hospital, and it was intended to place these resolutions before the hospital committee. They related chiefly to the question of hospital abuse, one of the most important being that out patients should not be seen at the hospital, except on production of a certificate from a medical practitioner stating that the patient was a suitable person for hospital treatment. These certificates would be given by the general practitioners free of charge. Another resolution proposed was to the effect that the out patient department should only be consultative. A medical man wanting a specialist's opinion on a case where the patient could not afford to pay a consultant's fee should be able to send this patient to the hospital with a letter, and after seeing the patient the consultant should outline the treatment to be adopted in a letter to the medical practitioner, who would continue in attendance. At the Bolingbroke Hospital, Wandsworth, one of the smaller hospitals, this system has now been in vogue for some time and is very successful. The question of the admission of paying patients to the hospital was next considered, and a resolution was carried unanimously to the effect that in a hospital supported by charitable contributions this was a mistake. Doubtless the general practitioners in the district will be adversely affected to some extent by the advent of a large hospital. The decentralization of a large teaching hospital is certainly an innovation. We have got used to the idea of having all our large hospitals in the heart of the city. But the increasing growth of the suburbs affords plenty of scope now for the existence of large hospitals outside the central area, and the example of King's College may possibly be imitated by another large hospital.

Medical opinion in England is divided on the question of the state registration of nurses. The British Medical Association had the subject under consideration for two years, and it was fully dis-

bated in all its aspects. Finally, at the annual general meeting in 1906 the principle was approved of. The General Medical Council, the body controlling medical registration, was also in favor of the principle. Yet on Wednesday last, May 6th, the second reading by Lord Balfour of Burleigh's Official Directory of Nurses' Bill, which requires "that an official directory be kept on which shall be entered the names of all nurses who have received an adequate training," was rejected in the House of Lords by 53 votes to 20. The debate on the bill showed that, although most of the speakers were in favor of some form of state control over the nursing profession, the present bill did not supply an adequate method of dealing with the question. It did not provide proper representation of the nursing and medical professions, neither would it guarantee the efficiency of those registered.

The Antivivisectors have not been long in retaliating upon the Research Defense Society. On Tuesday, May 12th, they held a large meeting at the Caxton Hall, Westminster, with the object of "making a demonstration against vivisection and the principles, tactics, and misleading title of the newly formed Research Defense Society." It was stated that this society lacked courage to send a speaker to debate with them. They had written to Mr. Stephen Paget, the honorary secretary, asking him to send a speaker to meet one of the Antivivisectors in a public debate, the question to be discussed being Is Vivisection Morally Justifiable and Scientifically Necessary? but their challenge was not accepted. This is scarcely surprising in view of the insults and extravagant statements of some of the Antivivisectors, but the presence of Mr. Paget at the meeting and his very effective speech showed that he did not lack the courage to beard the lion in his den. It would not serve any useful purpose to make further comments on the proceedings at the meeting, but a comparison of the names of those constituting the Research Defense Society with the names of the leading Antivivisectors will at once show thinking men which side to follow.

Some of the pictures at the Royal Academy this year have a decided medical interest. There is one by the Hon. John Collier, entitled The Death Sentence. It portrays an intellectual looking physician giving advice to a young man who is obviously suffering from some severe illness. His malady may be open to speculation by physicians, but the aspect of the patient is most like one affected with tuberculous disease. The picture displays realism and the situation is dramatic, but it is not a very unusual occurrence in the busy physician's life. There is also a good portrait of Dr. Pridgin Teale, and among the sculptures is a bust of Hughlings Jackson.

The opening of the Franco-British Exhibition at Shepherd's Bush took place on Thursday, May 14th. The wretchedness of the weather and the general state of unpreparedness combined to mar the opening function somewhat. None of the medical or scientific exhibits, of which there will be quite a large number, were ready for inspection, and it will be some time before the various exhibits reach the stage of completion.

## Therapeutical Notes.

**Treatment of Pain from Biliary Calculus.**—A paper by Robin on the treatment of biliary calculus, published in the *Bulletin médical*, is summarized in the *Journal de médecine et de chirurgie pratiques*. For the relief of pain he does not use morphine hypodermatically, except in particularly painful cases and such as do not respond to a sedative like the following:

B	Potassium bromide, .....	3iiss;
	Morphine hydrochloride,	
	Aqueous extract of belladonna, .....	ãã gr. ¼;
	Syrup of ether, .....	5i;
	Cherry laurel water, .....	3iiiss;
	Valerian water, .....	3iiiss.

M. et sig.: One tablespoonful every half hour until three or four doses have been taken.

While this medicine is being taken apply over the region of the liver a piece of flannel soaked in the following liniment:

B	Compound oil of hyoscyamus, N. F., .....	3x;
	Extract of opium,	
	Extract of belladonna,	
	Extract of hyoscyamus, .....	ãã 3ss;
	Chloroform, .....	3iiiss.

M. ft. liniment.

The third thing to be done is to evacuate the intestine. During an attack of biliary colic, the intestine, like the biliary duct, is in a state of spasm, and the mildest form of enema must be used. This consists of water which has been boiled and allowed to cool to the temperature of the room; such an enema exerts a cholagogue and evacuant action on the liver.

In cases where the foregoing means of overcoming the pain prove insufficient, recourse must be had to hypodermatic injections of morphine, hot sedative baths, or to a sedative mixture of chloral, chloroform, and glycerin, according to the following formula of Manquat:

B	Syrup of chloral,	
	Glycerin, .....	ãã 5i;
	Chloroform water,	
	Cinnamon water, .....	ãã 3iss.

M. et sig.: One tablespoonful every fifteen minutes until the pain is relieved.

The vomiting which is reflex in its nature is readily controlled by the administration of six drops of the following mixture, given in a little warm water:

B	Picrotoxine .....	gr. 3/4;
	Alcohol, enough to dissolve the picrotoxine,	
	Morphine hydrochloride, .....	gr. 3/4;
	Atropine sulphate, .....	gr. 3/20;
	Vyon's ergotine, .....	gr. xv;
	Cherry laurel water, .....	3iii.

M.

Five or more doses of this are given during the twenty-four hours, but the vomiting will usually cease after the second dose.

As medicine to be taken regularly during the day the following powders are prescribed with which to make phosphobenzoated water:

B	Sodium bicarbonate, .....	3iii;
	Dried sodium sulphate,	
	Dried sodium phosphate, .....	ãã gr. xlv;
	Sodium benzoate, .....	gr. xv.

M. ft. chart. No. 1.

Sig.: One powder to be dissolved in a quart of boiling water. Take a wineglassful on rising; and one and one half glassfuls (three ounces) at 10 o'clock a. m., and at 5 and 10 o'clock p. m.

Under Domestic Postage Rates, \$5; under Foreign Postage Rate,  
\$7; single copies, fifteen cents.

Remittances should be made by New York Exchange or post  
office or express money order payable to the A. R. Elliott Pub-  
lishing Co., or by registered mail, as the publishers are not  
responsible for money sent by unregistered mail.

Entered at the Post Office at New York and admitted for  
transportation through the mail as second class matter.

NEW YORK, SATURDAY, JUNE 6, 1908.

## THE MEDICAL RESERVE CORPS OF THE ARMY.

The Act to Increase the Efficiency of the Medical Department, United States Army, approved April 23d, contains a feature which must be of great interest to the medical profession of the country. The institution of a reserve corps of officers available for military service in war or other great emergency is distinctly a new departure in the military history of the United States, and if the attempt is a success there is reason to believe the principle of maintaining reserve forces may be extended along other and nonmedical lines, much to the advantage of the nation.

The immediate aid to the military medical service afforded by this provision of the recent act is that the contract surgeons now in service will receive commissions and enjoy the positions and emoluments of regular officers, instead of the unsatisfactory half military, half civil status heretofore occupied by them. The recent increase in army pay makes the new position also better worth having. The necessity for a considerable number of medical officers additional to those of the Medical Corps will continue for some years at least, as the increase in the regular force cannot under the act be fully obtained for four years, and unless much greater success than heretofore is had in securing properly qualified men, the corps is not likely to be entirely filled even in that time.

Candidates for the permanent corps will, after passing the preliminary examinations, be also commissioned in the Reserve Corps and placed on active duty until they have gone through a course of in-

struction at the Army Medical School, thus insuring them against loss of pay or future loss of rank in the Medical Corps when they are finally admitted.

The present advantages of this section of the act are, therefore, so manifest that the Medical Department may well be congratulated upon its passage, but it is hoped the Medical Reserve Corps of the future will be much more than a small band of assistants temporarily helping out the medical service of our little regular army. The President is authorized to commission as first lieutenants of the Reserve Corps properly qualified graduates in medicine who are citizens of the United States. The holders of these commissions, although not on active duty, will form a body of men available for service in emergency all over the land. They will be considered as having pledged themselves to serve the country professionally in time of war when called upon, although by no means necessarily as first lieutenants of the Reserve. Service to the nation in any capacity will be considered as carrying out the agreement.

The number of the Reserve Corps is not limited by law, and it is probable that the age limits will be so fixed that some of the older men of acknowledged eminence may be induced to enter and put a proper "cachet" upon the new corps from the beginning. We take for granted that physical soundness, good standing in the community, and legal qualification to practise will be required of all applicants.

The success of the scheme will depend entirely upon the interest taken in it by the best physicians and surgeons throughout the land. If, from motives of patriotism and national pride, representative men, and no others are wanted, enter the Reserve Corps, the War Department will be enabled to maintain contact with the medical profession of the country that will insure our soldiers, regular and volunteer, in future wars an adequate and efficient medical service. Except for the few who are employed on active service in time of peace, and the candidates for life careers in the army undergoing instruction at the school, positions in the Reserve Corps carry no emoluments of any sort. We believe, however, that the possession of the President's commission and the knowledge that one's name is registered among those willing to serve the country in her time of need will be sufficient attraction for the class of men particularly desired.

## THE EDUCATION OF THE PUBLIC IN MEDICINE.

Dr. Herbert L. Burrell, of Boston, the new president of the American Medical Association, chose a timely theme for his inaugural address before the annual meeting of the association, held in Chicago this week. We are indebted to the general secretary

for advance proofs of that and the other formal addresses. The title of Dr. Burrell's discourse was *A New Duty of the Medical Profession: the Education of the Public in Scientific Medicine*. Having paid a graceful tribute to the memory of the late Dr. Nicholas Senn and traced the progress of medicine from the condition of a satellite of theology to that of biological science applied to the prevention and relief of disease, the president proceeded to his subject proper.

Dr. Burrell is in thorough accord with the present feeling of the profession that the general public needs medical instruction from the best sources, not the self seekers and the covert advertisers, whom, he is quite sure, the people would not be slow to detect. He specifies four agencies by which the public may be educated in medicine. The first of them is newspaper articles authorized by a responsible board of medical men. "These articles," he says, "should be signed and published under the authority of the Board of Public Instruction. That these articles should be judiciously edited must be apparent to all. No statement issued by the Board of Public Instruction should fail to be the absolute truth. Irreparable damage to the medical profession and to the public might be done by unwisely exploiting mooted subjects." We presume it may be taken for granted that authoritative boards would be less likely to fall into the errors alluded to than enthusiastic individuals would.

The next agency mentioned is magazine articles written by skilled lay writers inspired by medical men of sound knowledge and discretion. This strikes us as an exceedingly hopeful means, only we may first have to disabuse the public of the extravagant appreciation which it has been taught to entertain of "the commercial value of a name," for that overappreciation is a real obstacle. The man who has done things and who knows things is not usually the one who can best expound them. Julius Caesar was a shining exception, but our Caesars are few and far between. We presume that the source of the lay writer's inspiration ought always to be indicated, but the intervention of the skilled writer is highly necessary.

The next agency mentioned is that of free public lectures. In regard to their efficiency, Dr. Burrell says:

These lectures should be given by men who are authorities in their subjects; and the experiment as it has been tried in various parts of the country, particularly in Chicago and at Harvard, has been a success. At Harvard during this last winter the lectures have been so popular that at times a hundred or more people have been turned away, being unable to gain admission. A wide range of subjects has been covered in these lectures. Many factors influenced the attendance: First, the subject selected; second, the individual who gave the lecture; and

third, the condition of the weather. Sunday afternoon lectures were better attended than Saturday evening lectures. Inclement weather markedly diminished the attendance. The most conspicuous factor that influenced the attendance at the lectures was the cooperation of the press. For example, when a lecture was given on a subject of great public interest, then if the press devoted from a half column to three columns to noticing it, the stimulus to the attendance at succeeding lectures was marked.

But Dr. Burrell is convinced that the most potent agency of all is individual teaching by the physician in the family, and we believe that the profession will cordially agree with him in this. He thinks that in public instruction it will be well to avoid attempts to cover too wide a field; we should rather seek to make the instruction thorough in a limited range, such as that of the infectious diseases, and notably, as is now being done, with regard to tuberculous disease. The address as a whole was replete with wisdom.

#### OUR RELATIONS WITH THE PUBLIC.

The association is to be congratulated on having selected so scholarly and broad minded a man as Dr. William Sydney Thayer, of Baltimore, to deliver the address in medicine this year. Dr. Thayer touches luminously on a number of points covered by the title of his address, *On Some Relations of the Physician to the Public; Duties and Opportunities*. We can mention only the more notable of them. The subject of malaria receives considerable attention. The Hellenic Peninsula, Dr. Thayer reminds us, is still cursed with the prevalence of malarial disease, and he implies that the decadence of the Greeks of ancient times may be traced to the sapping of general health among them by that infection. In Italy, on the other hand, malaria is well on the road to suppression as a result of vigorous sanitation. In our own country we may take a lesson from what has been accomplished in some of our dependencies, particularly in the Panama Canal Zone, in the prevention of disease. Of the work on the canal, "one of the greatest undertakings that man has ever essayed," Dr. Thayer says:

The French, with unexcelled mechanical skill and energy, had failed—failed largely because of the dreadful and continued mortality among the workmen. The United States took up the work. In the mean time there had come the great discoveries of Ross and Grassi and Bignami and Bastianelli, completing those of Laveran, concerning malaria, and the vital and illuminating contributions of our own Reed, Lazear, Carroll, and Agramonte, with regard to yellow fever. And to-day the Panama Zone compares favorably, as to sanitary conditions, with the more healthy parts of this country. Yellow fever, though on all sides, is here unknown. It is the greatest triumph of preventive medicine that the world has ever known.

Dr. Thayer depicts vividly the difficulties too frequently met with by physicians in inducing persons

in authority to listen to arguments in favor of hygienic precautions, instancing "an eastern city" whose authorities suffered an engineer to stifle the pleadings of medical men who insisted on proper measures for insuring the salubrity of the water supply. It would have done no harm, we think, if he had mentioned the city by name; municipalities are in great need of having such blunders brought home to them specifically.

Frankness with patients, as a part of the public, is another of the great duties which Dr. Thayer insisted upon—frankness associated with optimism. The mysterious, the impressive, the oracular, he said, should be discarded in our intercourse with the sick. "Truth," he reminded us, "is as sacred a duty in medicine as anywhere else in life," and he forcibly cited Cabot as having said: "The doctor's lie is always detected."

### THE CANCER PROBLEM.

This was the title of the address in surgery by Dr. George W. Crile, of Cleveland, delivered before the meeting of the American Medical Association in Chicago. Not only, in our opinion, was it the gem of all the formal discourses, but also such a pronouncement as cannot fail to remain a landmark, and a bright one, in the history of the present worldwide endeavor to solve the problems of malignant disease. It is no wonder that those who heard it were profoundly impressed. There is no circumlocution about Dr. Crile's way of putting things, no shadow of uncertainty as to his meaning or as to the depth of conviction from which he speaks; his incisiveness, indeed, reminds us of the late Dr. Henry B. Sands, and there is often observable in his style a verbal felicity that but few medical writers have ever possessed. The following expressions, for example, are worthy to be ranked with the late Dr. Roberts Bartholow's "therapeutic nihilism": "Cellular cannibalism" (referring to the destructive action of cancer) and "There is no tie of sentiment between a man and his cancer" (apropos of the feasibility of inducing a patient to consent readily to excision of a precancerous lesion).

Dr. Crile is optimistic in the matter of cancer, but his optimism is abundantly justified. Though he gives solid reasons for hopefulness as to the ultimate triumph of other means, he regards the knife as still practically the sole resource in rescuing the subjects of cancer. He presents an encouraging contrast between the "ghastly" statistics of operative results collected by Butlin twenty-one years ago and the brilliant consequences witnessed at the present day. But, he insists, the operation must be an early one, done in the precancerous stage if possible, and he justly scores those doubters in the pro-

fession who dally with a growth of yet uncertain nature until the period of hopefulness has been passed. "I have often thought," he says, "that, pending a more general enlightenment, it would be a great boon to mankind if the words 'glandular enlargement and cachexia' as denoting symptoms of cancer were stricken from every textbook of medicine. These are terminal symptoms, and indicate that the surgical opportunity is forever lost."

Early and thorough excision, under proper technique, having been demonstrated to be practically curative of readily accessible growths, Dr. Crile turns his attention to internal cancers. In common with many others, he is convinced that these tumors also have a precancerous stage, gastric cancer, for example, following upon a simple ulcer. Hence these possibly precancerous lesions should be removed. In the early diagnosis of internal cancer much dependence may be placed upon blood examinations turning upon the presence or absence of hæmolytic action. In cases that appear inoperable on account of the patient's bad condition, substantial assistance is to be derived from a properly conducted transfusion of whole blood or an infusion of serum, and there is good ground for expecting the establishment before long of immunization by serum treatment. We know of nothing in all our literature which is so encouraging in the struggle against cancer as this address of Dr. Crile's.

### THE AMERICAN MEDICOPSYCHOLOGICAL ASSOCIATION.

The sixty-fourth annual meeting of this organization, the oldest national medical association in the country, took place recently in Cincinnati, with an average attendance of over two hundred members. The meeting was marked by many pleasant social features, as members from all parts of the United States and Canada were in attendance; the hospitality of the State, the city, and the medical profession was most cordial, and the scientific programme was rich in records of earnest and progressive work in the special field of psychiatry.

In his opening address, Dr. Charles P. Bancroft, of Concord, New Hampshire, speaking of the hopeful and discouraging aspects of the psychiatric outlook, reviewed the progress of the past few years, showing how rapidly the science of psychiatry had been advancing, far more rapidly, in fact, than most of the members of the profession were aware, and thus progress, he said, had been no less marked in the sphere of the therapeutics of mental disease than in that of its more exact diagnosis. He emphasized the necessity for a broader outlook on the part of alienists if they were to discharge a fuller measure

of their responsibility to the social body, and spoke of the discouraging features implicated in the political management of many of our hospitals for the insane.

In Dr. Henry J. Berkley's paper, read by Dr. Hurd, on Thyroidectomy and the Thyreolecithin Treatment of Catatonia, the definite report of therapeutic advance was made with reference to this group of mental disorders. In well marked catatonic præcox cases, characterized by much motor disturbance, in the form of command automatism, negativism, stereotypy, catalepsy, etc., by the removal of part of the thyroid gland, done under certain surgical precautions, a definite and distinct amelioration had taken place in a fairly large number of patients. In some instances the change had been so marked and had occurred in so short a time that the effects seemed almost magical. The author, however, gave a very guarded estimate of the permanent value of the procedure, and expressed the opinion that the number of reported cases was still too small to permit of generalizations. In view of the active discussion that brought out the facts of the relatively good prognosis in this particular form of disturbance, the difficulties in diagnosis, especially of certain hysterical admixtures, the absence of definite biological concepts interpretative of the results, the general feeling shown was that of a hopeful productive conservatism that counseled further trials under rigid analysis of results.

The vexed problem of the presenile mental affections was attacked with hopeful results by Dr. E. E. Southard and Dr. H. W. Mitchell, of Hathorne, Mass. The coordination of clinical and pathological material in an analysis of some 400 cases was too exhaustive to permit of more than a brief note in this place. The author showed, however, that in some twenty insanities occurring in the sixth and seventh decades, which were studied post mortem, there was no need of regarding them as different in type, from the clinical or pathological point of view, from the insanities known to occur in other decades. Thus, one patient of over sixty, in the absence of any arteriosclerosis, showed the typical clinical picture of a dementia præcox; others were classical "manic depressives," the attacks occurring apparently for the first time in these decades. The paper was extremely suggestive in many directions and offered considerable light in a field much in need of investigation. A spirited discussion was held on the general subject of the bacteriology of general paresis, which we have presented in a separate editorial note. The paper of Dr. Henry M. Hurd, of Baltimore, was a masterly one—Psychiatry as a Part of Preventive Medicine. We shall comment upon it at a future time.

Speaking of the proper size of hospitals for the insane, Dr. Charles W. Pilgrim, of Poughkeepsie, made a searching analysis of this entire question. He traced the gradual growth of our hospital system from the days when 300 inmates were regarded as sufficient in number for one superintendent to care for properly, to the enormous piles in which 5,000 are domiciled. He showed that we now had had experience enough to determine the proper size for a hospital for mental disease, from the standpoint of economical administration and maximum efficiency in the treatment of the individual.

We have been able only to pick out here and there some of the interesting papers given before this association—there were many others equally important that space does not admit of our discussing.

#### INSTRUCTION IN HYGIENE AT WEST POINT.

The recent appropriation bill for the Military Academy at West Point provides that the Secretary of War may appoint a medical officer of the army as "instructor" of hygiene for the Corps of Cadets. The use of the word "instructor" instead of "professor," as heretofore, is most unfortunate and constitutes a step backward in the teaching of hygiene to the line of the army. A West Point "professor" is a personage with distinct rights and privileges. He has the rank of lieutenant colonel or colonel, and his assistants detailed from the army are "instructors." Professors are also members of the Academic Board. The professor of hygiene at the academy has enjoyed like privileges and, although a major in the Medical Corps, has been carried on the register with the temporary rank of lieutenant colonel. The position carried with it extra pay to the extent of five hundred dollars a year (the difference between the pay of a professor at the Military Academy and a major in the army). It appears that Congress objects only to the extra pay, and so substituted the word "instructor." The loss of pay to the officer in question, although it seems unfair to him, is not a matter of national importance, but the change of title is really a serious matter, as it minimizes the chair of hygiene and may possibly operate as a technical obstacle to the teacher of that branch serving on the Academic Board. The actual daily practice of military hygiene is necessarily in the hands of the officers who command men, and its foundation is discipline. The instruction, therefore, of future officers of the army in all that constitutes "care of troops" is of supreme importance, and the relegation of hygiene to an inferior place in the curriculum at West Point is much to be regretted.

# The American Medical Association,

Fifty-ninth Annual Meeting, Chicago, June 2, 3, 4, 5, 1908.

## The Meeting Reviewed.

With a registered attendance of six thousand four hundred members the fifty-ninth annual meeting of the American Medical Association establishes a new record for gatherings of medical men, for it can be safely asserted that never before were there so many physicians gathered together on one occasion. The central situation of the place of meeting, its accessibility, and the excellence of the programme all combined to make possible so large an attendance.

Although the scientific meeting was not called until Tuesday, the House of Delegates began its sessions on Monday, the 1st, at 10 a. m. A full report of the business of the House of Delegates will be found after this article.

**The General Meetings.**—The first general meeting was called to order at 10:30 a. m. on the 2d by the president, Dr. Joseph D. Bryant, of New York. After an invocation by the Right Reverend Charles Edward Cheney, D.D., bishop of the Reformed Episcopal Church, addresses of welcome were made by the Honorable Charles S. Deneen, governor of Illinois; the Honorable Fred A. Busse, mayor of Chicago; and Dr. H. B. Favill, the president of the Chicago Medical Society.

After the report of the local committee of arrangements was presented by Dr. M. L. Harris, of Chicago, Dr. Herbert L. Burrell, of Boston, was introduced and conducted to the chair. Dr. Burrell then delivered the address of the president (see page 1095).

The second general meeting was called to order at 7:30 p. m. on the 2d, by the president, Dr. Herbert L. Burrell, of Boston. The oration on medicine was delivered by Dr. William S. Thayer, of Baltimore. The oration on surgery was delivered by Dr. George W. Crile, of Cleveland, in the section on Surgery and Anatomy. Both of these orations have been treated in our editorial columns in this issue. At the third general meeting, which was held on Wednesday, June 3d, at 2 p. m., Dr. Charles Harrington, of Boston, delivered the oration on State medicine.

**The Scientific Business.**—The scientific business of the meeting as conducted in the various sections was up to the average of excellence so far maintained by this association. Lack of space prevents us from giving the gist of each paper read, but the reader will find abstracts of several important communications in proper sequence in the description of the meetings.

**Guests.**—Among the distinguished foreigners who were present as guests of the association may be mentioned Professor J. Hannenstiel, of Kiel, Germany, who spoke upon Abdominal Cervical Cesarean Section at the symposium on Cesarean section at the Tuesday afternoon meeting of the Section in Obstetrics and Diseases of Women; Professor A. Martin, of Greifswald, Germany, who spoke on Genital Tuberculosis at the Wednesday afternoon meeting of the Section in Obstetrics and Diseases of Women; Professor L. Brauer, of Marburg, Germany, who took part in the symposium on the surgery of the vascular system and read a paper on Positive Pressure in the Surgery of the Chest; Professor Jensen, of Berlin; Dr. Arthur Bahr, of London, who read a paper on the Surgery of the Abdomen; Professor Edward A. Schaefer, of Edinburgh, Scotland, who read a paper on Artificial Respiration in Its Physiological Aspects, and another paper on the Pituitary Body at the meetings of the section in Pathology and Physiology; Dr. F. Sauerbruch, of Marburg, Germany, who read a paper on the Present Status of Surgery of the Thoracic Cavity and the Significance of the Author's Method of Preventing Pneumothorax, in the section in Surgery and Anatomy; Dr. E. Treacher Collins, of London, who read a paper on the Developmental Deformities of the Crystalline Lens, and took part in the discussion on the treatment of simple glaucoma in the section in Ophthalmology; Dr. Charles E. Beevor, of London, who addressed the section in Nervous and Mental Diseases on Associated Movements.

**The Entertainments.**—The social features of the meetings of the American Medical Association are among its most important proceedings. The president's reception and the ball, which were held on Wednesday evening, were, of course, the leading social functions, and it was a great pleasure to watch the gay scene in which such a large number of physicians and their guests took such evident enjoyment. The Art Institute, on Michigan avenue, was open daily to those who wore the official badge of the association. Automobiles left from the Art Institute hourly from 10 o'clock every day, in which those who desired to see the city were taken to the various points of interest. There was an informal gathering of the ladies in the rooms of the Fortnightly Club, the Chicago Woman's Club, and the Chicago College Club on Tuesday afternoon, a reception at home of Mrs. Herbert L. Burrell at the South Shore Country Club on Wednesday

afternoon; a reception and a musicale by members of the Theodore Thomas Orchestra in the Art Institute on Thursday afternoon. There was a concert and smoker at the Coliseum for the men on Thursday evening.

Tuesday evening was given over to section dinners and entertainments and alumni reunions. During the past few years the latter have taken on great and increasing importance as an attraction for those contemplating attending the meetings of the association. This year the following alumni had reunions, all of which were well attended.

**Alumni College Reunions.**—Albany Medical College, Dartmouth Medical College, Detroit College of Medicine, Harvard Medical School, Jefferson Medical College, Johns Hopkins University Medical School, Kentucky School of Medicine, Long Island College Hospital, McGill University, University of Maryland, University of Michigan, University of Nebraska School of Medicine, Northwestern University Medical School, Medical College of Ohio, University of Pennsylvania Medical Department, College of Physicians and Surgeons, Chicago, College of Physicians and Surgeons, New York City, Rush Medical College, Tulane University Medical Department, Western Pennsylvania Medical College, Women Alumnae, Woman's Medical Society of Illinois, Medical Woman's Club of Chicago.

On Friday evening the Wiener Studenten 1906-07 enjoyed a Dutch lunch at the Tom Jones Restaurant. The Phi Rho Sigma Fraternity held a smoker on Monday evening at the Beta chapter house.

Opportunities were offered for members of the association to visit the plant of the Illinois Steel Company at South Chicago. Armour and Company, Swift and Company, and Libby, McNeill, and Libby arranged a demonstration of government inspection of meat and of the killing of cattle on Saturday morning, June 6th.

**The Scientific and Commercial Exhibits.**—The scientific exhibit, under the direction of Frank B. Wynn, of Indiana, was possibly not quite so large as that in Atlantic City, but was quite as interesting. Mention should be especially made of the exhibition of anatomical specimens from Tulane University and of the life history of the tick, *Dermacentor occidentalis*, and the pathology of Rocky Mountain fever.

The commercial exhibit was of the usual character.

There had been some doubt in the minds of some, in the East particularly, as to the possibility of hotel accommodations holding out; but no one, so far as we know, had any difficulty in securing satisfactory

quarters. The Chicago hotels which are opposite Grant Park on Michigan avenue have a site which is quite picturesque and is very interesting. To look out of one's window at night and to see three light-houses on guard at the entrance to the Chicago River, at the south end of the government pier, and at the crib for the intake of the Chicago water, one would easily imagine himself at the seashore. The Illinois Central Railroad is depressed so as not to spoil the view from the street, and when the road is equipped with electric locomotives there will be no telltale smoke to indicate its presence.

The meeting was a large one; up to Thursday at 4 o'clock 6,389 members had registered. The weather was all that could be desired.

### Proceedings of the House of Delegates.

The House of Delegates met on Monday, June 1st, at 10 a. m., the president, Dr. Joseph D. Bryant, of New York, in the chair.

After the adoption of the minutes of the fifty-eighth annual meeting the president delivered his annual address.

**The Retiring President's Address to the House of Delegates.**—Dr. Bryant spoke as follows:

Gentlemen: The period of my official connection with the high station to which I was chosen is drawing to a close, and in a few hours what yet remains will become a part of that already passed, when the whole will have been registered in the annals of the affairs of the organization, there to remain as evidence in the estimate of my official deserts. For the expression of confidence and respect so generously bestowed I again bow in most humble acknowledgment.

The practical wisdom of those who conceived and gave birth to the system of government of the association did not seriously contemplate that the transient advent of a president need much disturb the ordinary tide of its concerns. Whether or not this conception of presidential utility be wise or otherwise cannot yet be considered as settled. And, whether it be wise or not can better be determined by a broad spirit of statesmanship than by one of restricted policy. It might safely be regarded as possible that a transient judicious executive would exercise a wholesome influence in the control of affairs. Be this as it may, the comparative differences of the governing affairs of the association and those of the government on which they are fashioned become less apparent as one reaches the sources of authority, and they practically disappear at the port of the official head of this organization.

I am not finding fault because of this anomaly, but am simply pointing out what is recognized and gravely regarded by many thoughtful and devoted men, whose views are not limited by the horizon of the present time. In my judgment the well being of the association would be more securely fixed and correspondingly enhanced by requiring that the president cooperate with his colleagues in official labors, the same as is done in other corporate bodies of established significance.

The problem which for long has periodically perplexed our Federal government and its gracious and sympathetic people, viz., "What to do with the former presidents," now appears to be knocking at the door of expediency of our organization, and inquiring "What to do with the former presidents" of its own? In this connection, I would say that the degree of wisdom which our former presidents have acquired because of established official contact with their colleagues in the control of affairs cannot be seriously regarded as profoundly fitting them for much special consideration. With this important feature thus qualified, I am inclined to caution you to think carefully and act slowly in a matter which, while disturbing the equilibrium of con-

stituted State representation, seems not to contribute a commensurate gain.

I am aware it is often thought wise or expedient by some persons that the coordinating requirements of an organization be not too explicitly stated in its constitution and bylaws, but I am none the less of the opinion that these of ours could be improved in forms of expression and in scope and requirement by comparatively brief efforts of judicious character.

The fact of whether or not the provision relating to the calling of meetings is sufficiently amplified for the purposes of duly authorized action might well be determined.

The clause of the constitution providing that "no member of the House of Delegates shall be eligible to the office of president or vice president" is a wise and healthy measure, for men thus disposed should not be active constituents of a legislative body vested with the power of conferring official station, nor should one be thus connected whose remuneration for special services can come before the legislative body for consideration, for plainly obvious reasons.

The selection of the members constituting the special and reference committees of the session have been made, as far as practicable, in accordance with the numerical representation in the association of the respective parts of the country and as estimated for the purpose of selection by Mr. Hoffman, of Newark, a distinguished statistician and actuary. Therefore, if any disappointment should happen because of less representation than before, the difference is due more to the verdict of impartial figures than to the exercise of individual desire.

I have thus far on all occasions taken pleasure in commending the purpose and the work of the Council on Pharmacy and Chemistry. I again wish to renew this approval, and also to express the self evident fact that, if medical therapy is to be of reliable worth, then, indeed, the constructive purity of its agents and their physiological action must be scrupulously guarded.

I have been not a little disturbed by the assertions of persons who are engaged in the enterprises of pharmacy, related to certain wrongs which they claim to have sustained because of unfair and ungentlemanly treatment at the hands of responsible officials of the association. In one instance it was asserted that oppressive and illegal hardship had been inflicted which resulted in mental distress and in pecuniary loss. In this instance I expressed the belief to the complainant that he was in error, and predicted that the courts would so determine, were a test made, and advised that it be made at once. The complainant declined to accept this advice, saying that were his contentions well founded, and even sustained by the courts, still his business would be destroyed by retaliatory cooperative action of the members of the American Medical Association! Was ever an upright and independent body of men more misjudged than this? Could one impelled with childish imaginings be more mistaken than he? It were better far for the honor of the medical profession that this association resolve into thin air or into the sediment of a stagnant pool than thus attempt to smother established justice with the fumes of revengeful disorder. Already too much of this kind of spirit is abroad in the land for the comfort and security of law abiding people. And we, the members of a learned profession, should be ever actuated by the spirit of citizenship, which promotes good order in all things and invites the infliction of the penalties that foster obedience.

Bitter complaints have come to my notice which appear to embrace the practical question of whether or not those who are opposed to the policy of government which stands for the securing of trustworthy medicinal agents are entitled to the same consideration as are those who approve of and support the purpose. And, as a corollary of the preceding, whether or not those who actively give or passively lend support to a policy impairing or making uncertain the curative virtues of medicinal measures, or lowering in other ways the station of scientific medicine, are entitled for long to potent consideration at the hands of those who in this regard, are striving for the best of things. I do not understand how it is that this question can be answered in the affirmative. However, the unusual and novel questions which readily come to the front in these circumstances should be kindly thought firmly met, and with a spirit which, though striving for higher thought and action, neither, instead of needlessly provoking opposition.

I am convinced of the need, and commend to your approval the importance of the work being done by Dr. McCormack in elevating the tone and the standard of the

medical profession. A service of this kind is in order, and will enhance the station of medicine accordingly as the facts are wisely selected and judiciously expressed.

Some of the discreditable vagaries of thought and action that are noted in business relations are threatening to enter much into professional relations as well. In fact, tangible evidence is not lacking that practices of unethical reciprocal nature too frequently exist for the credit and honor of our calling. I regard it of special importance that students in medicine should have their ideas of professional conduct carefully moulded aright, while yet in the plastic state of development. The principles of moral philosophy as related to medicine are not apt to be decidedly catching in the instances of physicians whose thoughts and habits of action are already quite well established. And, also, the active and passive obstruction to coordinating within decent bounds certain questionable and convenient products of pharmaceutical skill are an earnest of the need for a proper bending of those who may be regarded as the "twigs" of our profession, so that as "trees" they later may be rightfully "inclined."

It would seem to me as wise that a standing committee on principles of moral philosophy as applied to medicine be constituted, with the view of elaborating still further ethical principles, and so far as practicable establishing in this respect uniformity between the medical profession of this and other countries. Also, I would suggest that undergraduate and postgraduate general instruction in ethical medicine be a part of the requirements of institutions engaged in medical teaching. I should expect greater, earlier, and more durable results, and without friction, from this plan than can come from any quasi-insistent method of endeavor. The incident of the insistent master, the abundant trough, and the unwilling horse well typifies the present situation in many instances. In any event, it would be well to properly develop the roots of our profession while busily trimming the branches.

I should signifyally fail in my duty at this time were I to omit telling you that plausible measures directed to the regulation of animal experimentation are abroad in the land, which are drawn so adroitly and presented so cleverly as to conceal, on confiding inspection, special factors of grave possibilities. Consequently, medical men who are loyal to the spirit of scientific endeavor are thoughtlessly giving strength to the stealthy foes of scientific medicine. It should not be possible to thus easily introduce into the ranks of our calling a wedge which, when driven home, would split our organization asunder on the policy of animal experimentation. Medical men should refuse to give assent to strange policies of a professional kind until after thoughtful and judicious consideration shall have determined the wisdom of the propositions. If organization in medicine stands for aught, it should stand for unity of purpose in all scientific matters relating to it. Since "forewarned is forearmed," each of you should keep in mind the possibility of besetting dangers, and in no instance fail to sound the alarm long in advance of parley or of impossible capitulation. I would respectfully urge that the House of Delegates take decided and far reaching action in this important matter.

Whether the constitution or the flag should take precedence in the outlying parts of our country need not concern this association as much as how soon can the medical profession of those accessions properly become integral parts of the organization. It seems to me that this question should be answered at the earliest practical moment. The claim of the medical profession of Alaska for similar action is one of substantial moment, and may be of superior importance to those of recent birth and of less development. The moral effect, on the tone of the profession of these communities, of the sympathy, approval, and support of this association, in the furtherance of proper methods of control of their affairs, would be encouraging to them and creditable to the organization. And no doubt the sooner the supporting hand is extended the easier and more complete will be their task.

In as brief manner as possible I have called your attention to certain things relating to matters of the organization which, in my judgment, should be better advanced in order to comport more closely with the standard of the affairs of organizations whose wisdom of government cannot paralyze. The question before the house is not how best to phrase a few, but how best to satisfy the sense. Therefore, the policy of government should be broad and uniform and in conformity with the wisdom of the

majority. Its conduct should be characterized by the inherent power of discriminating justice, patiently and temperately dispensed. The official servants of the organization should regard themselves as such, and not the masters of it. They should exercise discretion and patience, and consequently should be vigilant and gracious under all circumstances. And in this connection it should be remembered that our country is broad, and that its people are independent and honest; also that those of different parts of the country do not always think and judge alike in similar matters, and what is of special significance at this time is that the medical profession is an influential part of the people, and, therefore, of significant importance in its respective environments. I earnestly utter these words and without bias, because of the known recognized temptations to inconsistency of thought and action which the exercise of power so often begets. I would remind you that the wise exercise of power oftener requires greater skill and courage than does the achieving of power. And also that the absence of wisdom in control not infrequently destroys the highest governing conception of men.

Although it has been said that "those who think must govern those who toil," it should not be overlooked that, in a profession, those who toil must also think, and because of thought are competent to govern while yet they toil. That too much government is apt to be harmful is an accepted fact, and, therefore, that those who govern least may govern best cannot be gainsaid.

I should regard it as a misfortune were the duties of the House of Delegates of this association to become so onerous and perplexing as to eliminate from its councils men whose ceaseless toil makes for higher station in medicine. Consequently, I regard it as very important that the duties of this body be abridged and simplified as much as possible, and that judicious expedition in the conduct of its affairs be promoted and that hindering cavil be abrogated. When it shall appear that the uncertain products of legislative desire are of more concern than those of positive scientific endeavor, then the ennobling functions of the association will have been mortally hurt.

That "death has many doors to let life out" is the history of all bodies of men. And it is a matter of profound congratulation to us that, of the many doors in this organization, but few, indeed, came ajar during the last year. Through one, however, out into the unknown has recently passed a conspicuous member of the association and the profession—one whose indefatigable energy and ceaseless activity contributed enduring abundance to the honor and glory of our calling. In his profession, the paths which he hewed with consummate wisdom and patient care, often through obstacles akin to those of pious endeavor, still lead onward and upward and toward the terrestrial Mecca of cure and comfort of the human race. In other undertakings his footsteps were firm, consecutive, and direct, and his successes were indelibly impressed on the fields of his toil. And, as an example for emulation in all that relates to breadth of effort and height of success in the paths to which he clung, the memory of the late Dr. Nicholas Senn should be revered and ever regarded as a precious heritage of our profession.

An unprecedented incident of unusual significance and full of beneficent possibilities happened when, in March last, the President of the United States extended an invitation to the medical profession to take part in the conference on the conservation of natural resources. The President, in this regard, expressed himself as follows: "I wish to invite the cooperation of the American Medical Association in bringing this matter before the people; and it gives me added pleasure to invite you, as President of the association, to take part in the conference." It should not be necessary to say that I was present and that, on behalf of the American Medical Association, I thanked the President profoundly for the invitation, and pledged to his support in the conservation, not only the members of the American Medical Association, but the entire profession of the land. I would urge that prompt, appropriate, and decided action be taken by this body, thus showing appreciation of the invitation and determination to aid in every possible manner.

I should be negligent of a plain duty and the promptings of a keen sense of satisfaction were I to omit on this occasion to express my appreciation of the uniform courtesy which has been shown me by the members of this body and by the officers of the organization. The charm of official

association is greatly enhanced by the unanimity of purpose and the attention to duty which characterize those invested with responsibility. In this connection it can be truly said that criticisms visited on the officers of the association rarely include those of delay or indifference in the conduct of official business. And to have to do with the activity of an organization blessed with the chance of bringing the medical profession of this country into judicial unity, for the promotion of wise and beneficent purposes, is the distinction of a lifetime, and one which those who are thus favored should honor, as long as opportunity and effort can add to the glory and station of medicine.

Finally, the comforting optimism of my nature leads me to regard as certain the final success of all our contentions which are based on the capacity to gladden and to cure the afflicted of our kind.

The president appointed the following committees:

*Reference Committee on Medical Education.*—H. D. Arnold, Massachusetts (chairman); Frank Billings, Illinois; A. Vander Veer, New York; L. S. McMurtry, Kentucky; W. M. L. Coplin, Pennsylvania (Committee on Medical Education ex officio). *Reference Committee on Amendment to Constitution and By-Laws.*—George W. Guthrie, Pennsylvania (chairman); Charles E. Cantrell, Texas; G. L. Taneyhill, Maryland; C. H. Cook, Massachusetts; G. L. Strader, Wyoming. *Reference Committee on Section and Section Work.*—Leartus Connor, Michigan (chairman); S. W. Woodyard, Tennessee; Michael Hoke, Georgia; Julius Bierwirth, New York; Charles McVea, Louisiana. *Reference Committee on Rules and Order of Business.*—W. H. Sanders, Alabama (chairman); V. H. Stickney, North Dakota; J. F. Highsmith, North Carolina; J. N. Jenne, Vermont; Hugh F. Lorimer, Ohio. *Reference Committee on Legislation and Political Action.*—C. S. Bacon, Illinois (chairman); J. N. Hall, Colorado; S. Bailey, Iowa; Colonel H. G. Beyer, Navy; Major W. W. Ireland, Army (Committee on Medical Legislation, ex officio). *Reference Committee on Miscellaneous Business.*—Stuart McGuire, Virginia (chairman); J. B. McGaughey, Minnesota; H. H. McCarthy, Washington; J. T. Wilson, Texas; J. H. Pierpont, Florida. *Judicial Council.*—C. E. Cantrell, Texas (chairman); C. J. Kipp, New Jersey; J. F. Percy, Illinois; George Dock, Michigan; H. L. Alkire, Kansas. *Reference Committee on Reports of Officers.*—Wisner R. Townsend, New York (chairman); Donald Campbell, Montana; W. T. Williamson, Oregon; W. T. Sarles, Wisconsin; Frank Paschal, Texas. *Reference Committee on Hygiene and Public Health.*—W. N. Wishard, Indiana (chairman); A. R. Craig, Pennsylvania; G. B. Young, U. S. P. H. and M.-H. S.; J. D. Griffith, Missouri. *Committee on Credentials.*—H. B. Ellis, California (chairman); Horace Bonner, Ohio; C. M. Nicholson, Missouri; D. C. Brown, Connecticut; Adam Guthrie, Arkansas.

**Report of the General Secretary.**—Dr. GEORGE H. SIMMONS reported that on May 1, 1907, the membership in the American Medical Association was 27,515. During the year there had been a total loss of 2,344 members and a total gain of 6,172 members, so that on May 1, 1908, the total membership was 31,343, a net gain of 3,828. In September, 1907, the president appointed the following Committee on Nomenclature and Classification of Diseases: Dr. Frank P. Foster, of New York,

chairman; Dr. W. A. N. Dorland, of Pennsylvania; Dr. Victor C. Vaughan, of Michigan; Dr. Alexander Duane, of New York, and Dr. J. Chalmers Da Costa, of Pennsylvania.

Dr. William H. Welch resigned as a member of the Committee on Medical Legislation, and Dr. John B. Roberts, of Pennsylvania, was appointed by the president to fill his unexpired term.

Delaware and Maryland voted in favor of establishing branch associations; Colorado, Idaho, Massachusetts, New York, Rhode Island, Ohio, and Pennsylvania voted against their establishment; and twenty-five States have not yet voted on the question.

The secretary recommended that the entire matter of uniform regulations regarding membership be referred to a committee of three, at least two of whom should be secretaries of constituent State associations, with instructions to secure data regarding the present provision of the constitution and by-laws of various State associations on these points—as well as the procedure followed by State and county secretaries, and to report its findings and recommendations at the next annual session.

A number of communications had been received concerning the establishment of constituent associations in Puerto Rico and Alaska; but no such association had yet been organized.

*The American Medical Association Bulletin* was the continuation of the *Councillors' Bulletin*. It had been used for the distribution of the outline of post-graduate study, for information issued by the Committee on Medical Legislation, and a number would soon be issued containing the minutes of the conference on Medical Education, held in Chicago in April.

An invitation had been received for the American Medical Association to appoint two of its members to represent it in the council of the American Association for the Advancement of Science.

The past year had been one of increasing and unprecedented activity. Much good had resulted from the work of Dr. J. N. McCormack, of Kentucky, in the systematic organization of county and State societies.

**Report of the Board of Trustees for the Year 1907.**—The Board of Trustees presented the report of the Investors' Audit Company, of Chicago, which had audited the books of the various officers and committees of the association. This report showed an excess of \$94,650.15 over liabilities.

The treasurer had a total of \$89,118.84 in his hands on January 1, 1908.

The percentage of physicians receiving the *Journal of the American Medical Association* varied in the different States from 75.1 in North Dakota, the highest, to 21.5 in Georgia, the lowest. In New York only 39.5 per cent. of the physicians belong to the association, while in Pennsylvania the percentage was 40.6.

The work on the *Directory* had consisted in keeping up the records relative to the graduates of individual medical colleges, the compilation of a biographical card index of all physicians, revision and corrections of the first edition material, and a circular letter inviting criticisms and suggestions.

The first edition of the *Directory* was issued at a net loss of \$18,427.14.

The trustees appropriated a sum not to exceed \$225 to secure certificates of awards and medals in addition to the customary appropriation for the Committee on Scientific Exhibit.

The Board of Public Instruction on Medical Subjects received \$1,800. Dr. McCormack received \$7,500 for his travelling and other expenses, \$600 of which was for the purpose of establishing the post-graduate course of study. The *Anæsthesia Commission* was awarded \$200.

The resolution of Dr. Peterson, of Michigan, authorizing that free copies of the *Journal of the American Medical Association* be sent to the members of the Association of Medical Librarians was not allowed, because the libraries to which these librarians are attached already received free copies of the *Journal*.

The suggestion of Dr. Marcy, of Boston, that \$5,000 be appropriated for the erection of a monument to Dr. N. S. Davis was respectfully declined on the ground that such a precedent should never be established.

The increase of clerical help for the Bureau of Medical Legislation would be supplied from the office of the *Journal*.

The trustees felt that the American Medical Association owed a debt of gratitude to Dr. J. N. McCormack for the great work that he had done in his special department.

The fifty-eighth annual meeting of the Association, held in Atlantic City, cost \$4,499.98.

The trustees commended the work of the Committee on Pharmacy and Chemistry, and the work done in the chemical laboratory.

Dr. Reid Hunt, of Washington; Dr. E. E. Hyde, of Chicago; Dr. George Dock, of Ann Arbor; Dr. Robert A. Hatcher, of New York; Dr. W. S. Thayer, of Baltimore, and Dr. S. Solis-Cohen, of Philadelphia, were selected as the committee to represent the Association at the next revision of the pharmacopœia, and \$100 was appropriated for its expenses.

Dr. David L. Edsall, of Philadelphia; Dr. J. A. Capps, of Chicago; Dr. R. A. Hatcher, of New York, and Dr. Otto Folin, of Waverley, were elected new members of the Council on Pharmacy and Chemistry.

Dr. Alexander Lambert, of New York; Dr. C. F. Hoover, of Cleveland; Dr. A. S. Taussig, of Denver; Dr. Charles G. Stockton, of Buffalo; Dr. John A. Witherspoon, of Nashville; Dr. John T. Halsey, of New Orleans; Dr. Alfred Stengel, of Philadelphia; Dr. George E. de Schweinitz, of Philadelphia; Dr. Henry A. Christian, of Boston; Dr. George Dock, of Ann Arbor; Dr. LeRoy Crummer, of Omaha; Dr. H. C. Moffitt, of San Francisco; Dr. J. L. Miller, of Chicago; Dr. A. T. McCormack, of Bowling Green, and Dr. L. E. Barker, of Baltimore, were elected members of a staff of clinical consultants to the Council on Pharmacy and Chemistry.

The business affairs of the *Journal* office were in satisfactory condition, so that the office had no part in the "financial machismo."

The trustees suggested the advisability of making

an annual appropriation of \$500 for an essay on subjects relating to internal medicine; that this be awarded as a single prize, or as a first and second prize of, say, \$300 and \$200. They further suggested that, if this should be adopted, the editorial board of the *Archives of Internal Medicine* should have the management of the award of this prize or prizes.

They recommended the following amendment to the by-laws:

Amend Book I, Chapter III, of the By-laws by adding the following as Section 9: "Retired members": "Any one who has been a member in good standing of the American Medical Association for twenty years, and who has been placed on the retired list of his State association, shall, on his request, be placed by the secretary of the A. M. A. on the retired list of the members of this association. Retired members shall be exempt from the payment of dues."

**Report of the Committee on Medical Legislation.**—Dr. C. A. L. Reed, of Ohio, said that the Committee on Medical Legislation had endorsed the bill for the reorganization of the Army Medical Department, which became a law on April 23, 1908. The committee cooperated in every possible way with the Medical Department of the United States Army. It endorsed a bill reorganizing and increasing the efficiency of the hospital corps of the United States Navy; a bill authorizing the appointment of dental surgeons in the United States Navy; and a bill authorizing the establishment and organization of a corps of trained women nurses. None of these bills passed.

It endorsed the bill for increasing the pensions of Mrs. James Carroll and Mrs. Jesse W. Lazear, which passed.

The question of uniform and adequate State legislation on subjects pertaining to the practice of medicine and preservation of public health became more important each year. The policy of the committee was to cooperate with various State associations and the State legislative committees appointed by them; to outline uniform policies regarding the various questions involved; to draft and perfect model laws for the use of State associations; to accumulate, tabulate, and distribute necessary information regarding legislation in the various States, as well as in foreign countries, and to constantly aid the various State associations by advice and cooperation. The actual work of securing the adoption of desired laws should devolve on the State association and its legislative committee. In accordance with this plan, the committee had been working along three different lines, viz.: (1) The accumulation of data regarding medical practice acts; (2) the formulation of a model bill regulating vital statistics; (3) the collection of material regarding pure food and drug acts.

In order to accumulate data regarding medical practice acts the committee was engaged in making a comparison and analysis of the existing medical practice acts; in compiling a history of medical legislation; in compiling and comparing the medical practice acts of foreign countries; and compiling, collating, and comparing the decisions of all courts of final jurisdiction, both State and Federal, so far as they related to the constitutionality, interpretation, and enforcement of medical practice acts. It was obviously useless to attempt to draft a satisfac-

tory law for adoption by the different States without first knowing what the decisions of our courts had been on previous laws, and what rulings and interpretations would be sustained by the courts in future.

By the time the various State legislatures assembled in the fall, it was hoped to have a vital statistics bill ready for submission, which would have the endorsement of all the authorities on this subject as well as of all recognized organizations interested in this matter.

The committee had endorsed the pure food laws of Kentucky and Tennessee, two of the best State laws yet adopted, and with the national Food and Drugs Act and the Iowa law, comprised the best examples of pure food legislation.

During the past year the legislature had been in session in fifteen States. Through the Bureau of Medical Legislation the committee had endeavored to cooperate with the legislative committees of the various States and to afford them every possible assistance in securing the passage of good laws and the defeating of pernicious ones. The results had been most gratifying and encouraging. With the exception of the New York optometry law, which was now in the hands of the governor, not a single objectionable bill had been passed. On the other hand, the medical practice act of Kansas had been strengthened by the adoption of an amendment defining the practice of medicine, the legislature of Kentucky had passed one of the best pure food laws yet enacted by any State; a new board of health law was adopted in New Jersey; an important amendment to the medical practice act was passed in South Carolina, while in Ohio a record for a successful legislative campaign was established by the passage of a pure food and drug bill, a bill providing for county tuberculosis hospitals, a vital statistics bill, and a number of others. Bills intended to hamper animal experimentation had been defeated in New York and New Jersey. An excellent law establishing a Board of Health had been passed in Virginia.

At the Conference on Medical Legislation the resolution on the control of rabies, submitted at the last meeting by Dr. R. C. Cabot, of Massachusetts, was discussed. Resolutions were adopted favoring the increase of the scope and power of the United States Public Health and Marine Hospital Service, in order that the question of rabies and similar questions affecting the public health might be taken up by this service. The committee asked that the House of Delegates recommend to the various State associations that a State committee on legislation and public policy be established, if this had not already been done, and that the chairman of such committee be appointed by the president as the member of the National Council on Legislation for that State; that the House of Delegates further recommend that each association provide for an auxiliary legislative committee, consisting of one member from each county society, this member also to be appointed the member of the National Auxiliary Legislative Committee for that county.

It further recommended that Section 5, Chapter X, Book 3, page 20, of the Bylaws be amended by substituting the title "National Auxiliary Legis-

lative Committee," in place of "National Auxiliary Congressional Committee," as at present.

**Report of the Council on Medical Education.**—Dr. A. D. BEVAN, of Illinois, reported that the third annual conference of the Council for Medical Education was held in Chicago, April 13, 1908. This council was the instrument of the association in matters pertaining to medical education; its functions were those of a national bureau of information: it sought to collect the facts in regard to medical education in this country and abroad, and to give publicity to these facts. During the past year the work of the council had been continued along these lines, and the accumulation of data seemed to point to the following basic principles for a model medical practice act which should be agreed upon and adopted in each State: (1) A single licensing board made up of members irrespective of schools, the only requirement being that the men should be qualified practitioners of modern scientific medicine. (2) This board should have the power to determine the matter of preliminary education and medical curriculum and should have the power to refuse recognition to disreputable medical schools. (3) The preliminary education should be a standard four year high school education, to which should be added in each State, as soon as conditions warrant, a thorough training in physics, chemistry, and biology, including laboratory work. (4) A four year medical curriculum should be required, each annual session consisting of thirty weeks, thirty hours a week, the first two years to be spent in well equipped laboratories of anatomy, physiology, bacteriology, pathology, and pharmacology, officered by trained teachers; the second two years devoted to medicine, surgery, obstetrics, and the specialties, largely in clinical work in well equipped laboratories, dispensaries, and hospitals. (5) When conditions warranted, there should be added to this a compulsory year as a hospital interne. (6) The State boards of each State should inspect its schools and refuse recognition to those which were not teaching scientific medicine.

Then there should be a single association of State licensing boards organized, which should consist of delegates who were active members of State boards, representing every State in the Union. In order to secure better conditions there should be an active, earnest cooperation in each State between the State licensing board and the organized medical profession; and the profession must see to it that the necessary laws were secured and that efficient men were appointed to see that they were enforced. The report then took up the conditions now existing in each State, from the viewpoint of the ideal law above indicated. Then the defects were indicated, and the remedy, higher preliminary requirements, was pointed out. The report then gave an interesting collation of facts about medical standards abroad. Several diagrams and maps were shown which illustrated graphically the differences in standard of educational requirements in different countries and different States; both preliminary educational requirements and professional educational necessities. The recognition of medical colleges was taken up, together with reciprocity, progress toward uniformity, inspection of medical colleges, medical college mergers, and several other

important points which had a bearing on the subject of medical education. A special committee, composed of Dr. Victor C. Vaughan, of Ann Arbor; Dr. William J. Means, of Columbus; and Dr. George W. Webster, of Chicago, had been at work on an outline of what should constitute a medical college in good standing or a medical college which, in the light of present day medicine, should be considered as doing satisfactory work. The report of the committee outlined a schedule of minimum requirements, laboratory facilities, and clinical facilities which should obtain in a medical college before it could be considered to give a satisfactory course or be determined to be a medical college in good standing. This included requirements for matriculation, acceptable credentials, requirements for the course and for graduation, equipment and teaching facilities, and the conduct of the college.

**The Report of the Board of Public Instruction on Medical Subjects.**—Dr. JOHN G. CLARK, of Philadelphia, presented the report of the newly constituted Board of Public Instruction. The board had decided that the first articles that should appear under its auspices should be devoted to preliminary education. The public was to be instructed on the history of our present knowledge of infectious diseases. The board had decided that gynecological subjects and matters pertaining to sexual questions could best be taken up through circular letters to physicians or by carefully prepared monographs by some first class authority in the medical profession. In order to avoid the imputation of advertising, no allusion to the details of treatment should be included in these articles. The board had not decided whether such articles should be signed.

Dr. R. MAX GOEPP, of Philadelphia, had been selected as the salaried secretary of the board. The board recommended two lecture systems, one under the direct authority of the American Medical Association, which should be national in character, and one under the auspices of county medical societies. The board further advised the establishment of State boards of public instruction under the auspices of the various State medical societies. Both the State boards and the county boards should, of course, work in harmony with the national board. It was suggested that a brief epitome of articles be sent to the medical profession, either through the *Journal of the American Medical Association* or through a separate leaflet accompanying that journal. A provisional programme was submitted with titles of proposed articles under the head of medicine, including bacteriology, nervous diseases, surgery, hygiene, and the history of medicine.

**Report of the Committee on Organization.**—Dr. J. N. McCORMACK, of Kentucky, outlined the work of the year, which had been devoted principally to the making of addresses before audiences composed of laymen and physicians. He asked to be relieved of further duty on the Committee on Organization. The organization was so far completed that he deemed it unnecessary to devote his entire time to it; but he recommended that suitable men be kept in the field and that these men be increased in number as the necessity occurs.

**Report of the Director of Postgraduate Work.**—Dr. JOHN H. BLACKBURN, of Kentucky, said that an outline of study which was submitted to the American Medical Association at its Atlantic City meeting in 1907 had been sent out to selected workers in the profession all over the country for suggestions and criticisms. In the answers received particular attention was called to the necessity for instruction in materia medica and therapeutics. The first year's outline was published in two parts, each covering the work of six months. He had corresponded with the county society officers and with individuals in thirty-nine States regarding the course, and he had been notified of its formal adoption by ninety county societies. Five physicians had been following the outline as a reading course of home study because they were unable to meet with others as a club. The first year's programme consisted of twelve general subjects, but the second year's outline would consist of ten only. It was suggested that all societies intending to take up the course for the coming year should begin work the first week in September, so that the courses all over the country should be uniform. This second year's outline would be ready for distribution by August 1st. The committee had in view regular quarterly examinations, with proper credits and a certificate or a diploma on the completion of the four years' course. The object of the course in postgraduate study was the perpetuation of the county society and its active cooperation with the national society.

**The Report of the Committee on the Section in Tropical Medicine.**—Dr. L. HEKTOEN, of Chicago, reported that the committee regarded the formation of a section in tropical medicine by the American Medical Association as unnecessary at the present time. Papers and discussions on subjects connected with tropical medicine might be very well presented in the already existing sections. The report was adopted.

**The Report of the Committee on Scientific Research.**—Dr. ALFRED STENGEL, of Philadelphia, said that the following grants had been made by the committee for the encouragement of scientific research. The papers resulting from these grants were to be presented at the present meeting in Chicago:

Dr. D. J. McCarthy and Dr. M. K. Myers, of Philadelphia, An Experimental Study of Cerebral Thrombosis. Dr. Karl Voegtlin, of Baltimore, Chemistry of the Parathyroid Glands. Dr. Isabel Herb, of Chicago, A Study of the Ætiology of Mumps. Dr. R. M. Pearce, of Albany, Dr. H. C. Jackson, and Dr. A. W. Elting, A Study of the Elimination of Inorganic Salts in a Case of Chronic Universal Edema of Unknown Ætiology with Apparent Recovery. Dr. H. C. Jackson, Dr. C. B. Hawin, and Dr. H. P. Sawyer, A Comparative Study of the Physical Changes in the Blood in Relation to Opsonic and Phagocytic Indices and Cell Contents under Normal Conditions. Dr. H. T. Ricketts, of Chicago, An Investigation of the Identity of the Rocky Mountain Fever of Idaho with That Found in Western Montana.

The amount of the grant in each case had been fixed at \$200. The committee requested that its appropriation be increased to \$1,000 a year.

**Report of the Committee on the Davis Memorial.**—Dr. HENRY O. MARCY, of Boston, reported slow progress. Massachusetts had collected over \$700, but beyond this subscriptions had not been received. A number of the members of the committee had resigned, and the committee requested that it be given power to fill vacancies.

**Report of the Committee on Nomenclature and Classification of Diseases.**—Dr. FRANK P. FOSTER, of New York, said that he had communicated with Dr. Cressy L. Wilbur, chief statistician of the Division of Vital Statistics of the Bureau of the Census; with Dr. A. T. Bristow, of New York; with Dr. Wilmer R. Batt, of Harrisburg, representing the American Public Health Association, and with Dr. Robert L. Dickinson, of Brooklyn, representing the American Gynecological Society. As a result they recommended the adoption of the following resolutions:

1. *Resolved*, That the Nomenclature of Diseases of the Royal College of Physicians of London be recommended for the present use of American physicians in naming diseases and injuries in clinical reports and papers, morbidity and hospital returns, and for certificates of cause of death.

2. *Resolved*, That the International Classification of Diseases and Causes of Death be recommended for all official mortality and morbidity statistical reports.

3. *Resolved*, That the Committee on Nomenclature and Classification of Diseases present a report on the London nomenclature to the association at its meeting in 1909, with such recommendations as may seem advisable for American usage, and with the assignment of each term indicated according to the International Classification.

4. *Resolved*, That a tentative reconstruction of the International Classification be framed on the basis of the foregoing report, and recommendations be drafted for submission to the International Commission of Revision.

5. *Resolved*, That inquiry be made as to the possibility of holding the next Decennial Revision of the International Classification at Washington in 1910 in connection with the International Congress of Hygiene and Demography.

6. *Resolved*, That after the revision of the International Classification in 1910, the Nomenclature of Diseases be recast in corresponding form, so that there will be available under a uniform arrangement and with precise agreement in the meaning of terms:

- (1) International Classification of Causes of Death.
- (2) International Classification of Sickness and Disability.
- (3) International Nomenclature of Diseases and Injuries.

**Report of the Committee on Ophthalmia Neonatorum.**—Dr. F. PARK LEWIS, of New York, said that three things appeared to be necessary. (1) Exact data concerning the incidence of the disease and its results should be secured in every State. (2) The control of the disease rested with the State through its department of public health. (3) The securing of united and concurrent action for its control on the part of all those who know what to do and were willing to aid in stamping out the disorder. A circular letter had been addressed to the president and secretary of each State medical society asking that these three things be done. Gratifying answers had been received. The subject had been presented before a number of national societies. It was suggested that midwives be registered and that the disease be made reportable. An outline of the manner in which the problem might receive solution was appended to the report.

### Reports of Committees on Referred Business.

—It was deemed advisable that the services of Dr. J. N. McCormack be not entirely dispensed with, but that he remain as the directing officer of organization, even if he did not give his entire time to the work.

The report of the Board of Public Instruction was adopted, and the board was given power to have the articles that it intended to publish signed at its discretion.

The report of the Committee on Ophthalmia Neonatorum was adopted, and the committee was continued.

The report of the Committee on Scientific Research was adopted.

The report of the Committee on Nomenclature and the Classification of Diseases was adopted, and the committee was continued.

The report of the director of Postgraduate Study was adopted.

Changes in the constitution and by-laws.—The orations were made not mandatory, and authority was given that they might be delivered at section meetings if considered advisable.

### Report of the Reference Committee on Amendments to the Constitution and By-Laws.

—The committee reported adversely on the amendment to the constitution offered by Dr. J. N. McCormack, of Kentucky, to make the ex-presidents of the association members of the House of Delegates.

### Report of the Committee on Awards.—The

Committee on Awards, composed of Dr. William M. L. Coplin, of Philadelphia; Dr. George Dock, of Ann Arbor; and Dr. George W. Crile, of Cleveland, made the following awards to those exhibiting in the Scientific Department: The gold medal for a research exhibit of tick fever to Dr. H. T. Ricketts, of Chicago; a diploma for an exhibit illustrating the pathology of peptic ulcer, to Dr. Fenton B. Turck, of Chicago; a diploma for a teaching exhibit illustrating morbid anatomy, to the Northwestern University Medical Department; a diploma for a teaching exhibit illustrating morbid anatomy, to the Rush Medical College; a diploma for an exhibit of drawings of the human eyeground, to Dr. Charles H. Beard; a diploma for the exhibit illustrating early human embryology, to Dr. Maxmillian Herzog, of Chicago; a diploma for a clinical and pathological exhibit of stereoscopic photographs, to St. Mary's Hospital, Rochester, Minn.; a diploma for an improved method for the preservation and exhibition of anatomical specimens, to Dr. Edmond Semonin, of New Orleans; a diploma for an exhibit illustrating blastomycosis, to Dr. A. M. Stober, of Chicago; a diploma for an exhibit of drawings and photomicrographs illustrating the classification of tumors, to Dr. Mallory and Dr. Woolbach, of Harvard University. Honorable mention was made of the following exhibits: That of the United States Public Health and Marine Hospital Service, illustrating the investigations of Dr. C. W. Stiles, on hookworm disease; to the Iowa State University, for an instructive tuberculosis exhibit; to the Cincinnati Hospital, for a creditable group of speci-

mens; to the Philadelphia Polyclinic and College for Graduates in Medicine, for a creditable exhibit of a group of teaching specimens; to the Lying-In Hospital, of New York, for a creditable exhibit.

**Election of Officers.**—The following officers were elected for the coming year: President, Dr. William C. Gorgas, of the United States Army. Vice-presidents, Dr. T. J. Murray, of Butte, Mont.; Dr. John A. Hatchett, of El Reno, Oklahoma; Dr. Thomas A. Woodruff, of Chicago; Dr. E. N. Hall, of Woodburn, Kentucky. General secretary, Dr. George H. Simmons, of Chicago. Treasurer, Dr. Frank Billings, of Chicago. Trustees to serve until 1911, Dr. Wisner R. Townsend, of New York; Dr. Philip Mills Jones, of San Francisco; Dr. W. T. Sarles, of Wisconsin. Chairman of the Committee on Transportation and Place of Session, to serve three years, Dr. M. L. Harris, of Chicago. The following honorary members were elected: Professor E. A. Schaefer, of Edinburgh, Scotland; Dr. August Martin, of Greifswald, Germany; and Dr. E. Treacher Collins, of London. The president appointed Dr. Charles Harrington, of Boston, a member of the Committee on Legislation, to serve until 1911, and Dr. Victor C. Vaughan, of Ann Arbor, to be a member of the Council on Medical Education, to serve until 1913.

The next meeting will be held in Atlantic City.

**Officers of the sections.**—*Section in Practice of Medicine:* Chairman, Dr. Joseph L. Miller, of Chicago; secretary, Dr. Wilbur Tileston, of Boston; delegate, Dr. George Dock, of Ann Arbor; orator in medicine, Dr. John B. McElroy, of Memphis. *Section in Obstetrics and Diseases of Women:* Chairman, Dr. Walter T. Manton, of Detroit; secretary, Dr. C. Jess Miller, of New Orleans; delegate, Dr. J. H. Carstens, of Detroit. *Section in Surgery and Anatomy:* Chairman, Dr. John C. Munro, of Boston; secretary, Dr. John F. Binnie, of Kansas City; delegate, Dr. Edward Ochsner, of Chicago; orator in surgery, Dr. Harvey Cushing, of Baltimore. *Section in Ophthalmology:* Chairman, Dr. Alvin A. Hubbell, of Baltimore; secretary, Dr. A. E. Bulson, Jr., of Fort Wayne; delegate, Dr. Thomas A. Woodruff, of Chicago. *Section in Laryngology and Otology:* Chairman, Dr. W. Sohler Bryant, of New York; secretary, Dr. G. E. Shambaugh, of Chicago; delegate, Dr. H. W. Loeb, of St. Louis. *Section in Nervous and Mental Diseases:* Chairman, Dr. D. M. Allen Starr, of New York; secretary, Dr. W. A. Jones, of Minneapolis; delegate, Dr. T. H. Weisenburg, of Philadelphia. *Section in Diseases of Children:* Chairman, Dr. Thomas S. Southworth, of New York; secretary, Dr. W. W. Butterworth, of New Orleans; delegate, Dr. R. B. Gilbert, of Louisville. *Section in Hygiene and Sanitary Science:* Chairman, Dr. J. H. White, of the United States Public Health and Marine Hospital Service; secretary, Dr. S. T. Armstrong, of New York; delegate, Dr. Charles Harrington, of Boston. *Section in Pharmacology and Therapeutics:* Chairman, Dr. Reid Hunt, of Washington; secretary, Dr. C. S. N. Habern, of Chicago; delegate, Dr. M. Howard Tussell, of Philadelphia.

**Meetings of Sections.****SECTION IN PRACTICE OF MEDICINE.**

CHAIRMAN, C. F. HOOVER, CLEVELAND, OHIO; SECRETARY,

COMBINED MEETING OF THE SECTION IN PRACTICE OF  
MEDICINE AND THE SECTION IN PATHOLOGY  
AND PHYSIOLOGY.

"SYMPOSIUM" ON TYPHOID FEVER.

**The Channels of Infection in Relation to the Suppression of Typhoid Fever.**—Dr. M. J. ROSENAU, of Washington, said that there was more typhoid fever in the country than there was in the city. The infection came to the city in the water, in the milk, in other varieties of food, and in the bodies of certain persons who were now known as typhoid fever carriers. The city returned the compliment to the country, but to a less extent. The water was the principal vehicle of infection, but not to such an extent as used to be imagined. There were two kinds of epidemics due to polluted water—the great epidemics, which were due to high pollution, and

epidemics of less intensity, due to a diluted or attenuated infection. In addition, there were the cases of residual typhoid fever which were due to other sources of infection. In Washington, in 1907, with a very good sanitary water supply, there were thirty-five deaths from typhoid fever to the 100,000 population. The author thought that probably twenty-five per cent. of these cases were due to milk and probably more than thirty per cent. to direct contagion. Typhoid fever might be uniformly distributed through a community without being due to any single cause, such as water. In a community in which typhoid fever was prevalent the normal curve of case incidence showed the greatest number of cases in the late summer and early autumn. In places in which typhoid fever was due to an infective water supply, the greatest number of cases occurred in the late winter and early spring. Milk was the second great channel of infection. In Washington, in 1906, eleven per cent. of the cases were traced to milk, and in 1907 nine per cent. of the cases were due to milk. The author considered that these figures were too low, because the only cases that could be traced were those that occurred in localized outbreaks. In a study of the dairies in Washington it was found that the number of cases of typhoid fever occurring in the families supplied by the different dairymen (the case incidence of typhoid fever to 100,000 gallons of milk supplied) varied from 6.7 among the customers of a man who sterilized his bottles and pasteurized his milk, to 52.5 among the customers supplied by a man who did neither. What the result would have been if all bottles had been sterilized and all the milk kept as clean as possible could only be imagined. In Glasgow, Liverpool, and London, however, there was a reduction of fifty per cent. in the case incidence of typhoid fever with the establishment of pasteurization of milk. All this reduction, however, could not be credited to this factor, because sanitary measures and filtration of the water supply were established at the same time. In order to secure a clean milk supply for a given community, it would be necessary to educate the farmers in methods of producing a clean milk, and it would be necessary to pasteurize the milk in addition. The third great source of infection was the so called typhoid carriers. In Washington, in 1906, six per cent. of the cases, and in 1907 nineteen per cent. of the cases, were shown to be due to contact. These figures were too low, because it was difficult to trace contacts. Typhoid fever was a contagious disease and should be isolated, and typhoid suspects should be isolated and thorough disinfection should be carried out. The investigations of Reed, Vaughan, and Shakespeare showed that typhoid fever was spread by actual contact. Children probably played an important part in the transmission of the disease, because the disease in children was very often atypical and abortive. In America the things to be desired for the prevention of typhoid fever were a clean water supply and an uninfected milk supply, isolation of the patients, and early diagnosis.

**The Value of Blood Culture in Typhoid Fever.**

Dr. FRANCIS W. PEARBODY, of Boston, said that the early diagnosis of typhoid fever was of great

importance on account of the possibility of spreading the disease by contact with the patient and by contact with the convalescent for a varying period after the disease was supposed to be cured. He referred to the obvious objections to the ordinary methods of making blood cultures. He mentioned the employment of ox bile as a culture medium for the *Bacillus typhosus*, and described a method of making a blood culture with blood obtained by the ordinary method of puncture. Two cubic centimetres of blood were inoculated into a small quantity of pure sterile ox bile, which was incubated for twenty-four hours. A portion of this culture was then transferred to Löffler's blood serum medium and incubated for another twenty-four hours. The isolation of a motile bacillus was presumptive evidence of the existence of typhoid fever, but, of course, further culture experiments were necessary to establish the identity of the organism. In the Massachusetts General Hospital fifty-five out of eighty-two cases of suspected typhoid fever were diagnosed by this method. The drawbacks to the Widal reaction, as an early diagnostic method, were the fact that the reaction was sometimes late in appearing and that it was not absolutely specific. As a supplement to a blood culture, however, the Widal reaction was very valuable, because the latter occurred late, and the former occurred early in the course of the disease.

**Typhoid Bacillus Carriers.**—A paper with this title, by Dr. WILLIAM H. PARK, of New York, was read by Dr. W. B. Cannon, of Boston, in the unavoidable absence of Dr. Park. After an attack of typhoid fever it was known that persons passed typhoid bacilli in the urine and in the feces for a varying period of time, sometimes for many years. The typhoid bacilli that were passed in the feces probably came from the gallbladder, although they might be multiplying in the folds of the mucous membrane of the intestine and in the glands of the intestine. Large numbers of cases had been traced to these bacillus carriers. Women were more frequently bacillus carriers than men. A cook who had lived in eight families in New York city, in seven of which cases of typhoid fever had developed after she had entered the service of the family, was referred to the laboratory of the New York City Department of Health. In these seven families twenty-six cases of typhoid fever had developed, with one death. Thirty per cent. of the bacilli in the feces of this woman were found to be *Bacillus typhosus*. The woman denied that she had ever had typhoid fever. The stools from fifty-two persons who had had typhoid fever in an epidemic in the New Jersey State Insane Asylum were examined, and two of them were found to contain *Bacillus typhosus*. The stools from sixteen persons in a Long Island village who had recovered from typhoid fever were examined, and two of them were found to contain *Bacillus typhosus*. In other words, six per cent. of the patients examined were found to have typhoid bacilli in their feces. There were numerous cases of typhoid bacillus carriers who had never had typhoid fever, but who had been exposed to the infection. Isolation in these cases was not always possible, although the woman first referred to was being detained by the Department of Health.

**Some Conditions Simulating Perforation in Typhoid Fever.**—Dr. DAVID L. EDSALL, of Philadelphia, said that he did not wish any of the remarks he was about to make to be construed as undervaluing the necessity for operation in cases of typhoid perforation, but he wished to point out that the tendency of the surgeon was to operate in any case in which a perforation was suspected. He thought that an operation during the course of typhoid fever was not a harmless procedure, and that every case should be carefully studied clinically before an operation was undertaken. Among the diseases which simulated perforation in typhoid fever was, first, acute, sudden, lobar pneumonia. He referred to three cases of this character which had occurred in his wards in the Episcopal Hospital in Philadelphia. Second, there was typhoid spine, which occurred during convalescence and might simulate typhoid perforation. Third came thrombosis of one of the iliac veins. Fourth, there was a marked, severe, stormy crisis, which was, of course, uncommon. He said that he thought that the surgeon had more faith in rigidity of the abdominal muscles as a sign of perforative peritonitis than was proper. If rigidity of the abdominal muscles was associated with a general muscular rigidity of equal intensity, the sign would lose much of its value as a symptom of typhoid perforation. A sharp and sudden fall of temperature near the end of a case of typhoid fever was likely to be followed by a relapse. A careful, complete physical examination, including the chest and the vertebral column, should be made in every case in which typhoid perforation was suspected. One should consider the general features of the case, and if the abdominal symptoms were not prominent enough, the patient should not be operated upon.

**The Metabolism of Typhoid Fever.**—Dr. P. A. SHAFFER, of New York, said that during an attack of typhoid fever the patient lost from ten to sixty pounds of his tissue. This loss was felt particularly in the fats and proteins. The excretion of acetone bodies in the urine in cases of typhoid fever ought not to occur if the patient received plenty of carbohydrate food. The loss of nitrogen was common in typhoid fever, and accounted for the wasting and the weakness. These symptoms were due in part to the destruction of tissue and in part to an autointoxication, not to a bacterial endotoxine. The causes for the loss of protein, during typhoid fever, were partial starvation, pyrexia, and the action of the toxins produced by the typhoid bacilli. The author described certain metabolism experiments which he had carried out in Bellevue Hospital. As a result of these experiments they were able to retard the loss of nitrogen by prescribing a diet which contained a moderate amount of protein and a large amount of carbohydrate, so that the caloric value of the food was kept high. The loss of protein might be compensated for only when 3,000 to 4,000 calories were given daily. It was quite possible to give with benefit liberal diets to patients suffering from typhoid fever. When such a diet was given, the patient had little or no tympanites and little fermentation in the intestines. The ordinary milk diet in typhoid fever deprived the patient of fifty per cent. of his normal nutriment.

**The Treatment of Typhoid Fever.**—Dr. THOMAS MCCREA, of Baltimore, said that it was necessary to study the individual patient with care, and to give him such a diet as would be suitable for him. He thought that the simpler the diet the better, and was inclined to adhere to the common milk diet. He said that there was need for large amounts of water in the treatment of typhoid fever, and it was his custom to give an amount that would cause the patient to excrete from one hundred to one hundred and fifty ounces of urine daily. This internal hydrotherapy, combined with external hydrotherapy, had been very useful. The composition of predigested foods should be investigated before they were used. The initial purge, he thought, gave a higher incidence of diarrhoea than when the bowels were let alone. Opium was rarely justifiable; in the majority of cases it caused harm. If restlessness must be treated, it was better to use morphine by the hypodermatic route. If diarrhoea was troublesome and required opium, it was better to use the starch and laudanum enema. In hæmorrhage in typhoid fever, the lead and opium pill ordinarily advised did harm. It favored distention and concealed the signs of perforation. Hæmorrhage was best treated with hypodermatic injections of morphine, a reduction in the diet, the local application of an ice bag, and the administration of calcium lactate in doses of thirty grains a day. In cases of perforation a more careful study of the signs and symptoms ought to be made. There should be more frequent and earlier consultations between the physician and the surgeon. As between the opinion of a surgeon who had seen a patient once and that of the physician who had carefully studied the case for a long period of time, the latter was the more valuable. In order to relieve gaseous distention of the stomach, the passage of the stomach tube was the method to be preferred. Urotropin was valuable in preventing bacilluria, and, if given in large enough doses, it would be found in all the fluids of the body. Thus it might kill any bacilli that were inhabiting the gallbladder. For this purpose he used as much as seventy-five grains a day, watching the urine for any sign of hæmaturia. The prevention of infection was as important as the treatment of the disease. In order to accomplish this, isolation of the patient, personal cleanliness of the physician, the nurse, and the orderly, the use of rubber gloves by the nurse, if she had to handle bed pans, urinals, and soiled bedclothing, were necessary. The nurse who handled typhoid fever patients ought not to handle other patients. The family should be instructed in these methods by written direction. The supply of bacilli in a patient who had had typhoid fever should be exhausted before he was discharged.

Dr. WILLIAM S. THAYER, of Baltimore, said that he agreed that typhoid fever was a contagious disease and that the sooner we realized it the better.

Dr. JAMES M. ANDERS, of Philadelphia, said that Dr. Rosenau had laid down a very important principle when he said that we should endeavor to discover the channel of infection in typhoid fever epidemics in each individual community.

Dr. JOHN A. WITHERSPOON, of Nashville, said that the physician should instruct the people in the methods of preventing infection with typhoid fever.

Dr. MUNSON, of Springfield, Ill., asked how long the typhoid bacillus would live in the ground.

Dr. ALEXANDER LAMBERT, of New York, said that it was important for county medical societies to undertake to certify the milk used in the districts over which they had surveillance.

Dr. ROSENAU said that it was difficult to take all the measures to prevent the occurrence of infection in a given individual, but that it was comparatively easy to diminish the amount of typhoid fever in a community.

Dr. JONES asked whether the color of the bile used for making blood cultures made any difference, and he also wished to know how fresh the bile should be.

Dr. PEABODY said that he had found no variation in the results when he had used dark green or golden yellow bile. After sterilizing, the bile kept indefinitely. He had obtained the same results by using pig's bile.

Dr. HENRY ALBERT, of Iowa City, referred to an epidemic of typhoid fever in Cedar Falls, Iowa, which had been traced to a bacillus carrier.

Dr. PHILIP MARVEL, of Atlantic City, spoke of the advisability of draining the gallbladder in the case of a bacillus carrier.

Dr. LITTERER, of Nashville, reported a case in which he had obtained a pure culture of *Bacillus typhosus* in the pus of a periosteal abscess three months after the abscess had been opened. He thought that such a patient should be considered a bacillus carrier. A typhoid vaccine had cured the abscess. He thought that a typhoid vaccine might be used in cases of infected gallbladder.

Dr. ROSENAU said that the gallbladder was not the only source of the appearance of typhoid bacilli in the faeces, and that draining of the gallbladder was probably not justifiable.

Dr. JOHN A. LIGHTY, of Pittsburgh, said that stone in the ureter and appendicitis might resemble typhoid perforation.

Dr. ANDERS said that in perforation of the intestine the temperature did not always fall. On the other hand, it frequently rose. Dulness in the flanks was not always due to perforative peritonitis. He did not base his diagnosis on any single symptom, but only on the combination of symptoms. The most common condition simulating typhoid perforation was excessive tympanites. This condition was frequently accompanied by movable dulness in the flanks.

Dr. EDSALL said that the absence of liver dulness and movable dulness in the flanks were not very valuable signs of intestinal perforation.

Dr. ALEXANDER LAMBERT, of New York, said that a liberal diet in typhoid fever prevented meteorism, delirium, and great losses of weight.

Dr. ELLIOT P. JOSLIN did not approve of giving typhoid patients such large quantities of water, nor did he think it was necessary to have the patient pass such large quantities of urine. He referred to the possibility of favoring the development of arteriosclerosis by this procedure.

Dr. THAYER said that the physician should have the surgeon see the patient when he first thought that an operation for perforative peritonitis might be necessary.

Dr. LITCHFIELD said that he approved of the initial purge.

Dr. H. P. FAVILL, of Chicago, said that he objected to lead and opium in the treatment of typhoid hæmorrhage, because they produced meteorism, obscured the symptoms of perforation, and locked up a large amount of blood in the bowels, where it had a tendency to decompose.

Dr. GEORGE DOCK, of Ann Arbor, said that he approved of the initial purge.

COMBINED MEETING OF THE SECTION IN SURGERY

AND ANATOMY AND THE SECTION IN LARYN-

GEOLOGY AND OTOTOLOGY.

The Lantern Slide Demonstration of Cranial

Technique.—Dr. HARVEY CUSHING, of Baltimore,

exhibited a number of lantern slides showing the

details of the methods employed in his clinic in in-

tracranial operations. He said that the surgeon

who wished to do brain surgery should endeavor

to perfect himself in neurology, and that the neu-

rologist who intended to direct intracranial opera-

tions should learn something about surgical tech-

nique. One of the most important questions

connected with intracranial surgery was that of the

administration of the anæsthetic. Disregard of the

risks of the administration of anæsthetics had been

well pointed out by Dr. John B. Roberts. These

risks were particularly prominent in brain surgery,

where the anæsthetist came in contact with the field

of operation and in which the induction of anæ-

sthesia was particularly difficult. He made a hood

for the anæsthetist with a sheet, and administered

the anæsthetic by the ordinary method of inhala-

tion. The anæsthetist listened to the patient's heart

continuously during the operation. He shaved the

scalp just before the operation, and arranged the

sheets and the towels, which were sometimes pinned

to the scalp itself, so as to expose as little beyond

the field of operation as possible. After the shav-

ing, the line of incision was scratched on the scalp.

He described the tourniquet and the forceps used

in his own operation. He then showed photographs

of the method and the results of decompressing op-

erations. If a decompression operation was fol-

lowed by internal hydrocephalus, that operation was

inefficient, and this complication was particularly

likely to develop in cases of cerebellar tumor. In

these cases, also, lumbar puncture was particularly

dangerous, because the pressure was exerted in such

a way that the medulla and the cerebellum were

forced down into the foramen magnum. After a

decompression operation the tumor sometimes be-

came localizable. A tumor which could not be lo-

calized was the most favorable for a decompression

operation. He said that he had done one hundred

decompression operations in three years. Decom-

pression was also of value in cases of uremia and

in cases of fracture at the base of the skull. He

then reported seventy-five cases of operation on the

Gasserian ganglion, with two deaths.

Dr. FRANK HARTLEY, of New York, exhibited a number of lantern slides illustrating the instruments used, the method of preparing the field of operation, the method of making the flaps, and the method of craniocerebral topography for operation on the various regions of the brain.

Dr. CHARLES H. FRAZIER, of Philadelphia, described his method of operating upon tumors of the brain. He said that he had operated in a number of cases of epilepsy within the last few years, and that a decompressing operation had given relief in many cases. On opening the skull in these cases he found that the dura mater was thickened, that it was adherent to the underlying membranes, and that there were lines of thickening along the cerebral vessels.

**Intracranial Complications of Diseases of the Eye.**—Dr. JAMES F. MCKERNON, of New York, said that pachymeningitis was indicated as a complication of a disease of the eye by the existence of headache which corresponded to the area of inflamed dura mater. This headache was aggravated by exercise and was frequently accompanied by delirium. The diagnosis of the condition was not usually made prior to the operation. When the existence of the disease was suspected, it was because of the character of the pain. In such a case every vestige of diseased bone should be removed at the operation.

Epidural abscess was usually found around the sigmoid sinus. It was indicated by headache and continuous high temperature, followed by stupor, chills, and an irregular temperature. If the diagnosis was made before the operation, it was made on account of the occurrence of tenderness on pressure and on percussion over the collection of pus and cedema of the soft parts over that collection. The polymorphonuclear leucocytes were found increased in number. In such cases all diseased bone should be removed. Thrombosis of the lateral or of the sigmoid sinus might be partial or complete. The cases might be typical or atypical, or they might occur as primary lesions of the bulb without disease of the mastoid. These cases were characterized by high and fluctuating temperature, chills in fifty per cent. of the cases, and chilly sensations in many of the others, a rapid pulse, corresponding to the temperature, pain along the course of the internal jugular vein, intraocular symptoms in one third of the cases, cedema over the mastoid bone, and stiffening and rigidity of the muscles of the neck. Except in advanced cases, the cerebral functions were normal. The vein would have a hard and cordlike feel. Bacteriological examinations of the discharge from the eye were of value; a distinctive blood count in which the polymorphonuclears were over eighty per cent., also, blood cultures were of importance in arriving at a proper diagnosis. The only treatment for this condition was a complete excision of the sinus.

**Intracranial Complications of Diseases of the Nose.**—Dr. C. G. COAKLEY, of New York, said that few rhinologists had had experience with intracranial disease complicating disease of the nose. When intracranial lesions did occur, the organisms entered the cranium along the lymph spaces or through the bloodvessels which drained into the cerebral sinuses, and a complete nasal examination

was often very unsatisfactory because of the common occurrence of nasal and nasopharyngeal catarrhs and other nasal lesions, such as polypi. When it was necessary to explore the accessory nasal sinuses, he preferred the ethmoidal route.

Dr. JOHN B. MURPHY, of Chicago, recommended ligation of the external carotid artery for hæmorrhage from the middle meningeal artery and other hæmorrhages about the skull. He exhibited an instrument for opening the skull and a probe pointed needle for exploring the brain after the skull had been opened. He pointed out the value of the cisterna magna for purposes of drainage, and referred to the necessity for removing a V shaped piece of velum for the purpose of preventing occlusion of the foramen of Magendie.

Professor JENSEN, of Berlin, said that purulent troubles within the skull were rare after disease within the nose; he had seen but three out of twelve hundred cases of nasal disease that developed meningitis as a complication; all of these patients died. He had had no deaths from abscess of the brain. He had seen patients with serous meningitis recover after the removal of pus from the labyrinth. An auditory tumor gave the symptoms of labyrinthine disturbance, and cerebellar abscess gave similar symptoms in some cases.

#### SECTION IN OBSTETRICS AND DISEASES OF WOMEN.

CHAIRMAN, WALTER B. DORSETT, ST. LOUIS; SECRETARY, W. P. MANTON, DETROIT.

Chairman's Address: Criminal Abortion in Its Broadest Sense, By WALTER B. DORSETT.

Prolapse of the Rectum and Sigmoid Flexure Following Hysterectomy, By L. J. HIRSCHMAN.  
The Adjustable Canvas Chair as an Aid in the Murphy Treatment of Diffuse Suppurative Peritonitis,

By D. TODD GILLIAM.

**Criminal Abortion in Its Broadest Sense.**—Dr. WALTER B. DORSETT, of St. Louis, used the above title for the address of the chairman of the section. He gave the results of the answers to the following questions submitted to a lawyer in St. Louis: First, in a case of criminal abortion is the woman guilty of any crime? In nine States the woman is guilty of felony; in seven States she is guilty of a misdemeanor; and in thirty-five States she is guilty of no crime. Second, what is the charge and what is the penalty for giving, selling, or offering for sale abortifacient drugs or instruments for the prevention of conception? In twelve States these constitute a felony, and the penalty varies from imprisonment to a fine ranging from \$50 to \$5,000; in twenty States it is a misdemeanor; and in thirty States there are no laws covering the subject. Third, what is the charge, and is the penalty dependent on the age of the fœtus? In four fifths of the States the age of the fœtus is immaterial. Fourth, what is the effect of the death of the woman as to the charge and the penalty after the production of a criminal abortion? In eighteen States the charge is murder, and the penalty is death or imprisonment for life; in six States the charge is murder in the second degree and the penalty is imprisonment for life or for not less than three years. Fifth, can the license of the offender be revoked after the production of a criminal abortion? In fifteen States it can be revoked; in thirty-two States there is no law. Sixth, can the physician who gives subsequent treatment in a case of criminal abortion be allowed to testify, or is his information regarded as a professional secret? In one State only is he allowed to testify. Dr. Dorsett called attention to the fact that the laws were insufficient or inadequate, and he advised the appointment of a committee by the House of Delegates, to be known as the Committee on Criminal Abortion, which should undertake to secure the passage of suitable law after

having studied the conditions from all points of view.

Dr. WATHEN, of Louisville, said that abortion was offensive to every honest doctor and every honest citizen. He considered that the offense was no worse for the woman than for the man who committed it. In his opinion the offense was just as great four weeks after conception as eight months after.

Dr. CARSTENS, of Detroit, said that in this country people had not grown morally as they had financially. The question of the prevention of abortion was a question of education of the people in their moral responsibility. It was also a question of the education of girls in the meaning of life and the duty of maternity. It was the duty of the medical profession to teach, in so far as the opportunity lay with them, this moral responsibility, and also to teach the necessity of love for children.

Dr. HELEN PUTNAM, of Providence, said that for the last year she had been investigating the teaching of physiology and hygiene in the public schools, and incidentally she had been inquiring into the method, if any, by which the question of sex was treated. She found that many teachers, particularly those who had had a training in biology, were doing admirable work in teaching the phenomena of life, especially as illustrated by plants and the lower animals. They compared the facts thus presented to their pupils with the facts of the development of human beings, and finally gave their pupils a talk on sexual matters. She was of the opinion that in this manner the young people of the country might be brought in time to have a proper idea of the sex problem, and thus the tendency to the production of criminal abortion would gradually be checked.

Dr. R. W. HOLMES, of Chicago, said that for the last year or two he had been the chairman of the committee of the Chicago Medical Society which had had the question of criminal abortion under consideration. This committee found that the public did not want a campaign against criminal abortion. In Illinois legislation was not needed; the necessary endeavor was toward the enforcement of the existing law. He said that we must go back and educate the boy and the girl in the meaning of conception.

Dr. ABRAMS, of Michigan, said that he had been a member of the Michigan legislature and the chairman of its Committee on Public Health. He said that there was no more prolific cause of the production of abortion than making the woman a party to it, because it was then impossible to obtain evidence.

Dr. HENRY said that it was necessary to instruct the people in the physical evils of abortion and to teach the moral side of the question.

Dr. DENSLOW LEWIS, of Chicago, emphasized the need of education of the young concerning the sex relationship.

Dr. A. MARTIN, of Greifswald, Germany, condemned criminal abortion, but said that any law passed to control it would fail.

Dr. DENSLOW, of Chicago, said that it was easy to get a law, but difficult to enforce it. Among the poor there was no need for preaching about the subject. Among the rich, child-birth was frequently an

convenient, and it was necessary that these and the moderately well to do should be educated on all sides of the question. She thought that the man should be made equally to blame with the woman whenever blame was to be placed. She thought it was very important to teach the people the responsibility that they bore to the unborn.

Dr. LAWRENCE, of Cincinnati, said that, in his opinion, it was necessary to teach the meaning of the term viability. He offered a resolution asking the House of Delegates to begin to educate the people concerning these matters. The resolution was carried.

Dr. DORSETT agreed that the education of the laity was important, but he emphasized the necessity for the passage of uniform laws covering criminal abortion in all of the States and Territories.

Dr. FREDERICK, of Buffalo, offered a resolution referring the entire matter to the House of Delegates, and requesting them to appoint a National Committee on Criminal Abortion. The resolution was carried.

Curative Effect of Rest in Children with Persistent

Loss of Appetite,

By IRVING M. SNOW.

**The Prephysical Signs of Tuberculosis.**—WILLIAM C. HOLLOPETER, of Philadelphia, called attention to the insidious onset of tuberculosis in children, many cases resulting from a previous acute infection, such as pneumonia, measles, or whooping cough. The mediastinal lymphnodes were frequently the earliest involved of all the lymphnodes, and a recognition of the existence of these enlarged nodes was an important point in early diagnosis. The signs of pressure on the veins, dullness over the first piece of the sternum, and paroxysmal cough were important symptoms of this condition. The development of a venous hum heard over the first part of the sternum when the child's head is bent back so that its face was almost horizontal was an important physical sign of enlargement of the mediastinal lymphnodes and of early tuberculosis. The detection of enlarged mesenteric lymphnodes and the demonstration of tubercle bacilli in the rectal mucus were two other important methods of determining the existence of latent tuberculosis.

**Chronological and Anatomical Age.**—Dr. THOMAS MORGAN ROTCH, of Boston, said that the age of a child in years did not give a proper idea of the anatomical development of that child. For the past several years he had been studying the anatomy of children by the aid of skiagraphs, and he found that the development of children was very frequently six months or a year behind the degree that was considered by most authorities to be normal. He showed the bearing that these facts would have upon school work, athletics, and child labor. He divided his cases into a number of groups, depending upon the degree of development of the centres of ossification in the bones of the hands and wrists. The paper called forth considerable interesting discussion by a number of well known pædiatrists.

**A Study of the Anæmias of Infancy.**—Dr. JOHN LOVETT MORSE, of Boston, described the characteristics of the blood in infancy, and the changes in the blood picture dependent upon the age of the patient. In children the hæmoglobin was relatively low and the lymphocytes were increased in numbers. He said that chlorosis did not exist in infancy, although anæmias of the chlorotic type were common. He said that pernicious anæmia was very rare in childhood, but that when it did occur it was almost always of the metaplastic type. Secondary anæmias were very common and were frequently associated with enlargement of the spleen. He thought that there was no justification for placing cases of anæmias with splenic tumor in a class by themselves with a special name. Leuchæmia was very rare during childhood, but when it did occur, almost all of the cases were acute, and the majority of them were of the lymphatic type.

 Neuromuscular Coordinations Having Educational Value, By LUTHER H. GULICK.

The Use of Physical Measures in the Therapeutics of the Nervous System, By WILLIAM BENJAMIN SISK.  
 Rontgenology in Neurology, By MIRIAM K. KASSABIAN.

Chairman's Address: Neurological Teaching in America.—Dr. T. H. WEISENBURG, of Philadelphia, traced the development of neurological and psychiatric teachings in America from the time of Rush's lectures in Philadelphia in 1791. No lectures on the subject of neurology were given until 1867, when Dr. William A. Hammond, one of the former editors of the *New York Medical Journal*, began his course on the diseases of the nervous system in the Bellevue Medical College in New York. In 1871 Dr. Hammond's book on *Nervous Diseases*

appeared. Dr. Weisenburg then referred to the lectures given by E. C. Seguin in New York; the work of Mitchell, Moorehouse, and Keen in Philadelphia; of Putnam, Bowditch, and James in Boston; of H. C. Wood in Philadelphia; of J. S. Jewell in Chicago. He referred to the first course of lectures in electrotherapeutics, which was given in New York as a department of neurology in 1875 by Neftell, Beard, and Rockwell, followed by the course given by Mills, in Philadelphia, in 1877.

In psychiatry, after the lectures of Rush, no course was given until in 1867, when Dr. William A. Hammond began to give a course of lectures on insanity in the Bellevue Hospital Medical College. Dr. Isaac Ray was appointed lecturer on insanity in the Jefferson Medical College in Philadelphia, an appointment which was preceded by the publication of the *Medical Jurisprudence of Insanity* in 1838.

In discussing the methods employed at the present time in the teaching of neurology in the medical schools of America, the courses at Harvard, Cornell, Pennsylvania, and Northwestern were compared as four examples out of the many excellent courses given. In comparing the methods employed in teaching in this country with those in use in the leading schools of Europe, the American schools were far ahead of the latter in their undergraduate courses in neurology and psychiatry.

The author then discussed the postgraduate teaching of these subjects, beginning with the foundation of the New York Polyclinic, in 1881, and the Philadelphia Polyclinic and College for Graduates in Medicine, in 1882. He then outlined a course particularly fitted for the needs of the American medical student, in which he advocated as thorough a course in these subjects as is given in the other specialties, as, for instance, ophthalmology.

## SECTION IN PATHOLOGY AND PHYSIOLOGY.

CHAIRMAN, W. B. CANNON, BOSTON; SECRETARY, M. J. ROSENAU, WASHINGTON, D. C.

Chairman's Address, By WALTER B. CANNON.  
 A Critic of Some of the More Recent Work and Ideas on Nutrition, By L. BREISACHER.

CHAIRMAN, E. A. BOGUE, NEW YORK; SECRETARY, EUGENE S. TALBOT, CHICAGO.

- Chairman's Address, By E. A. BOGUE.  
 Dental Education, By M. L. RHEIN.  
 Pathology as Taught in Dental Schools, By L. G. NOEL.  
 State Reciprocity in Dental Practice Licensing, By ADELBERT H. PECK.  
 Some Practical Considerations Concerning Inflammation, By JAMES E. POWER.  
 Interstitial Gingivitis, By EDWARD C. BRIGGS.  
 Prophylaxis of the Mouth, By M. H. FLETCHER.  
 Aetiology of Face, Nose, Jaw, and Tooth Deformities, By EUGENE S. TALBOT.  
 Bone Pathology of Tooth Movement, By EUGENE S. TALBOT.  
 The Influence on the Nose by Widening the Palatal Arch, By LEE WALLACE DEAN.  
 The Relation between Deviation of the Nasal Septum and Dental and Jaw Deformities from the Rhinologist's Standpoint, By NELSON M. BLACK.  
 Diagnostic Value of Microscopical Examinations during Operations on Pathological Tissue, By VIDA A. LATHAM.  
 The Surgery of Harelip and Cleft Palate, By GEORGE V. I. BROWN.  
 Tumors Involving the Alveolar Process, By STEWART L. MCCURDY.  
 Some of the Diseases of the Salivary Glands and Their Ducts, By THOMAS L. GILMER.  
 Treatment of Mandibular Fractures, By ROBERT T. OLIVER.  
 Peripheral Causes of Facial Pains, Including Tic Douloureux, By MORRIS I. SCHAMBERG.  
 Nitrous Oxide and Oxygen Anesthesia in Dental and General Surgery, By FRED K. REAM.

## SECTION IN CUTANEOUS MEDICINE AND SURGERY.

- CHAIRMAN, M. B. HARTZELL, PHILADELPHIA; SECRETARY, M. L. HEIDINGSFELD, CINCINNATI.  
 Chairman's Address: The Nature and Causes of Eczema, By M. B. HARTZELL.  
 Nutritive and Neurotic Disturbances of the Hair, By L. D. BULKLEY and H. H. JANEWAY.  
 A Deceptive Case of Leprosy, By CHARLES J. WHITE and O. RICHARDSON.  
 X Ray Uses, Dangers, and Abuses, By W. S. GOTTHEIL.  
 The Treatment of Epithelioma by the Röntgen Rays, By G. E. PFAHLER.  
 Increasing Tendency to Recognize a Systemic Eczema and Systemic Treatment of Skin Disease, The Old and New in Cutaneous Therapy, By LUDWIG WEISS.  
 Pompholyx, a Study of Some Cases Personally Observed, By J. M. WINTERHILL.  
 Pompholyx Eruptions and Its Status among the Blemishes of the Skin, By W. F. CROFTON.  
 The Pathology of Pompholyx Eruptions, By O. C. SHURTLE.  
 A Case of Acute Ecthyma, An Acute Agent, a Chronic Lesion, By L. E. VALENTINE.

## Some Unusual Forms of Epithelioma of the Skin,

- By J. A. FORDYCE.  
 A Further Contribution to the Histopathology of Epidermolysis Bullosa, By M. F. ENGMAN and M. H. HOOK.  
 Paraffin Prosthesis. A Further Contribution on its Histopathology, By M. L. HEIDINGSFELD.  
 Multiple Hemorrhagic Sarcoma (Kaposi), By DAVID LIEBERTHAL.  
 Exhibition of Clinical Cases, By JOSEPH ZEISLER.  
 The Pigmentations of the Mucous Membrane of the Mouth, By H. G. ANTHONY.  
 Erythema Figurata Perstans, By GROVER W. WENDE.  
 Cheilitis Exfoliativa, By L. M. RAVITCH.  
 Mercurial Treatment for Late Manifestations of Syphilis, By HERMAN G. KLOPZ.  
 The Influence of the Discovery of the Pale Spirochæta on the Treatment of Syphilis, By W. F. BREAKER.  
 The Relation of the Character of the Syphilitic Initial Lesion to the Secondary Constitutional Process, By A. RAVOGLI.

## SECTION IN PHARMACOLOGY AND THERAPEUTICS.

CHAIRMAN, M. H. FUSSELL, PHILADELPHIA; SECRETARY, C. S. N. HALLBERG, CHICAGO.

- Chairman's Address: Simplicity in Prescribing, By M. H. FUSSELL.  
 Address of Chairman of Delegation from American Pharmaceutical Association, By JOSEPH P. REMINGTON.  
 Report of Secretary, By C. S. N. HALLBERG.  
 Trend of Pharmacology and Therapeutics in Relation to Chemical Research, By W. J. K. KLINE.  
 Osteopathic versus Drug Treatment, By M. CLAYTON THRUSH.  
 Work Cure, By ADDISON THAYER.  
 Physiological Assay of Some Commonly Used Drugs, By CHARLES W. EDMUNDS.  
 Sodium Cacodylate: Its Therapeutic Uses, By FRANK BILLINGS.  
 Arsenic in the Treatment of Diseases of the Skin, By MILTON B. HARTZELL.  
 The Specific Chemical Therapy of Trypanosomiasis and Spirillosis, By BENJAMIN T. TERRY.  
 Organotherapy, By REID HUNT.  
 General and Topical Applications in Advanced Laryngeal Tuberculosis, By S. SOLIS-COHEN.  
 Pneumotherapy in Pulmonary Tuberculosis, By S. SOLIS-COHEN.  
 The Use of Digitalis in Pneumonia, By THOMAS F. REILLY.  
 The Effects of Quebracho on the Respiration, By H. C. WOOD, JR.  
 Tincture Strophanthus and Strophanthin, with Especial Reference to Dosage, By R. A. HATCHER.

## Coincident Meetings.

### AMERICAN MEDICAL EDITORS' ASSOCIATION.

The thirty-ninth annual meeting of the American Medical Editors' Association was held in the Auditorium Hotel, Chicago, on Saturday, May 30th, and Monday, June 1st. The president, Dr. Charles F. Taylor, of Philadelphia, editor of the *Medical World*, in the chair. An interesting programme was carried out.

The following officers were elected for the coming year: President, Dr. T. D. Crothers, of Hartford, Conn., editor of the *Quarterly Journal of Inebriety*; first vice-president, Dr. W. A. Young, of Toronto, Canada, editor of the *Canadian Journal of Medicine and Surgery*; second vice-president, Dr. E. W. Taylor, of Boston, of the *Boston Medical and Surgical Journal*; secretary and treasurer, Dr. Joseph MacDonald, Jr., of New York, of the *American Journal of Surgery*; members of the executive committee, Dr. J. J. Taylor, of Philadelphia, editor of the *Medical Council*; Dr. W. C. Abbott, of Chicago, editor of the *Journal of Clinical Medicine*, and Dr. W. A. Jones, of Minneapolis, editor of the *Journal of the Minneapolis Medical Society*.

The banquet, which was held on the evening of Monday, June 1st, was well attended. Toasts were responded to by Surgeon General Wyman, of the United States Public Health and Marine Hospital Service; Colonel W. C. Gorgas, of the Isthmian Canal Commission; Dr. Charles A. L. Reed, of Cincinnati; Dr. W. A. Young, of Toronto; Dr. Henry O. Marcy, of Boston, and Dr. Wallace, of Chattanooga.

#### THE ASSOCIATION OF AMERICAN TEACHERS OF THE DISEASES OF CHILDREN.

The association held its annual meeting in the Great Northern Hotel, Chicago, Ill., on Monday, June 1st, at 2 p. m.

The following programme was presented:

Address of welcome, delivered by Arthur D. Bevan, of Chicago, chairman Council on Education of the American Medical Association.

Address of the president, by Dr. Samuel W. Kelley, of Cleveland, Ohio.

The Teaching of Pædiatrics as Seen by an Inspector of Medical Colleges, by Dr. Frederick C. Zapffe, of Chicago, Ill.

The Teaching of Pædiatrics in the European Schools, by Dr. H. M. McClanahan, of Omaha.

The Teaching of Pædiatrics in the Medicochirurgical College of Philadelphia, by Dr. W. C. Hollopeter, of Philadelphia.

Case Teaching in Pædiatrics, by Dr. William W. Butterworth, of New Orleans, La.

The Doctrine of Difficult Dentition, by Dr. Theodore J. Elterich, of Pittsburgh, Pa.

Anatomical Peculiarities of Infants and Children, by Richard B. Gilbert, of Louisville, Ky.

The discussion was opened by Dr. Philip F. Barbour, of Louisville, Ky.

What Conditions Demand Total Weaning and What Demand Partial Weaning of Infants during the First Two Weeks of Life? by Dr. Charles Douglas, of Detroit, Mich.

Some Points on Infants' Clothing, by Dr. Alfred C. Cotton, of Chicago.

The Urinary Infections in Children, by Dr. John Zahorsky, of St. Louis, Mo.

The discussion was opened by Dr. Isaac A. Abt, of Chicago.

Chorea in Its Relation to Tonsillitis, Rheumatism and Endocarditis, by Dr. William J. Butler, of Chicago.

Some Phases of the School Child, by Dr. J. W. Van Derslice, of Oak Park, Ill.

The discussion was opened by Dr. A. C. Cotton, of Chicago.

Uncinariasis in the Southern States, by Dr. J. Ross Snyder, of Birmingham, Ala.

The discussion was opened by H. M. Folkes, of Biloxi, Miss.

Treatment of Pneumonia in Children by the Outdoor Air Method, by Dr. Frederic W. Loughran, of New York.

The following officers were elected for the coming year: President, Dr. Charles Douglas, of Detroit; Secretary, Dr. Samuel W. Kelley, of Cleveland; Treasurer, Dr. George H. Cattermole, of Boulder, Col. Executive Committee, Dr. W. C. Hollopeter, of Philadelphia; Dr. H. M. McClanahan, of Omaha; and Dr. R. B. Gilbert, of Louisville.

#### THE AMERICAN ACADEMY OF MEDICINE.

The thirty-third annual meeting of the American Academy of Medicine was held in the Lexington Hotel, Chicago, on Saturday, May 30th, and Monday, June 1st. The president, Dr. Thomas D. Davis, of Pittsburgh, in the chair. The following programme was carried out:

I. Report of the Committee on the Best Means for the Medical Profession to Take Part in the Education of the General Public in Medical Matters through Publications, etc., by Dr. Edward Jackson, of Denver, Chairman.

II. Report of the Committee to Investigate the Teaching of Hygiene in the Public Schools; and

III. Report of the Delegate to the Second International Congress on School Hygiene, London, 1907, by Dr. Helen C. Putnam, of Providence, R. I.

IV. Report of the Committee on Conference with Educational Institutions on Medical Education, by Dr. Charles McIntire, of Easton, Pa., Chairman.

V. Report of a Special Committee to Formulate Conclusions from the Conference at Pittsburgh, January 2, 3, 1908, by Dr. John L. Heffron, of Syracuse, N. Y., Chairman.

VI. Report of the Delegate to the Annual Conference of the Council on Medical Education of the American Medical Association, Chicago, April 13, 1908, by Dr. Charles S. Sheldon, of Madison, Wis.

VII. Some Considerations of the Necessity for a Rational Curriculum for the Doctorate, by Dr. Henry Beates, Jr., of Philadelphia.

VIII. Annual Address. The Doctor and School Advice. This address was delivered by the president of the Academy, Dr. Thomas D. Davis, of Pittsburgh, Pa.

IX. Report of the Committee to Collect Data as to the Amount of Damage Done by Alcohol in Moderate Drinkers, by Dr. Woods Hutchinson, of New York, Chairman.

X. Report of the Committee to Prepare a Draft of an Act to Create a State Board of Medical Examiners, by Dr. Charles McIntire, of Easton, Pa., Chairman.

"SYMPOSIUM" ON THE PLACE OF WOMEN IN THE MODERN BUSINESS WORLD AS AFFECTING HOME LIFE, THE MARITAL RELATION, HEALTH, MORALITY, AND THE FUTURE OF THE RACE.

1. As Affecting the Home Life and the Marital Relation, by Dr. A. Stewart Lobinger, of Los Angeles.

2. As Affecting Health, by Dr. L. Duncan Bulkley, of New York.

3. As Affecting Health and Morals, by Dr. Norman Bridge, of Los Angeles.

4. As Affecting the Future of the Race, by Dr. Otto Juettner, of Cincinnati, Ohio.

5. As Affecting the Future Welfare of the Race, by Dr. Edward B. Heckel, of Pittsburgh.

6. Female Labor as a Factor in Social Life, by Dr. A. L. Benedict, of Buffalo.

The following officers were elected: President, Dr. Helen C. Putnam, of Providence. Vice presidents, Dr. Charles S. Sheldon, of Madison, Wis.; Dr. Mettler; Dr. J. K. Weaver, of Norristown, Pa.; Dr. Norman Bridge, of Los Angeles. Secretary and treasurer, Dr. Charles McIntire, of Easton, Pa. Assistant secretary, Dr. Alex. R. Craig, of Philadelphia.

## News Items.

**Change of Address.**—Dr. D. J. Milton Miller, to 1700 Pacific Avenue, Atlantic City.

**Women Physicians of Colorado Form an Association.**—The Woman's Colorado State Medical Association was recently incorporated, and every regular woman physician in the State will be asked to become a member.

**Buffalo Academy of Medicine.**—The regular meeting of the Section in Obstetrics and Gynecology was held on the evening of May 28th. The programme included a paper on The Conservation of Nervous Energy in the Parturient, by Dr. Peter W. Van Peyma, and a paper on The Treatment of Threatening and Inevitable Abortion, by Dr. William G. Taylor.

**St. John's Guild Opens Seaside Hospital.**—St. John's Guild opened the Seaside Hospital at New Dorp, Staten Island, on June 1st, when two parties of babies and little children, with their mothers, were sent to the hospital on the Staten Island ferryboats. The guild will continue to convey patients to the hospital by boat twice daily, except Sundays, until the Floating Hospital begins its trips, which will be about July 6th.

**Scientific Society Meetings in Philadelphia for the Week Ending June 13, 1908.**—Monday, June 8th, Wills Hospital Ophthalmic Society. Tuesday, June 9th, Philadelphia Paediatric Society; Botanical Section, Academy of Natural Sciences. Wednesday, June 10th, Philadelphia County Medical Society. Thursday, June 11th, Pathological Society; Section Meeting, Franklin Institute. Friday, June 12th, Northern Medical Association; West Branch, Philadelphia County Medical Society.

**The Japanese Red Cross Society.**—The sixteenth anniversary of the founding of this society was held in Hibiy Park, Tokio, on June 1st. The society now has a membership of 1,414,225, including 504 Americans, 590 Koreans, and 6,440 Chinese. The value of its property exceeds \$7,000,000. Connected with its medical staff are 212 doctors, 143 pharmacists, and 3,369 nurses, 668 male and 2,701 female. Since the Russo-Japanese war the society has put into commission two large hospital ships, in addition to the two already in use.

**Charitable Bequests.**—By the will of Frederick Roemle the German Hospital, Brooklyn, receives \$500, and the German Home for the Aged receives \$250.

By the will of Mary Ann Astor Woodcock the Methodist Episcopal Hospital, Brooklyn, receives \$5,000.

By the will of Annie Cohen the Jewish Hospital, Brooklyn, receives \$1,000.

By the will of James Henry Smith St. Luke's Hospital, New York, receives \$100,000, and the New York Orthopedic Hospital and Dispensary receives \$100,000.

**American Gynecological Society.**—The twenty-third annual meeting of this society was held in Philadelphia on May 25th, 26th, and 27th. Dr. August Martin, of Berlin, and Dr. F. Pfannenstiel, of Kiel, were guests of the society. The following officers were elected to serve for the year 1909: President, Dr. J. Riddle Goffe, of New York; first vice president, Dr. Howard Kelly, of Baltimore; second vice president, Dr. M. McLean, of New York; secretary, Dr. Le Roy Broun, of New York; treasurer, Dr. J. Wesley Boyce, of Washington, D. C. The next meeting will be held in New York in May, 1909.

**Cases of Tuberculosis Must Be Reported in New York.**—A bill has been enacted in the New York legislature providing that physicians attending cases of tuberculosis shall make a report of such cases to the local health authorities, and shall put into effect such precautions as may be prescribed by the local authorities to prevent the spread of the disease. The bill provides that a fee of \$1 shall be paid out of the funds of the local government for each physician who carries out the precautions prescribed by the authorities. The measure resembles in many particulars a law which has been in force for the past few years in Maryland.

**Appointments and Promotions at the Rockefeller Institute for Medical Research.**—The following appointments have been made to the staff of this institution: Dr. P. A. Lewis, assistant in pathology; Dr. A. J. Kessel, assistant in bacteriology; Dr. A. R. Dodge, fellow in physiology; Dr. A. O. Shaker, fellow in physiology and pharmacology.

Promotions have been made as follows: Dr. John Auer, associate in physiology and pharmacology; Dr. Don R. Joseph, assistant in physiology and pharmacology; Dr. Alexis Carrel, associate in surgery; Dr. J. W. Jobling, associate in pathology; Dr. Benjamin T. Terry, assistant in protozoology; Dr. Donald D. Van Slyke, assistant in biological chemistry; Dr. Walter A. Jacobs, assistant in biological chemistry; Dr. Bertha I. Barker, fellow in pathology; Dr. R. V. Lamar, fellow in pathology.

**The Mortality of Chicago.**—According to the report of the Department of Health, during the week ending May 23, 1908, there were reported to the department 495 deaths from all causes, as compared with 635 for the preceding week, and 641 for the corresponding period in 1907. The annual death rate in 1,000 of population was 11.92. The principal causes of death were: Apoplexy, 8; Bright's disease, 43; bronchitis, 13; consumption, 54; cancer, 26; convulsions, 5; diphtheria, 6; heart diseases, 53; influenza, 2; intestinal diseases, acute, 23; measles, 11; nervous diseases, 16; pneumonia, 57; scarlet fever, 6; suicide, 5; typhoid fever, 2; violence (other than suicide), 22; whooping cough, 2; all other causes, 141.

**Meetings of State Medical Societies for the Month of June:**

Michigan State Medical Society, annual meeting at Manistee, Mich., on June 24th and 25th.

Maine Medical Association, annual meeting at Bangor, Me., on June 10th and 11th.

Massachusetts Medical Society, annual meeting at Boston on June 10th and 11th.

Medical Society of New Jersey, annual meeting at Cape May, N. J., on June 18th, 19th, and 20th.

State Medical Society of Wisconsin, annual meeting at Milwaukee on June 24th, 25th, and 26th.

**Philadelphia Academy of Surgery.**—A stated meeting of this academy was held on the evening of June 1st. Dr. James K. Young reported a case of exploratory arthrectomy. Dr. John W. Price reported four cases of Ludwig's angina. A paper on the End Results of Fractures of the Femur Treated Conservatively was presented by Dr. A. P. C. Ashhurst and Dr. William A. Newell. Dr. G. G. Davis read two papers, one describing an operation for the cure of enuresis, and the other giving the details of a method of anastomosing the divided vas deferens. Dr. W. Estell Lee read a paper entitled The Use of Ethyl Chloride as a General Anæsthetic at the Pennsylvania Hospital, with a Report of Five Thousand Cases.

**A Hospital for the Rockefeller Institute for Medical Research.**—The board of directors of this institution announce the receipt of a gift of \$500,000 from Mr. John D. Rockefeller, to be used for the erection and equipment of a hospital in connection with the institute. The hospital will be small compared with many others in the city, as its purpose is not so much to provide accommodations for the many as to furnish the means of studying the nature and treatment of individual cases, and thus develop new and more exact methods which may be applied elsewhere upon a larger scale. The hospital will contain certain elaborate provisions for the fresh air treatment of patients, and special departments of hydrotherapy, and electrotherapeutics. It will contain private rooms, as well as public wards, and a special diet kitchen.

**Personal.**—Dr. Carl Beck, of New York, has been decorated with the Order of the North Star by the King of Sweden.

Dr. H. Sheridan Baketel, of New York, has been awarded the honorary degree of Master in Arts by Hobart College.

Dr. W. C. Jones, of Mobile, Ala., is registered at the Philadelphia Polyclinic and College for Graduates in Medicine.

Dr. Elmer D. Barnes, of Philadelphia, is appointed vice president of Temple University.

Dr. Robert Koch, the German bacteriologist, whom the Honorable committee on his trip around the world named the famous Kaper Professor, on the island of Malindi, where he went to investigate the cause of malarial fever.

Dr. G. A. De Saenz, of New York, has been appointed instructor in bacteriology at the New York Postgraduate Medical School and Hospital. Dr. Saenz will be attached to the class of Dr. Ramon Gonzalez, and will deliver a course of lectures in general bacteriology during the present season.

**Vital Statistics of New York.**—During the week ending May 23, 1908, there were reported to the Department of Health 1,463 deaths from all causes, as compared with 1,405 for the preceding week, and 1,447 for the corresponding period in 1907. Of the total number of deaths 740 were in Manhattan, 130 in the Bronx, 507 in Brooklyn, 57 in Queens, and 29 in Richmond. The annual death rate in 1,000 of population was 16.84 in Manhattan, 20.70 in the Bronx, 17.72 in Brooklyn, 12.78 in Queens, 19.73 in Richmond, and in the whole city, 17.26. The total infant mortality was 360; under one year of age, 268; between one and two years of age, 98. There were 156 still births. Six hundred and sixty-two marriages and 2,239 births were recorded during the week.

#### Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Department of Health for the following statement of new cases and deaths reported for the two weeks ending May 30, 1908:

	—May 23—		—May 30—	
	Cases.	Deaths.	Cases.	Deaths.
Tuberculosis pulmonaryis	420	201	341	105
Diphtheria	307	37	344	—
Measles	1,535	34	1,230	33
Scarlet fever	1,053	49	948	49
Smallpox	—	—	—	—
Varicella	144	—	262	—
Typhoid fever	32	1	12	12
Whooping cough	24	1	—	—
Cerebrospinal meningitis	12	9	—	8
To als	3,037	348	2,824	97

**Examination for Technical Assistant in Pharmacology.**—The United States Civil Service Commission announces an examination on July 1, 1908, to secure eligibles from which to make certification to fill a vacancy in the position of technical assistant, Division of Pharmacology, Hygienic Laboratory, Public Health and Marine Hospital Service, at \$150 a month, and vacancies requiring similar qualifications as they may occur in any branch of the service. Applicants must have received either the degree of M. D. or Ph. D. from institutions of high standing, and must submit evidence of ability to do research work. They must also be able to read French and German. Applicants should apply to the United States Civil Service Commission, Washington, D. C., for application Form 304 and special form, and for any further information regarding the examination.

**The Health of Pittsburgh.**—During the week ending May 16, 1908, the following cases of transmissible diseases were reported to the Bureau of Health: Chickenpox, 1 case, 0 deaths; typhoid fever, 26 cases, 2 deaths; scarlet fever, 32 cases, 1 death; diphtheria, 6 cases, 0 deaths; measles, 201 cases, 7 deaths; pulmonary tuberculosis, 21 cases, 13 deaths. The total deaths for the week numbered 143, in an estimated population of 403,330, corresponding to an annual death rate of 18.43 in 1,000 of population. During the week ending May 23, 1908, the following cases of transmissible diseases were reported: Chickenpox, 5 cases, 0 deaths; typhoid fever, 24 cases, 3 deaths; scarlet fever, 18 cases, 1 death; diphtheria, 5 cases, 0 deaths; measles, 248 cases, 5 deaths; whooping cough, 10 cases, 2 deaths; pulmonary tuberculosis, 34 cases, 8 deaths. The total deaths for the week numbered 143, corresponding to an annual death rate of 18.43 in 1,000 of population.

**Philadelphia Bureau of Health Statistics.**—During the month of April, 1908, in the Division of Medical Inspection, 3,420 inspections were made, exclusive of schools; 520 fumigations were ordered; 28 cases were referred for special diagnosis; 6,335 visits were made to schools; 998 children were excluded from school; 215 cultures were taken; 114 injections of antitoxine were given; and 190 persons were vaccinated. In the Division of Vital Statistics, 2,042 deaths, 2,880 births, and 1,180 marriages were reported. In the Division of Milk Inspection 9,780 inspections were made of 230,420 quarts of milk, of which 885 quarts were condemned. Twelve specimens were examined chemically and 1,105 microscopically. In the Division of Meat and Cattle Inspection 3,488 inspections were made; 94 were found unsanitary; 102 pieces of dressed meats were condemned, and 1,028 post mortem examinations were made, of which 72 were condemned. In the Division of Disinfection 4 fumigations were done for smallpox, 335 for scarlet fever, 309 for diphtheria, 85 for typhoid fever, 218 for tuberculosis, 41 for cerebrospinal diseases, and 4 school were fumigated. In the Bacteriological Laboratory 950 cultures were examined for the presence of bacillus diphtheriae, 376

specimens of blood were examined for the serum diagnosis of typhoid fever; 1,105 specimens of milk were examined; 174 specimens of sputum were examined; 8 disinfection tests were made; and 3,771,100 units of antitoxine were distributed. In the Chemical Laboratory 134 analyses were made.

**Maine Medical Association.**—The fifty-sixth annual meeting of this society will be held in the City Building, Bangor, on Wednesday and Thursday, June 10th and 11th. Sessions will be held at 9 a. m. and at 2 p. m. on both days. A splendid programme has been arranged, which includes eighteen papers on practical subjects by prominent members of the medical profession. The annual oration will be delivered on Thursday evening at 7:30 o'clock by Dr. Hobart Amory Hare, of Philadelphia. His subject will be Hold Fast to that which is Good in Diagnosis and Therapeutics. After the oration the annual dinner will be served at the Bangor House. The officers of the society are: President, Dr. B. B. Foster, of Portland; first vice president, Dr. Alfred D. Sawyer, of Fort Fairfield; second vice president, Dr. O. C. S. Davis, of Augusta; secretary, Dr. Walter E. Tobie, of Portland; treasurer, Dr. Arthur S. Gilson, of Portland.

**The Massachusetts Medical Society.**—The one hundred and twenty-seventh annual meeting of this society will be held in the Mechanics Building, Boston, on Tuesday and Wednesday, June 9th and 10th. Tuesday afternoon will be devoted to the reading of scientific papers, and on Tuesday evening the Shattuck lecture will be delivered in Paul Revere Hall. On Wednesday morning the annual oration will be given, and at 1 p. m. the annual dinner will be served. There will be pathological and commercial exhibits on both days, and the Society for the Relief and Control of Tuberculosis will have a large exhibition of appliances used in the outdoor treatment of tuberculosis. The District Committee for the Prevention and Control of Tuberculosis will meet in Paul Revere Hall at 3 p. m. on Tuesday. Additional information regarding the meeting may be obtained by addressing Dr. George S. C. Badger, chairman of the committee of arrangements, 48 Hereford Street, Boston.

**The Northwestern Medical Society of Philadelphia.**—The members of this society held a clinical conference on the evening of June 1st. Dr. S. W. Newmayer read a paper entitled Defective Vision and the Mentally Subnormal Child. Dr. Wendell Reber opened the discussion. Dr. J. O. Arnold reported a case of recurrent pseudopyosis. Dr. Nathan McManus reported two interesting cases of typhoid fever. Dr. William McKeage reported a case of tonsillitis followed by sudden death. Dr. E. E. W. Given read a paper entitled A Plea for a More Liberal Diet in Typhoid Fever. Dr. C. S. Barnes presented a preliminary report of a case of hydrophobia. Dr. H. Hudson read a paper on An Unusual Series of Hip Joint Diseases in One Family. Dr. Carl Lee Felt exhibited some interesting nose and throat cases. Dr. Luther C. Peter exhibited patients showing the result of Calmette's ophthalmoreaction, and patients with interesting eye symptoms in multiple sclerosis and hysteria. Dr. J. Thompson Schell exhibited a patient with a dislocated tuberculous shoulder, and reported a case of Cesarean section with a double indication.

#### Society Meetings for the Coming Week:

**MONDAY, June 8th.**—New York Academy of Medicine (Section in Neurology and Psychiatry); Society of Medical Jurisprudence, New York; New York Ophthalmological Society; Corning, N. Y., Medical Association; Waterbury, Conn., Medical Association.

**TUESDAY, June 9th.**—New York Academy of Medicine (Section in Public Health); Medical Society of the County of Schenectady, N. Y.; Practitioners' Club of Jersey City, N. J.; Medical Society of the County of Rensselaer, N. Y.; Buffalo Academy of Medicine (Section in Medicine).

**WEDNESDAY, June 10th.**—New York Pathological Society; Medical Society of the Borough of the Bronx; Brooklyn Medical and Pharmaceutical Association; Richmond County, N. Y., Medical Society.

**THURSDAY, June 11th.**—New York Academy of Medicine (Section in Pediatrics); Brooklyn Pathological Society (annual); Blackwell Medical Society of Rochester, N. Y.

**FRIDAY, June 12th.**—New York Academy of Medicine (Section in Otolaryngology); Eastern Medical Society of the City of New York.

By AUGUSTUS A. ESHNER.

#### 1. Incomplete Myxœdema (Hypothyroidæa).

—Elliott says that the diagnosis of a well marked, fully developed case of myxœdema is readily made owing to the striking character of the symptoms. The appearance of the patient is so peculiar that the disease can be recognized at a glance. It is quite otherwise when the disease is encountered in its early stages or in atypical form. Slight evidences of the condition may readily be overlooked. The profound nutritional changes, which are so striking in cases of more complete development, are absent, or present only in modified degree. Most of the cases of hypothyroidæa are encountered in women at, or approaching, the climacteric, and the symptoms are usually ascribed to the menopause. The predominance of myxœdematous states in the female is well attested by statistics, the ratio being 7 to 1. This undoubtedly is due in great measure to the repeated hyperfunction and irritation of the thyroid resulting from the vicissitudes of woman's reproductive life. A history of hyperthyroidæa in earlier life is not without value from the ætiological standpoint. Hun and Prudden point out that the great majority of women who suffer from myxœdema have borne children, and only a small proportion are unmarried. This may point to a secondary atrophy following puerperal hyperthyroidæa. In no other way can the great disproportion in frequency between the two sexes be explained than by interpreting many of the cases in the female as due to secondary atrophy induced by the thyroid hyperfunction of pregnancy and lactation. A few cases both of the fully developed and modified forms of myxœdema have been reported in which the apparent starting point was an acute infection. It is very doubtful whether such cases are true instances of postinfective myxœdema, although such a possibility cannot be denied. It is more probable that the disease had previously existed in a latent form and

that the acute infective toxæmia provoked an exacerbation. Hypothyroidæa and myxœdema may develop following Graves's disease, sometimes years afterward. Glandular hyperæmia and hyperfunction have here passed over into a state of secondary atrophy with hypofunction.

2. Spinal Infantile Paralysis.—Collins and Romeiser remark that the epidemic occurrence of anterior poliomyelitis is firmly established. The dependence of the disease on infection may therefore be legitimately assumed. The epidemic that prevailed in New York in the summer and autumn of 1907 afforded the authors unusual opportunity to study the disease, and present in tabulated form the analysis of 327 cases from that epidemic and 173 cases observed previous to that time. The figures relative to the age are very striking; 95 per cent. of the patients were under 5 years, 70 per cent. were between 1 and 3 years, and 33 per cent. during the second year. The vulnerable age is, therefore, from 1 to 3 years. In regard to paralysis that accompanies lesion of the epidemic cases of 1907, it was most frequently of the lumbar enlargement, next often of the cervical and dorsal cord, but not infrequently bulbar. There were all possible degrees and combinations. Two isolated facial "nuclear" paralyses were observed during the height of the epidemic. Paralysis of the diaphragm was observed in one instance only, accompanying forced inspiratory efforts of the intercostal muscles. No definite or constant relation was observed between the degree or duration of fever and the severity or extent of the paralysis, but it was distinctly made out that in all quadriplegias there had been a distinct febrile stage, whereas it was chiefly in the monoplegias that a history of "no fever" or "slight" was obtained. Trauma, such as a fall, or physical exhaustion is sometimes, though not often, a definite antecedent. One child fell out of the window. Another, two years old, walked the unusual distance of three miles just previous to the onset of the fever, and in several instances there was a history of profound fatigue. In general, physical shock or overexertion plays a minor rôle in the ætiology and is at most a predisposing factor. Occasionally a fall while walking is the first indication of a preexistent paralysis. A striking feature is the fact that by far the greater number of children were in the best of health at the time of onset, many of them without previous illness of any moment. In regard to the onset it may be said that the disease develops with and without warning, but usually with vomiting and fever. In many instances the child had gone to sleep apparently well. Sometimes the paralysis was evident the next morning, but usually from two to four days afterward. In few cases only was it noted that the fever continued after the appearance of the paralysis. As the somnolence, pain, and hyperæsthesia (especially marked on active or passive movements) are accompanied in many cases by immobility, it is often days and sometimes a week before the paralysis is noted. The ~~onset~~ <sup>onset</sup> time and order of onset and even initial distribution of the paralysis is not often determinable with the exactness which the statistician requires for reliable conclusions. Both the ascending and the descending Landry types of paralysis were observed in a few instances.

3. **Spondylitis Deformans.**—Diller and Wright say that the ætiology of spondylitis deformans has not yet been fully determined. The disease is about three times as common in men as in women, and it occurs most frequently between the ages of twenty-five and forty-five. Habits involving exposure to changes in temperature, hard work, and poor hygiene generally are important predisposing causes. Heredity and trauma appear to play a rôle in some cases. Finally it seems probable that some toxic or infectious agent acts as an important factor in many cases. As regards the symptoms, these are referable, as would be expected, to the spine, and to other joints involved in the same osteoarthritic process, to the spinal nerves. The onset is gradual and insidious, very rarely acute, though this may occur. The first symptoms noted are pain and stiffness in the spine, in the earlier stages, most noticeable after a period of rest, as when the individual is getting out of bed or out of a chair. At times this may be felt only on nodding the head or on stooping. The pain may be in the spine itself or referred to the nerve distribution, accompanied also by anæsthesias, paræsthesias, hyperæsthesias, and trophic disturbances. Pains early in the disease are characteristic; later as movement in the spine is limited or lost, and there has been a contraction and ossification of the exostosis, pressure on the nerve roots is relieved and pain may practically disappear. With the gradual extension of the process, movement in the spine becomes more and more limited and finally *nil*, so that the sufferer is unable to move his spine at all or even nod his head, a condition well meriting the oft applied term "poker back." Depending on the seat of onset this stiffness may be limited to the cervical, thoracic, or lumbar region, and progress no further. Beside the spine, any other joints may be involved, more especially those of the shoulder and pelvic girdle. The ribs by reason of ossification of the costovertebral articulations may lose their normal range of motion, which is noticed early by the patient on attempting a deep inspiration. Of the treatment the authors observe that once the diagnosis is made they believe that the patient should be put into the hands of a competent orthopaedic surgeon. The patient needs most painstaking care, both as to his general and local condition. The general health should be improved to the highest possible degree and the faulty action of any organ in the body corrected. Any possible source of infection should be removed, and to this end a careful examination should be made of the nasopharynx, the gastrointestinal, and genitourinary tracts, and the skin. On account of the danger of upsetting the stomach, there is little place for drugs. Tonics, fresh air, sunlight, good nutritious food, rest, and restfulness should comprise the armamentarium. As regards the local treatment, in the early stages some method of fixation for the spine should be used, either of plaster or steel. This prevents the irritation of the diseased vertebræ and relieves pain and stiffness. Later, as the process has subsided, passive motion and massage may be used with benefit. The spine in old cases should not be fixed, for here our object should be to ward off by massage and movements the tendency to complete ankylosis. The authors conclude that an infection of some kind, apparent or hidden,

plays an important rôle in the ætiology of this disease. Except for clinical purposes, we are not yet warranted in classifying this disease into two separate and distinct types. The probability is that spondylitis deformans is not a distinct entity, but a clinical term covering many perhaps ætiologically and pathologically distinct diseases in which spinal stiffness is the most prominent symptom. Proper treatment in early cases, as a rule, brings good results; in later cases it relieves distressing symptoms. There is need of clinical records covering the subsequent history of these cases, for further developments may throw new light on the ætiology and exact diagnosis. There is great need of additional evidence from the postmortem table.

#### MEDICAL RECORD.

May 30, 1908.

1. *Melæna Neonatorum*, with Report of a Case Cured by Transfusion, By SAMUEL W. LAMBERT.
2. The Distinctive Diagnosis of Meningococcus Cerebrospinal Meningitis from Other Types of Cerebrospinal Meningitis, By HENRY W. BERG.
3. A Plan for Reducing Infant Mortality in New York City, By WILBUR C. PHILLIPS.
4. The Correlation of Eyestrain and the Functional Neuroses, By HOMER E. SMITH.
5. Disturbances of Gastric Secretion; a Practical Study, By M. GROSS.
6. Drainage of Wounds, By R. W. KNOX.
7. Some Observations on the Ophthalmotuberculin Reaction, By THEODORE B. SACHS.

1. *Melæna Neonatorum.*—Lambert reports such a case. The baby was a girl, born of healthy parents. Subcutaneous bleeding extended down the neck over the muscles, across the median line to the other ear across the coronal suture over the frontal bone, and forward under the left ear to the angle of the jaw. The bleeding from the nose was continuous and quite profuse. A dark meconium stool gave a very positive reaction for blood, but the urine was of normal color. The baby was of waxen pallor. The diagnosis of melæna was made, and treatment instituted upon the theory of its being an intestinal infection. One dose of thirty minims of castor oil and two grain doses of calcium lactate every two hours was given during the night. The scalp hæmatoma increased in size and tenseness, and the paleness of the skin increased, but the temperature gradually fell from the maximum of the attack at 104.4° F. till it reached 97.4° F., the nasal bleeding became less constant, and the baby nursed regularly. Adrenalin was tried in the nose, but without effect. It was decided to attempt a direct transfusion of blood from the father of the infant by end to end anastomosis of the two bloodvessels after the manner devised by Dr. Carrel, of the Rockefeller Institute. This was done. The right popliteal vein of the baby was sutured to the left radial artery of the child's father, without anæsthetic to either patient, and enough blood was allowed to flow into the baby to change her skin from a pale transparent whiteness to a brilliant red color. No measure of the amount of blood was possible, but the evidences of a sufficient quantity were manifold. She began to cry lustily and to struggle against the bandages, which held her strapped to an ironing board. The wound in the leg up to this time had oozed a slight amount of pale, watery blood, which did not clot well. It began to bleed freely and the blood prompt-

ly clotted. The nosebleed stopped instantly. The pulse became full and strong and slowed down, and the respirations were deep and full. As soon as the wound was sutured and dressed, the baby was fed an ounce of milk, which she took ravenously and retained, and immediately went to sleep. Convalescence from the operation was uninterrupted except for a slight infection of the wound. There was no evidence of hæmolytic action at any time, and all the symptoms of melæna ceased at once. The hæmatoma was absorbed rapidly, except for a slight discoloration of the upper lid of the right eye. The stools became of normal character two days after the operation. The wound is healed, and the child appears to be a normal child of its age to-day.

**2. Distinctive Diagnosis of Meningococcus Cerebrospinal Meningitis from Other Types of Cerebrospinal Meningitis.**—Berg observes that in a general way the microscopic appearance of the fluid yields some indications as to the bacteriological character of the meningeal process. Thus a purulent turbid fluid speaks for meningococcus cerebrospinal meningitis; a comparatively limpid, clear fluid containing flocculi or fibrinous shreds or a slender white coagulated column, branching out at the top and base like a slender pillar supporting a capital in a test tube half filled with clear cerebrospinal fluid indicates tuberculous meningitis. The diagnosis resting upon such macroscopic appearances, however, rests upon but a slender reed, and to clinch it the bacteria should be found by staining or culture. In almost all cases of cerebrospinal meningitis, as distinguished from toxic pseudomeningitis, the normal tension of the fluid in the sub-arachnoid space is increased, and the fluid issues through the trocar under increased pressure; while this rule is not uniform, it is safe to state that increased pressure indicates an abnormal and not a sterile cerebrospinal fluid. For the purpose of bacteriological diagnosis of the disease during life, the meningococcus must be sought for in the cerebrospinal fluid obtained by lumbar puncture. It can be demonstrated by culture and microscopically. Cultures made from fluid obtained by lumbar puncture early in the disease will give positive results in a very large proportion of cases. Whether the agglutinating reaction will be found to be sufficiently reliable and exclusive to use the method for diagnostic purposes after the manner of the Widal reaction in typhoid fever, remains to be seen. The diplococcus can also be found in the nasal discharges of patients suffering from the disease, both microscopically and by culture. If lumbar puncture is done early in the disease, a cloudy fluid will be obtained, containing pus cells in which the organisms are found; later in the disease, with a clearer cerebrospinal fluid, the result may be negative. Diplococci are more apt to be found in fluid obtained during the acute stage or during an exacerbation. When the case is one of toxic pseudomeningitis, the fluid obtained by lumbar puncture is sterile and clear. This, then, is the one reliable and decisive factor in the distinctive diagnosis of these two conditions. When, however, a cerebrospinal meningitis of the meningococcus type is to be distinguished from a cerebrospinal meningitis of other bacteriological types mentioned, subjective and objective,

symptomatology is frequently not a decisive aid in the differential diagnosis. In cerebrospinal meningitis of the tuberculous type, there is generally a longer prodromal period; there is no leucocytosis unless suppurating processes are complicating the tuberculous meningitis; there are more frequently signs of chronic basilar meningitis, resulting in paralysis of the third, fourth, seventh, and bulbar nerves in tuberculous meningitis, while in meningococcus meningitis the opisthotonos is apt to be more marked and more frequent, and yet after all in these various types of meningitis the conclusive distinguishing factor will be the finding of the bacteriological organism which is the causative factor in the given case of meningitis.

**4. The Correlation of Eyestrain and the Functional Neuroses.**—Smith says that the ocular conditions which give rise to eyestrain may be refractive, accommodative, or muscular. The result is loss of neuricity. The effects are remote and reflex, and may be expended upon any organ, group of organs, the nervous system as a whole, or its separate divisions. It is the little refractive errors which give rise to the greatest trouble; poor vision and eyestrain are not concomitant conditions, but exactly the reverse. It is imperative to have the eyes of all children of school age examined under atropine; not only may health and comfort be conserved, but their whole future may rest upon this simple thing. Refractive errors of high degree should be corrected, not because of any reflex disturbances, but to save the eyes from disease and to give their possessor better vision. The investigation of all obscure nervous phenomena should begin with the eyes; often it will be necessary to go no further. Typical sick headache is pathognomonic of eyestrain; if it is not cured in 99 per cent. it is the fault of the refractionist.

#### BRITISH MEDICAL JOURNAL

May 16, 1908.

1. The Anatomy of the Pancreas in Relation to Its Diseases (Banks Lecture), By A. W. M. ROBSON.
2. Fracture of the Patella Treated by Mobilising the Lower Fragment, By J. L. THOMAS.
3. A Case of Ectopic Gestation with Unusually Early Symptoms, By E. A. SEARLE.
4. A Method of Obtaining Rapid Healing of Acute Abscesses, By J. PHILLIPS.
5. Tumor of the Orbit Removed without Enucleation and without Loss of Sight, By G. APTHOMAS.
6. Appendicitis Complicated by Hepatic Abscesses, By G. P. BLETHLEY.
7. The Influence of Pregnancy upon Certain Medical Diseases and on Certain Medical Diseases upon Pregnancy (Goulstonian Lectures, III), By H. FRENCH.

**1. Diseases of the Pancreas.**—Robson states that pathological changes in the pancreas may originate in any of its constituent parts. Inflammation starting in the ducts is at first of a catarrhal nature analogous to cholangitis, with which it is frequently associated. If the infective catarrhal condition is acute in character it may go on to diffuse suppurative catarrh or to a localized suppuration ending in abscess. If the infection is less virulent, it may not assume the more immediately dangerous suppurative form; but a chronic inflammation may extend to the parenchyma of the gland, leading to an increase of the connective tissue, eventually resulting in a condition resembling that seen in cirrhosis of

the liver. An increase of fibrous tissue may occur primarily around the bloodvessels as the result of changes in them or in their contents, and give rise to a cirrhotic condition. In some instances it is probable that, as a result of toxic substances circulating in the blood, the islands of Langerhans become first affected, as in amyloid disease of the gland. On the other hand, the acute infective parenchymatous inflammations known as acute hæmorrhagic, suppurative, or gangrenous pancreatitis, give rise to the most terrible and rapidly fatal diseases that the surgeon can be called on to treat. The various inflammatory conditions may be classified as follows: 1. Catarrhal inflammations. (a) Simple catarrh, acute and chronic. (b) Suppurative catarrh. (c) Pancreolithic catarrh. 2. Parenchymatous inflammations. *Acute.* (a) Hæmorrhagic pancreatitis. (1) Ultra-acute, in which the hæmorrhage precedes the inflammation, the bleeding being profuse and within and outside the gland. (2) Acute, in which inflammation precedes the hæmorrhage, which is less profuse and is distributed in patches throughout the gland. (b) Gangrenous pancreatitis. (c) Suppurative pancreatitis (diffuse suppuration). *Subacute.* Abscess of the pancreas (not diffuse suppuration). *Chronic.* (a) Interstitial pancreatitis. (1) Interlobular. (2) Interacinar. (b) Cirrhosis of the pancreas. Pancreatic calculi are rare and are apparently the result of catarrh of the ducts with stagnation of secretion, and instead of calculi being formed the ducts may be actually lined with calcareous material. The presence of lime salts renders pancreatic calculi opaque to the x rays, a valuable point in diagnosis. The ultimate effect of pancreatic lithiasis is toward complete destruction of the gland by a process of interstitial pancreatitis ending in fibrosis. Surgery offers a reasonable chance of cure if operation is done early. Cancer of the pancreas is much more common than was previously supposed; formerly secondary growths in the liver were thought to be primary. In most cases cancer of the pancreas is painless, especially in its early stages. When the body or tail of the gland is affected the only evidence of disease may be failure of health and loss of strength, together with signs of disturbed metabolism, as revealed by examinations of the fæces and urine; for obstruction of the ducts by a neoplasm brings about chronic inflammatory changes in the gland beyond the obstruction. When the head of the gland is affected the common bile duct becomes obstructed, and jaundice, rapidly becoming intense and absolute, manifests itself, producing characteristic signs of the disease—rapid loss of flesh and jaundice of painless onset, with distention of the gallbladder—conditions which may be simulated by chronic interstitial pancreatitis. In the latter case the pancreatic reaction in the urine will be of assistance in diagnosis. Cancer or sarcoma of the head of the gland is necessarily rapidly fatal, and incapable of marked relief. Even palliative operations of short circuiting the obstruction by cholecystenterostomy are peculiarly fatal in malignant cases.

4. **Treatment of Acute Abscesses.**—Phillips contends that in almost every case of acute abscess there need not be left any source of irritation to continue to act for a considerable time, and that, unless dead bone or some other irremovable irritant is pres-

ent, something not unlike primary union is obtained. Method. 1. Cleanse the skin as in operating on sterile tissues. 2. Make an incision long enough to permit of the pus being freely evacuated and the pyogenic membrane rubbed clean and smooth with gauze wrapped around the finger. 3. Having emptied the abscess cavity as completely as possible, pack it tightly with gauze (1 to 1,000 mercury bichloride gauze, dry) and apply a wool dressing and bandage as firmly as possible. 4. At the end of forty-eight hours remove the packing and dress the wound as if it were a simple incision; that is, do not pack or drain at all, but simply fix a gauze and wool dressing firmly in place with a bandage. This dressing will require changing only once in three or four days until the incision is soundly healed, and it will be found that the sides of the abscess cavity unite promptly and that there is no outpouring of pus from it. From the time when the packing is removed it is practically a simple incised wound that is being treated. The writer asserts for this method that it results in rapid healing; that the constitutional symptoms are gotten rid of almost at once; that as the dressing requires doing so seldom the doctor can do it himself and so avoid the risk of a secondary mixed infection; and, finally, it effects quite a marked economy in dressings.

## LANCET.

May 16, 1908.

1. The Connective Tissue in Carcinoma and in Certain Inflammatory States that Precede Its Onset (Hunterian Lectures, I). By V. BONNEY.

3. Juvenile Tabes Dorsalis: Notes of Five Cases. By S. STEPHENSON.
4. A New Method of Restoring the Continuity of the Bowel in Cases of Excision of a Growth Low Down in the Sigmoid Flexure. By J. P. L. MUMMEY.
5. The Diagnosis of Perforating and of Chronic Duodenal Ulcer. By SIR J. F. H. BROADBENT.
6. A Method of Administering Solids in Cases of Gastrostomy. By A. E. MAYLARD.
7. The Electrical Treatment of Atonic Conditions of the Digestive System. By R. MORTON.
8. Note on Two Cases of Chronic Dysentery Treated with Forster's Antidysenteric Vaccine. By E. A. R. NEWMAN.
9. Note on a Case of Functional Paraplegia with Associated Paralysis of the Bladder. By A. ROSE.

1. **Connective Tissue and Cancer.**—Bonney in the first of his Hunterian lectures on connective tissue and cancer makes a general survey of the connective tissue changes in primary carcinomata. *Lymphocytes* are a conspicuous feature of the cell proliferation surrounding an early carcinoma, being specially aggregated at the tips of the epithelial processes. Their origin is very difficult to decide, and they certainly take no part in the formation of the stroma of the growth. There is no increase in the lymphocytes in the blood until a late stage of the disease. *Plasma cells* are the most striking objects seen in the connective tissue around a cancer. They are rarely in contact with the epithelial cells. The writer thinks they originate from certain elongated small nuclei, found in resting connective tissue. It is probable that the plasma cells, together with the fixed connective tissue cells, constitute the framework of the stroma on which a collagenous deposit

subsequently occurs. *Endothelial cells* (those lining blood and lymph vessels) play but a small part in carcinoma. Polynuclear leucocytes and giant cells are also only slightly in evidence. *Elastic tissue* disappears in all areas of connective tissue cell proliferation, whether this is associated with a definite inflammatory state or with the connective tissue changes that are going on in a carcinomatous area. This disappearance is permanent—i. e., there is no regeneration of the elastic fibres when the cell proliferation has departed and fibrosis has supervened. This applies equally to the older parts of the stroma of primary carcinoma and the fibrotic stage of chronic granulomatous inflammation. In certain conditions, however, of chronic irritation which fall short of producing cell proliferation in the connective tissues, yellow elastic tissue may be increased by the deposition of a granular elastin around the old fibres. This is seen in some simple irritative states as well as in isolated areas in the stroma of carcinoma.

## 2. Pregnancy and Certain Medical Diseases.

—French, in the third of his Goulstonian lectures, takes up the influence of pregnancy on the commoner fevers. Generally speaking, the pregnant state seems to confer some degree of immunity, the reverse being true of the puerperium. *Typhoid fever* may begin at any period of the pregnancy, and its course is precisely similar to its course in other cases. Pregnancy has no influence on the severity of the illness, nor upon the prognosis as regards the mother. Premature ending of the pregnancy may occur at any time, this depending more on the month of the pregnancy than on the day of the fever. The mother seems to suffer very little from labor; the additional strain does not make her worse, and she experiences considerable relief. The uterus involutes just as usual, and the fever runs its ordinary course. Turning now to the fœtus, it has been definitely shown that typhoid bacilli can cross the placenta, reach the child, and be recovered from the child's tissues after birth. It is not yet known whether the child produces its own agglutinins or receives them from the mother. In a few cases definite ulceration of the fetal Peyer's patches has been noted, but such macroscopic lesions are quite the exception. It is impossible to say if the child will have a natural immunity to typhoid fever if it lives, but there is considerable evidence that such a child will suffer in other ways. If the child's life is a material consideration it is very risky to allow it to remain in utero beyond three weeks from the beginning of the typhoid fever. With each week of the fever the chances that the child will become infected with typhoid bacilli rapidly increase. *Smallpox* is transmissible from the mother to the fœtus. The degree to which the latter is affected is very variable. The stage of the eruption in the child may be almost identical with that in the mother. The eruption goes through a pustular stage in the unborn child just as it does in the adult, and the lesions are even larger. The duration of the eruption on the skin of the child may be much longer than usual. The father may have smallpox at the time of conception, the mother may show no sign of the disease, and yet the child may have it in utero. Cases of fetal scarlet fever, measles, whooping cough, cholera, malaria

and even cerebrospinal meningitis have been recorded. Diphtheria is particularly virulent in pregnant women. The laryngeal form of the disease is very common, and the mortality is great if antitoxine is not used. Plague is no worse in pregnancy than in ordinary cases, except that it usually terminates the pregnancy. If lobar pneumonia develops early in the pregnancy, the prognosis is about the same as regards the mother as for other patients of the same age. But if the pneumonia develops during the second half of pregnancy, the probability is that the latter will be terminated in two thirds of the cases, and the chances of the mother surviving will be greatly diminished. Diabetes mellitus is by no means incompatible with pregnancy, and there is seldom any reason for interference.

5. **Duodenal Ulcer.**—Broadbent states that duodenal ulcer may be distinguished from gastric ulcer by the seat and character of the pain, the indefinite relation of both pain and vomiting when this occurs to ingestion of food, and the absence of hæmatemesis. Melena in association with pain in the right hypochondriac region is very significant. A history of chronic indigestion occurring after middle life may suggest malignant disease of the stomach, but the chronicity and intermittency of the symptoms which may have lasted some years, and absence of severe emaciation and cachexia, usually enable a correct diagnosis to be made. In doubtful cases a test meal is of great value; in duodenal ulcer there is often excess and seldom absence of free hydrochloric acid. In all cases, before considering operation, care should be taken to exclude the possibility of gastric crises from locomotor ataxia.

## LA PRESSE MEDICALE

April 26, 1908.

1. Prophylaxis of Nervous Diseases of the Dietetic Foundation, By P. LONDE.
2. Epidemic of Paratyphoid Fever, By COLLIN and L. FORTINEAU.

1. **Prophylaxis of Nervous Diseases.**—Londe declares that there are four sorts of ætiological factors in the production of mental and nervous diseases: 1, Heredity; 2, accidental causes, including emotions, traumatism, physical and mental overwork; 3, specific diseases; and 4, digestive troubles or non-specific diseases. In the fourth class of cases, which includes a large variety of different diseases, attention to the diet has proved of marked prophylactic value.

2. **Paratyphoid Fever.**—Collin and Fortineau use the term paratyphoid fever to denote an infection distinct from that of enteric fever, produced by paratyphobacilli.

## LA SEMAINE MEDICALE

April 26, 1908.

Paralysed Addison's Disease.

## MUENCHENER MEDIZINISCHE WOCHENSCHRIFT

April 28, 1908.

1. Paralysed Physiological Experiments on Men and Animals, By WEISS.
2. New Facts as to Virus in the Treatment of Paratyphoid Processes, By MICHOU and PIERRE.
3. Concerning Recent Views Towards the Improvement and Simplification of Disinfection of the Skin, By von BALTUS.

4. The Symptomatology and Etiology of Barlow's Disease, By ESSER.
5. The Question of Metatyphus, By NIETER.
6. Dietetic Nutrient Preparations Before the Forum of the Specific Precipitation, By HORIUCHI.
7. The Meat Juice "Puro," By GERET.
8. The Treatment of Perityphlitis, By ALBU.
9. The Question of Sanatorium Treatment and the Indications for the Same, By FRANKENBURGER.
10. A Case of Poisoning After the Use of Thiosinamin, By GROSSE.
11. The Direct Inspection of the Mucous Membrane of the Stomach, By RIEHL.
12. A New Test for the Comparison of Sources of Actinic Rays, By AXMANN.
13. Technique of X Ray Photography, By DAVIDSOHN.
14. A Simple Aid to Comfort During Labor, By HEKZBERG.
15. An Improved Hypodermatic Syringe, By FAULHABER.
16. Concerning Karell's Treatment of Serious Circulatory Disturbances and the Treatment of Obesity (Concluded), By JACOB.
17. The Genesis of Gallstones, By BACMEISTER.
18. Obituary of Professor Gustav von Hüfner, By BURKER.

2. **Treatment of Purulent Processes.**—Müller deals with the theoretical and experimental part of the subject of controlling purulent processes by the addition of large quantities of blood serum and fluids rich in antiferments to the focus of suppuration, while Peiser speaks of the clinical aspects of the same subject. They allege that this method is a simple, effective increase of the physiological protective powers of the organism.

5. **The Question of Metatyphus.**—Nieter is convinced by the result of his researches that the typhus and metatyphus bacilli that have been described are accidental, and that there is no real difference between them.

8. **Treatment of Perityphlitis.**—Albu deals with the medical treatment of acute perityphlitis, and then of the chronic form. In the treatment of acute perityphlitis he considers that, in the hands of the experienced physician, opium is certainly less dangerous than castor oil, but the traditional dogma of the textbooks that perityphlitis should be treated with opium he considers obsolete.

9. **Sanatorium Treatment.**—Frankenburger refers entirely to the treatment of tuberculosis in this paper.

11. **Direct Inspection of the Mucous Membrane of the Stomach.**—Riehl remarks that, by means of the gastroscope, with the stomach filled with water, it is possible: 1. To see clearly the greater part of the mucous membrane of the healthy stomach, and study the normal coloring, the folds, and the movements of the walls of the stomach; 2. to illuminate the greater part of the lesser curvature and the region of the pylorus; and 3. to observe the appearance of cancer, which, in a carcinoma of the lesser curvature, presents a greenish surface. An examination of the stomach should be preceded by an application of a ten per cent. solution of cocaine to the throat.

16. **Karell's Treatment.**—Jacob, after reporting a series of cases of obesity treated in the way described last week, says that this method is contraindicated only in cases in which there is degeneration of the cardiac muscle, whether from coronary sclerosis, arteriosclerosis of the bulb of the aorta, or

chronic inflammatory processes in the cardiac muscle, or fat, so far advanced that even under the most favorable conditions the heart cannot recover.

#### BERLINER KLINISCHE WOCHENSCHRIFT

April 27, 1908.

1. Pericardial Friction Sounds with Synechia of the Pericardium, By ERICH RICHTER.
2. Concerning the Results of Modern Investigations into Sympathetic Ophthalmia, By GEORG LENZ.
3. Interference with Respiration and with the Introduction of Food by a Large Thymus in a Child Ten Weeks Old. Operation. Recovery, By WILLY HINRICHS.
4. Oxidation of Sugar, By GEORG ROSENFELD.
5. The Care of Tuberculosis (Sanatoria?), By AUFRICHT.
6. Regarding the Question of the Permanent Results of Sanatoria, By B. FRÄNKEL.
7. Wassermann's Syphilis Reaction, By J. BAUER.
8. Concerning Local Sensitiveness of the Conjunctiva to Tuberculin, By SIGISMUND COHN.

1. **Pericardial Friction Sounds with Synechia of the Pericardium.**—Richter reports a case in which a diagnosis during life of fresh pericarditis was made because of the appearance and disappearance of pericardial friction sounds, but on autopsy the pericardial sac was found to have been totally obliterated by adhesions which showed no signs of recent inflammation.

2. **Sympathetic Ophthalmia.**—Lenz says that recent anatomical studies of sympathetic ophthalmia have demonstrated that there is a specific anatomical picture which renders possible a distinction of this from other forms of chronic uveitis, that only such eyes as present this specific picture are sympathetic, that the specific infiltration of the first diseased eye is identical with that of the second eye to be involved. Finally he states that, while important advances have been made in the knowledge of sympathetic ophthalmia, much still remains obscure, and with many an injured eye we are in doubt whether there is danger of sympathetic inflammation or not.

4. **Oxidation of Sugar.**—Rosenfeld in this contribution considers the liver as the central organ of metabolism.

8. **Local Sensitiveness of the Conjunctiva to Tuberculin.**—Cohn states that a single instillation of a one per cent. solution of old tuberculin while it does not induce a visible reaction does cause a hypersensibility which is manifested in two ways: 1, By an ability to react to a second instillation of a one per cent. solution of tuberculin with evident signs of inflammation; 2, by an ability to draw tuberculin from the circulating blood and then to react to this. These peculiarities are strong locally and confined to the conjunctiva which has been used for instillation. A lapse of at least five days is usually necessary for the development of these peculiarities. The maximum of the hypersensitiveness is reached about the beginning of the third week. It is possible, but not proved, that the artificial hypersensitiveness is a sign of latent tuberculosis.

#### LA RIFORMA MEDICA

April 6, 1908.

1. On Very Light Forms of Malta Fever in Naples, By ARNALDO CANTANI.
2. On the Therapeutic Uses of Viscum, By CARLO FEDELLI.
3. Contribution to the Study of the Pathogenesis of Cystic Kidney (Concluded), By DOMENICO TADDEI.

**1. Mild Form of Malta Fever in Naples.**—Cantani studies the very mild cases of Malta fever which came under his observation recently in Naples. Shaw was the first to describe in detail an ambulant form of Malta fever. This author examined 525 dock laborers on the island of Malta and found that seventy-nine showed a positive agglutination reaction. In twenty-two of these laborers, Shaw found the micrococcus of Malta fever in the blood and the urine. The ambulant form of Malta fever has been prevalent in Naples for some time, and Cantani urges the necessity of bacteriological examinations in suspicious cases, although he realizes that in the mild cases the patient will rarely submit to medical treatment. Most cases which he had under observation occurred in several members of one family. Thus he reports five cases in one family, of which three were of medium gravity, and one was fairly severe. In another family, a young woman was attacked first, her fever lasting forty days; then followed two sisters, then a brother. Several other similar examples are reported by the author, the total cases numbering thirteen, and in each case the bacteriological examination of the blood showed the agglutination reaction. Ambulant cases of Malta fever are much more frequent than many physicians suppose. As we receive annually a large number of immigrants from Naples, some of them may import Malta fever, even in this attenuated form, and it might be well for the health authorities in the various ports to be on the lookout for these cases.

**2. Therapeutic Uses of Mistletoe.**—Fedeli reviews the literature which has recently been published concerning the revival of mistletoe as a therapeutic agent. A number of articles have been published on this subject, particularly that of Gauthier (*Gazette des Hôpitaux*, October 17, 1907). The preparations used by Gauthier were an aqueous extract of mistletoe in doses of from 20 to 30 c.c. in twenty-four hours; a syrup, in doses of from 10 to 15 teaspoonfuls in twenty-four hours, etc. *Viscum album* has been found by Chevalier and Gauthier to lower the blood pressure, to accelerate the pulse, and in large doses to kill by paralyzing the heart and causing hemorrhages in the gastrointestinal tract, the endocardium, etc. Gauthier recommends mistletoe in arteriosclerosis with high tension pulse. Fedeli, in the present article, reports an interesting case of severe acute nephritis in a physician, in whom he used the extract of mistletoe, beginning with 6 c.c. and increasing to 30 c.c. daily. The effect was excellent, the albumin diminishing rapidly until, at the end of the month, there was but a trace. It does not appear clearly, however, whether the recovery was due to the mistletoe or to the milk diet which the patient maintained. In another case, with a history of uræmic attacks, the extract of mistletoe was administered with good results. In a third case of very severe nephritis in a young man who had slight arteriosclerosis, hypertrophy of the left ventricle, œdema, scanty urine, rich in albumin and casts, the extract of mistletoe was given in increasing doses, with the result that the albuminuria rapidly diminished. This patient died of uræmia. While the number of cases in which mistletoe was used was small, the author thinks that in selected cases *Viscum album*

will give good results in the treatment of nephritis. The remedy acts best in cases in which there is a certain degree of increased arterial pressure and of arterial spasm. In some cases, in which the lesions are too far advanced, especially in cases of chronic acute nephritis, not much benefit can be expected. On the other hand, in cases in which parenchymatous lesions predominate, *Viscum album* will be found to have a favorable effect.

April 13, 1908.

1. Observations on an Involution Form and on Cultures of *Trypanosoma Brucei*, By GENARO FUSCO.
2. Syphilitic Fever? By ANGELO CECONI.
3. A Case of Dupuytren's Disease, By A. B. GIANASSE.

**1. Cultivation of Trypanosoma.**—According to Fusco, the best medium for the cultivation of trypanosoma is a mixture of three parts of blood and one part of a two per cent. solution of sodium oxalate. In this medium, the red blood corpuscles remain unaltered for a long time at a temperature of 22° C. The trypanosoma in this medium preserves its characteristic shape for some time and rarely shows the rounded involution forms which are so frequently seen in other culture media. Some involution forms, however, with a large and a small nucleus each, and with a long filament, are noted in these cultures. Here and there isolated macronuclei are found. In a mixture of one part of a two per cent. solution of ammonium oxalate and of three parts of guinea pig's or white rat's blood, the trypanosoma develops in rounded forms with a large and small nucleus and a very long filament, while the protoplasm is but faintly staining and the large nucleus appears fragmented. In this medium the red blood corpuscles remain unaltered for a long time. If these involution forms of trypanosoma, which are met with in the blood and the organs of animals that died of trypanosoma infection, and in these various culture media be compared with the bodies studied by Leishman in kala-azar, it will appear clearly that there is no difference between them. Under the name of kala-azar or dumtum fever, there is a disease which flourishes in India, especially in the neighborhood of Calcutta, and is characterized by severe emaciation, an irregular remittent fever, and an enormous enlargement of the spleen. At first these cases are taken for malaria, yet no parasites of malaria can be found, nor does quinine relieve the symptoms. The patients suffer from a progressive muscular atrophy and a blackish pigmentation of the skin, as well as from occasional œdemas of the feet and lungs. Leishman found in the spleens of the patients that had died from this disease a large number of bodies bearing characteristics of the trypanosoma, but which he named the piroplasma of Donovan, which name was later changed to *Leishmania Donovanii*. The exact nature of this body has not yet been determined, but Rogers was able to transform Leishman's bodies into trypanosomas in the course of cultivation for ninety-six hours. From these studies it appears very probable that Leishman's bodies are involution forms of trypanosoma. The present author proves that identical bodies exist in the blood and the splenic pulp of animals that died of trypanosoma infection, and also in various culture media in which trypanosoma grows. In other words, Leishman's bodies, under special culture conditions, may

assume the appearances of trypanosoma, and *vice versa*.

### Proceedings of Societies.

#### THE ASSOCIATION OF AMERICAN PHYSICIANS.

*Twenty-third Annual Meeting, Held in Washington, May 12 and 13, 1908.*

The President, Dr. JAMES TYSON, of Philadelphia, in the Chair.

(Continued from page 957.)

**Nonfatal Coma in the Course of Diabetes.**—Dr. C. N. B. CAMAC, of New York, reported a case of well marked diabetes in an adult who had been under observation for six months. The patient became irascible, and accompanying this phenomenon the urine became lower in specific gravity and the quantity of glucose excreted was somewhat lessened. Diabetic acid disappeared and oxybutyric acid did not appear; but the coma, which was fully developed, was not accompanied by an increase of the urinary ammonia until the consciousness was returning; then it increased quite decidedly. Later the patient became hemiplegic, the blood pressure rose to between 170 and 180 mm., and death ensued. At the necropsy intracranious pancreatitis, chronic nephritis, cerebral softening, and general arteriosclerosis were the important lesions discovered.

Dr. S. SOLIS-COHEN, of Philadelphia, referred to a case in which the patient recovered from coma and lived twenty years. Six years before death glucose disappeared from the urine and was replaced by albumin. He referred to several cases in which recovery from coma had occurred.

Dr. JAMES EWING, of New York, said that he interpreted the case reported by Dr. Camac as one of genuine diabetic coma without acidosis.

Dr. THEODORE C. JANEWAY, of New York, said that it was difficult to judge whether the case was one of coma from diabetes, from uræmia, or from gross cerebral disease.

**The Atrioventricular Bundle, with a Report of a Case of Acute Ulcer on the Interventricular Septum.**—Dr. WALTER B. JAMES, of New York, exhibited a specimen in which there was a good sized ulcer involving the heart muscle in the region of the interventricular wall, which would involve the bundle of His. The patient was a man, aged sixty years, who had suffered from malignant endocarditis. He had a slow pulse, and simultaneous jugular and carotid tracings showed dissociation; the ventricles were beating at a rate of 50 a minute and the auricles at a rate of 100. There was at no time a Stokes-Adams syndrome. The speaker was of the opinion that many cases were reported as examples of heart block which, on critical analysis, appeared to be cases of extra systole. Reduplication of the first sound of the heart was the first indication of myocardial disease or of endocardial disease, or of both, in such diseases as acute rheumatism, for example.

**Intraventricular Systole.**—Dr. H. A. STEWART, of Baltimore, exhibited an instrument designed to give tracings of the events taking place at the valve orifices during their closure. By the use of this in-

strument he had been able to record some tracings in dogs, and they showed that the aortic orifice was closed during diastole, at least in part, by muscular action. It was further found by careful dissection that the aortic valve leaflets were attached to the ventricular muscle, and that this muscle was active in closing the aortic opening. He described the development of an aortic diastolic murmur in the course of certain diseases, such as typhoid fever and exophthalmic goitre, which disappeared as the convalescence of the patient progressed. Such a murmur he would interpret as depending upon the failure of the muscle to properly occlude the aortic opening during diastole.

**Heart Sounds Heard Early in Diastole.**—Dr. WILLIAM S. THAYER, of Baltimore, described a sound which he had often heard in early diastole while listening to the hearts of dogs which were being experimented upon. He had also heard similar sounds in examining children, and in quite normal individuals. The sound was soft and was associated with a visible shock, and sometimes with a palpable shock; it was increased by turning the patient on the left side. In five out of six cases the aortic murmur was accompanied by an "h" wave on the jugular tracing. The murmur described was similar in character to a murmur heard early in diastole in cases of mitral stenosis and in cases of galop rhythm. It was probably an event closely associated with the rapid entrance of the blood into the ventricle early in diastole. Dr. Thayer considered that the best hypothesis for the explanation of the sound was that during the first inrush of blood through the mitral and tricuspid orifices the valves were suddenly brought into tension, thus giving rise to the sound described. It was not uncommon in the normal heart or in the hearts of young individuals in early diastole after the second sound occurred.

Dr. A. A. ESHNER, of Philadelphia, said that he had heard such a sound as that described by Dr. Thayer. He had thought that the condition of the entrance of the blood into the ventricles during diastole was proper for the production of such a sound.

Dr. THAYER said that an analogous sound could be heard in cases of aortic insufficiency.

**Anæmia in Children.**—Dr. M. H. FUSSELL, of Philadelphia, reported the case of a boy, aged thirteen months, who had had a severe intestinal disturbance at the age of eight months. He was pallid and had an abdominal tumor, which was proved to be an enlarged spleen, enlarged lymph nodes, with myelocytes in the blood. The patient died. He considered the case to be one of the anæmia infantum pseudoleuchæmia of von Jaksch. He reported the case of a girl, aged seven years, who vomited blood. She was anæmic, and had an enlarged heart with a mitral presystolic and a mitral systolic murmur. The child died after a large hæmorrhage from the stomach. The examination of the blood showed 1,275,000 erythrocytes, 6,000 leucocytes, and twenty per cent. of hæmoglobin. At the necropsy the liver was found enlarged, pale, and pink in color; there was thrombosis of the hepatic vein; the spleen was enlarged; there were dilated œsophageal veins, from which the hæmorrhage had occurred. In this case the diagnosis was that of splenic anæmia dependent upon sepsis. The third patient was very anæmic,

presented a lemon yellow color, and suffered from rhachitis. There was an enlarged liver with an enlarged spleen. The blood examination showed 1,600,000 erythrocytes, 24,160 leucocytes, and twenty-four per cent. of hæmoglobin. There were forty per cent. of polymorphonuclear neutrophils, 40.1 per cent. of lymphocytes, and two per cent. of myelocytes in the circulating blood. The patient died of right apical pneumonia. The examination of the bone marrow showed a marked increase in the lymphocytes. This case was looked upon as an example of anæmia infantum pseudoleucæmia.

Dr. J. P. CROZER GRIFFITH, of Philadelphia, said that in his opinion the so called von Jaksch's anæmia was infantile leucæmia.

**Splenic Anæmia, Splenectomy, Recovery.**—Dr. MORRIS J. LEWIS, of Philadelphia, reported a case of splenic anæmia in which splenectomy had been done with recovery, and in which he had had the opportunity of studying the blood for seven years, four years before the removal of the spleen and three years after the operation. The patient had had a moderate anæmia, with continuous symptoms of dyspepsia. There was a sudden profuse hæmorrhage, for which gastroenterostomy was done with benefit on the theory that an ulcer had caused the bleeding. Later, splenectomy was done and the operation was followed by pleural effusion, pericarditis, and abscess in the wound. These inflammatory complications interfered with the accurate study of the blood, but there was marked eosinophilia, which persisted three years after the removal of the spleen. There was but little change in the percentage of lymphocytes in the blood.

Dr. JAMES B. HERRICK, of Chicago, and Dr. A. B. BLACKADER, of Montreal, referred to cases of splenectomy.

**The Relation of Urobilinuria to the Presence of Bile Pigment in the Blood.**—Dr. LEWIS A. CONNER and Dr. J. C. ROPER, of New York, had found that as a rule the amount of urobilin in the urine corresponded to the amount of bile pigment in the blood serum. In order to determine the amount of bile pigment in the blood, they employed a modified Gmelin's test as recommended by Gillert and Herscher. They found that in certain cases very high amounts of bile pigment in the blood were not accompanied by any urobilin in the urine. In certain cases of pneumonia there was urobilin in the blood serum without bile pigment. This phenomenon might be due to some action of the pneumococcus.

Dr. JAMES EWING, of New York, said that in puerperal eclampsia urobilin was found in the blood serum. He attributed the occurrence to a disorder of the hepatic function.

**The Relation of the Auditory Centre to Aphasia.**—Dr. ADOLPH MEYER, of New York, demonstrated the lesions found in the auditory centre in the superior temporal convolution of the cerebrum in certain cases of aphasia with the aid of admirable lantern slides and photographs of reconstructions. The specimens showed that in certain cases of aphasia there was an extensive lesion in the cortical auditory centre.

**The Pathology of Exophthalmic Goitre as Related to Clinical Symptoms, Being a Study of**

**Nearly 300 Cases Operated on by Dr. C. H. Mayo.**—Dr. LOUIS B. WILSON, of Rochester, Minn., exhibited numerous lantern slides showing the gross and microscopical appearance of the thyroid body, and the appearance of the patient suffering from exophthalmic goitre of varying degrees of severity. He divided the operative cases into the following groups: 1, A small intraalveolar parenchyma increase, with a small amount of thin secretion. 2, A large amount of intraalveolar increase, with a large amount of thin secretion. 3, A large amount of intraalveolar parenchyma increase, with a large amount of thin secretion and beginning degeneration. 4, Old intraalveolar parenchyma increase, with a large amount of thick secretion and advanced degeneration. 5, A small amount of multialveolar parenchyma increase, with a small amount of thin secretion. 6, A large amount of multialveolar increase, with a large amount of thin secretion. 7, A large amount of multialveolar parenchyma increase, with a large amount of thin secretion and beginning degeneration. 8, Old multialveolar parenchyma increase, with a large amount of thick secretion and advanced degeneration.

Dr. WILLIAM H. THOMSON, of New York, said that Graves's disease and exophthalmic goitre were not synonymous.

Dr. WILLIAM H. WELCH, of Baltimore, said that it was well known that the dogs in the Great Lake region showed parenchymatous changes in their thyroid glands, which disappeared on feeding the animals with iodine. In the neighborhood of Baltimore such changes were rarely met with.

Dr. J. G. ADAMI, of Montreal, said that the paper was an admirable one from the point of view of correlating the clinical with the pathological manifestations of enlargement of the thyroid gland with exophthalmos and tachycardia.

Dr. WILSON said he hoped that in time we should get away from the terms exophthalmic goitre and Graves's disease, and should designate all cases presenting the symptoms of enlarged thyroid, exophthalmos, and tachycardia as cases of hyperthyroidism.

**Erythromelalgia, Raynaud's Disease, and Allied Conditions in Their Relation to Vascular Diseases of the Extremities.**—Dr. B. SACHS and Dr. L. BUEGER, of New York, exhibited lantern slides to illustrate the opinion that Raynaud's disease and erythromelalgia were due to thrombosis of the veins of the lower extremities. The proper name for the condition, according to the writers, was thromboangitis obliterans. The two diseases were closely related to each other and to gangrene and intermittent claudication. There were, furthermore, some cases of loss of muscular power in old persons, which were diagnosed as cases of senile paraplegia, which were due to interference with the circulation in senile bloodvessels. The process was an ascending obliterative one, which began in the tributaries and the branches of the dorsalis pedis and plantar vessels and ascended until all the arteries and veins became occluded. In many of the vessels the histological preparations showed that the central clot was tunneled by small new vessels, which prevented the occurrence of gangrene. There was, in addition to the thrombotic process, perivascularitis with

proliferation of the connective tissue, matting vessels and nerves together. In other cases there was associated atheroma.

(To be continued.)

### Letters to the Editors.

#### THE WHITMAN BRACE.

126 EAST THIRTY-FOURTH STREET,  
NEW YORK, May 25, 1908.

#### To the Editors:

In an article entitled *The Restoration of the Normal Balance of the Foot*, by Dr. Abbott and Dr. Pingree, which appeared in the last issue of the *Journal*, an illustration of a Whitman brace is presented showing how, when unsupported by the shoe, it permits the front of the foot to slide away from it. As this brace can only be used in a shoe, the pertinence of the illustration is not apparent. Dr. Whitman has always insisted upon a proper shoe as an essential adjunct of the brace, and that the foot does not fall away from the brace when properly applied may be demonstrated by observation, more particularly by the imprint which is made by it on the inner margin of the entire foot.

The brace advocated by Dr. Abbott and Dr. Pingree is, from the Whitman standpoint, defective in that it does not provide lateral support; thus it cannot control the inward bulging significant of abduction, which is the characteristic of all grades of weak foot. The writers say that, if the sole plate is sufficiently arched and if the foot may be so balanced upon it that it does not slide away, abduction is prevented. Granting this, for the sake of argument, it is prevented indirectly by pressure on the soft tissues of the sole. It seems far more reasonable to prevent abduction directly, by lateral support, and thus to relieve the sole from abnormal pressure of the arch of the brace. Thus both lateral and direct support may be utilized to check deformity. Lateral pressure has another great advantage in that, on the one hand, it prevents the toeing out which is one of the principal predisposing causes of the weak foot, and, on the other hand, it induces the instinctive drawing away of the foot from this pressure toward a better attitude. This attitude, which, when confirmed by posture and by exercise, assures the cure, is aided by the slight leverage action of the brace, if properly adjusted. The lateral support and the leverage action are the distinguishing features of the Whitman brace, and that it is superior to those of the simple or negative type favored by the writers is confirmed, not only by observation of its effects, but by the testimony of intelligent wearers of the brace as well.

The advantage of taking the cast by the Whitman method is that the entire foot is reproduced instead of the irregular fragment illustrated in the article. Thus the changes to be made in the cast, upon which its fit and efficiency in some degree depend, may be made more intelligently. Overcorrection of the deformed foot, objected to by the writers, is, as in the treatment of any other deformity, considered an essential step in functional cure. It may be assumed that the majority of those

who use the Whitman brace have the advantage of having learned the details of its application by actual demonstration, after which the principles of treatment, of which it is an essential part, may be much better appreciated.

JOHN CARLING.

### Book Notices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

*The Bacteriology of Diphtheria.* Including Sections on the History, Epidemiology, and Pathology of the Disease, the Mortality Caused by It, the Toxines and Antitoxines, and the Serum Disease. By F. LOEFFLER, M. D., LL. D.; ARTHUR NEWSHOLME, M. D., F. R. C. P.; F. B. MALLORY, M. A., M. D.; G. S. GRAHAM-SMITH, M. A., M. D., D. P. H.; GEORGE DEAN, M. D.; WILLIAM H. PARK, M. D., and CHARLES F. BOLDUAN, M. D. Edited by G. H. F. NUTTALL, M. D., Ph. D., Sc. D., F. R. S., Quick Professor of Biology in the University of Cambridge, Fellow of Christ's College, and G. S. GRAHAM-SMITH, M. A., M. D., University Lecturer in Hygiene, Cambridge. Cambridge: University Press, 1908; London: H. K. Lewis; Leipzig: F. A. Brockhaus; New York: G. P. Putnam's Sons; Bombay and Calcutta: Macmillan & Co., Ltd. Pp. xx-718. (Price, \$7.50.)

This comprehensive treatise opens with several single page biographical sketches of the men whose names are so intimately associated with the history of diphtheria, namely, Bretonneau, Loeffler, Behring, and Roux. The text proper is divided into six sections, each written by an accepted authority, as follows: History of the disease, Professor Loeffler; epidemiology, Arthur Newsholme; pathology, Frank Mallory; the diphtheria bacillus, G. S. Graham-Smith; immunity, George Dean; mortality and serum treatment, William H. Park and Charles F. Bolduan.

The historical account, by Loeffler, quickly brings the reader to that wonderful epoch in medicine signalized by the discovery of the diphtheria bacillus, its toxine, and its antitoxine. The logical development of this phase of the subject is well set forth, and the important work done in this country is duly credited.

Newsholme, in his study on the epidemiology, concludes that "diphtheria is relatively more a continental than an insular disease," a statement which the reviewer believes is open to question. The author also gives interesting data on the epidemic and pandemic outbreaks of the disease, and then inquires into the reason for these occurrences. He finds this in the relation of the disease to rainfall, and says that "diphtheria only becomes epidemic in years in which the rainfall is deficient, and the epidemics are on the largest scale when three or more years of deficient rainfall immediately follow each other." It is interesting to note that Park and Bolduan, in discussing the same point, are rather skeptical concerning such a connection.

The section on the pathology of diphtheria, by Professor Mallory, is very complete, and is based on a study of 251 cases of the disease which came to autopsy in the Boston City Hospital. The general distribution of the local lesion was about the same as in other large series of cases. It is remarkable that a definite membrane occurred in but 148

of the 251 cases. Diphtheria bacilli could almost always be found microscopically in early cases when a definite membrane was present. They were not found in living tissue or on the surface of normal epithelium or even in those places which would be regarded as the primary lesion of the disease. Mallory therefore believes that the beginning of the lesion is probably due to the toxic action of bacilli growing in the fluids of the mouth or throat. When necrosis is once produced, the necrotic tissue and the membrane on its surface form a suitable culture medium. In this series of cases it was found that eighty per cent. of the patients who had been intubated showed bronchopneumonia. In cultures made from the lungs, streptococci were just about as frequent as diphtheria bacilli.

The section on the diphtheria bacillus, by G. S. Graham-Smith, is a veritable mine of information, and constitutes a welcome discussion of our present knowledge of the subject. The author points out the difficulties which have arisen in consequence of the loose nomenclature, and particularly owing to the indiscriminate use of the term "pseudodiphtheria bacillus." He then gives a minute description of the diphtheria bacillus and of Hoffmann's bacillus, and their relation to one another. In a special chapter on the diagnosis he also considers other diphtherialike organisms, among them the xerosis bacillus. Hoffmann's bacillus is held to be a distinct species, and not merely a nonvirulent variety of the diphtheria bacillus. There is an instructive table showing the action of diphtheria bacilli from various sources on different sugars and carbohydrates in the serum water medium of His and in broth. Space does not permit of even a mention of all the other excellences of this section.

Dean gives a scholarly account of immunity in diphtheria, first tracing the development of the subject to the time of the discovery of the diphtheria toxine. He then discusses the toxine in detail, and gives a clear picture of Ehrlich's conceptions of the nature of the diphtheria poison. The production of antitoxine is discussed very fully, and mention is made of Gibson's method of concentrating the antitoxic globulins. Ehrlich's theory concerning the toxine-antitoxine reaction receives considerable attention, and the conflicting views of Ehrlich, Arrhenius, and Bordet are clearly set forth. Dean wisely refrains from expressing an opinion as to which is nearest the truth.

The final section, by Park and Bolduan, gives a scientific and clear exposition of the manner in which statistics may be used to study the influence of treatment on the mortality from diphtheria. The various sources of error in previous computations are pointed out and avoided in the present study. This is based on the mortality returns from nineteen large cities, both here and abroad, and comprises statistics embracing a total population, in 1905, of over 23,000,000. One of the curves is particularly interesting. It shows the sudden drop in mortality which occurred in 1895, when antitoxine had just been introduced. The same authors have a chapter on serum sickness, and report excellent results following the use of concentrated and purified antitoxine made according to the Gibson process. In their discussion on the theory of the serum

rashes they refer to the work of Pirquet and Schick.

The book closes with an excellent bibliography, extending over more than sixty pages and well arranged typographically. Altogether this volume presents a convenient storehouse of authoritative information on diphtheria, and should accordingly be heartily welcomed by scientific workers everywhere. The reviewer recommends the book to all who wish to obtain accurate data on this important subject.

*Bier's Hyperæmic Treatment in Surgery, Medicine, and the Specialties. A Manual of Its Practical Application.* By WILLY MEYER, M. D., Professor of Surgery at the New York Postgraduate Medical School and Hospital, etc., and Professor Dr. VICTOR SCHMIEDEN, Assistant to Professor Bier, University of Berlin, Germany. Illustrated. Philadelphia and London: W. B. Saunders Company, 1908. Pp. 209. (Price, \$3.)

Although many essays have appeared in our medical periodicals, and still many more papers on this subject have been read before medical societies, treating of Bier's *Stauungshyperæmie*—hyperæmic treatment, as translated usually; dammed circulation, as proposed by Ewart, of England—there has not been published so far an authoritative full account of the treatment. The profession will certainly welcome this addition to our literature.

Bier stated some years ago: "Hyperæmic treatment, used by Nature so extensively in combating all kinds of lesions, is destined to be far more employed than has hitherto been done." Our authors say rightly that it should not be assumed that the millennium has been introduced with this treatment. The physician must strictly follow the directions as laid down by Bier and his school, must be absolutely sure of the pro and contra indications, and must be thoroughly familiar with the technique. Then, and then alone, good results will be achieved. Hyperæmic treatment is not a panacea, and because it has been accepted as such by many, failures have been so often reported.

The profession will now have the means of trying this method of treatment exactly, and may accept or decline it.

*Surgery: Its Principles and Practice.* By Various Authors. Edited by WILLIAM WILLIAMS KEEN, M. D., LL. D., Emeritus Professor of the Principles of Surgery and of Clinical Surgery, Jefferson Medical College, Philadelphia. Volume III. With 562 Text Illustrations and 10 Colored Plates. Philadelphia and London: W. B. Saunders Company, 1908. Pp. 1132.

The first chapter in the present volume is on the surgery of the head, by Dr. Harvey Cushing, who gives an admirable presentation of the subject and states most truly that the prevailing impression in regard to the dangers and general utility of cerebral surgery, which hampers its advance, is due, in large measure, to the unsuccessful attempts of the untrained and inexpert.

The surgery of the neck is described by Dr. E. Wally Andrews, who favors Cole's method in operating in this region.

Albert Kocher reviews the diseases of the thyroid gland, and believes that surgical is superior to any other form of treatment in exophthalmic goitre, his own experience giving eighty-five per cent. of recoveries, while in simple goitre the largest share of treatment belongs to the internal.

The surgery of the nose and its accessory sinuses

is described by Dr. Harmon Smith in a brief and practical manner.

Dr. George E. Brewer has written the chapters on the surgery of the larynx and trachea and of the thorax.

The surgery of the breast is described by Dr. John M. T. Finney, who advises the complete extirpation of benign tumors, cysts, and malignant growths.

Mr. Edmund Owen is the author of the chapter on the surgery of the mouth, teeth, and jaws.

The surgery of the tongue is reviewed by Dr. John C. Da Costa in a somewhat brief fashion.

Dr. John C. Munro is the author of the chapters on the technique of abdominal surgery, on the surgery of the abdominal wall, and on the surgery of the peritonæum and retroperitoneal space. Necessarily these subjects are treated with brevity.

The surgery of the œsophagus is described by Dr. George Gottstein, who gives some interesting illustrations of findings of the œsophagoscope.

The chapter on the surgery of the stomach, by Mr. A. W. Mayo Robson, is one of the most satisfactory in the volume.

The chapter on the surgery of the liver, the gall-bladder, and the biliary duct is by Dr. William J. Mayo and Dr. Charles H. Mayo, and is a succinct presentation of the subject.

Mr. B. G. A. Moynihan is the author of the chapters on the surgery of the pancreas and of the spleen.

*Diseases of the Nose, Throat, and Ear.* Medical and Surgical. By WILLIAM LINCOLN BALLENGER, M. D., Professor of Otology, Rhinology, and Laryngology, College of Physicians and Surgeons, Department of Medicine, University of Illinois, etc. Illustrated with 471 Engravings and 16 Plates. Philadelphia: Lea & Febiger, 1908. Pp. viii-17 to 905.

This work, which includes also the relation of the accessory sinuses to diseases of the eye, is thoroughly abreast of the times in taking into consideration the latest advances of medical science, especially in pathology and surgical technique, almost encyclopædic in scope, and, if any criticism was to be made, rather more than necessarily full in detail. This completeness is welcome and valuable in the chapters on treatment and operations, and the work will be found an excellent reference handbook for this reason. There is rather too much theory and a tendency to generalizing in the chapters on aetiology, pathology, and principles of treatment, which somewhat lessens its value for the student and its usefulness as a textbook. The practical chapters are by far the best, and it is to be noted that Ballenger has given us an excellent account of major operations in this special field, such as extirpation of the larynx, excision of the external carotid, osteoplastic resection of the upper jaw, and the external operation for pharyngeal abscess, which are often relegated to general surgeons by specialists who are not fully sure of themselves. The illustrations are very numerous and some of them are excellent. This applies particularly to the diagrams and instructive schemata, and to the half tone cuts. Others, notably the many woodcuts from rather mediocre line drawings, are uniformly on too small a scale, and must, if judged by the present high

standard of medical illustrations, be said to be inferior.

*Christian Science, the Faith and Its Founder.* By LYMAN P. POWELL, Rector of St. John's Church, Northampton, Massachusetts. New York and London: G. P. Putnam's Sons, 1907. Pp. xviii-261.

The author's purpose has been to write a book in which the average man who is not a Christian Scientist can find the things he wants to know about its theory and practice. He concludes that the good in that cult is the good in other religions, and needs therefore no special emphasis; that the evil is distinctive and needs analysis and publicity to make it evident; and, finally, that it is perilous for people to commit themselves to this crude faith, that is "repudiated with indignation by historic Christianity and with contempt by science, without a clearer understanding than is common of its insecure foundations and its inevitable implications." The author has made a most painstaking and comprehensive study of the subject, and his presentation of the facts is cogent and forceful.

*Gonorrhœa. Its Diagnosis and Treatment.* By FREDERICK BAUMANN, Ph. D., M. D., Professor of Genitourinary Diseases in the Reliance Medical College and Instructor in Dermatology and Venereal Diseases in the College of Physicians and Surgeons, Chicago. Fifty-two Illustrations in the Text. New York and London: D. Appleton & Co., 1908. Pp. xii-206.

This book is a very good manual of the diagnosis and treatment of the gonorrhœal infections of the genitourinary tract of the male. The subject is treated of in a concise and clear manner. Gonorrhœa in the female is only so far taken into consideration as it affects the urethra (Chapter xiv). A very short chapter treats also of the "vaccination" therapy of gonorrhœa.

On page 125 is reproduced an illustration taken from the German, which still contains German nomenclature. Could not this be changed into English in future editions?

*Die Praxis der Hautkrankheiten.* Unna's Lehren für Studierende und Aerzte, zusammengefasst und dargestellt von IWAN BLOCH, Berlin. Mit einem Vorwort von Dr. P. G. UNNA in Hamburg. Mit 92 Abbildungen. Berlin und Wien: Urban & Schwarzenberg, 1908. Pp. 698. (Price, 18 marks.)

This volume represents, as its title indicates, a collection of the teachings of Professor P. G. Unna in the field of dermatology, and the field is covered very thoroughly. The work is prefaced with an historical review of the recognition and treatment of affections of the skin from the earliest times, the author making a brief reference to conditions in the different epochs in history. The physiological anatomy of the skin and hair is treated of concisely, yet comprehensively, in the opening chapter, the text being illustrated with numerous excellent engravings. The morphology, biology, and pathogeny of the skin and tissues are considered in the opening chapters, practically the rest of the book being devoted to diagnosis and treatment. For those who are familiar with the German language and who desire to inform themselves regarding approved modern methods of treatment, this encyclopædic work should prove especially helpful. It is particularly rich in formulas, as might be expected when the number of both internal and external applications

for the treatment of skin diseases is considered. It is a book which can be unhesitatingly commended to the general practitioner as well as to the specialist.

*Geschichte der Laryngologie in Würzburg.* Von Professor Dr. Otto SEIFERT, Würzburg: A. Stuber, 1908. Pp. 68. (Price, 3.50 marks.)

This little book is an interesting historical sketch of the development of the study of laryngology at the University of Würzburg, and it may well be applied to all German universities.

*Die Erkrankungen der weiblichen Geschlechtsorgane.* Von Hofrath Prof. Dr. R. CHROBAK und Hofrath Prof. Dr. A. VON RUTHORN in Wien. II. Theil Die Missbildungen der weiblichen Geschlechtsorgane. Mit 90 Abbildungen und 2 Tafeln. Wien und Leipzig: Alfred Hölder. Pp. 272.

This section of the author's extensive work on gynecology is devoted, as the title indicates, to the deformities and anomalies of the sexual organs, both external and internal. It is very copiously illustrated, and some of the illustrations are very good. The surgical methods for remedying these abnormalities are also given, and at the end of each chapter is a very extensive bibliography which shows the enormous literature which is available upon this subject.

#### BOOKS PAMPHLETS, ETC., RECEIVED

Linné's Dietetik. Pa Grundvalen af dels hans eget Originalkast till Föreläsningar: Lachesis Naturalis Quae Tradit Dietam Naturalem. Och dels Lärjungeanteckningar efter dess hans Föreläsningar: Collegium Dieteticum. Pa Uppdrag af Medicinska Fakulteten i Uppsala. Ordnad och utgifven af A. O. Lindfors. Uppsala: Akademiska Bokhandeln (C. J. Lundström), 1907. Pp. 248.

Bref och Skrifvelser af och till Carl von Linné. Med Understöd af Svenska Staten utgifna af Upsala Universitet. Första Afdelningen. Del I. Stockholm: Aktiebolaget Ljus, 1907. Pp. 341.

Experimentella Undersökningar af Ledningens Natur i den hvita Nervsubstansen. Akademisk Afhandling af Gustaf Fr. Göthlin. Uppsala: Almqvist & Wiksells Boktryckeri A. B., 1907. Pp. 406.

Beiträge zur Entstehung der Geschwülste. Dritte Ergänzung zur "Geschwulstlehre für Aerzte und Studierende." Von Hugo Ribbert, ordentlicher Professor der allgemeinen Pathologie und pathologischen Anatomie, Direktor des pathologischen Institutes in Bonn. Mit 19 Abbildungen. Sechs beginnende Karzinoome der Gesichtshaut eines Mannes. Bonn: Friedrich Cohen, 1908. Pp. 31.

Zur Differentialdiagnose der Poliomyelitis anterior acuta (Myotonia congenita (Oppenheim) und Polynucleuritis). Inaugural-Dissertation zur Erlangung der Doktorwürde an der Friedrich-Wilhelms-Universität zu Berlin. Von J. Victor Haberman, A. B., M. D., ehemals vol. Assistent an dem Eppendorfer Krankenhaus zu Hamburg und an der königlichen Charité zu Berlin. Berlin: S. Karger, 1908. Pp. 48.

Der Tod aus Altersschwäche. Von Dr. Hugo Ribbert, ordentlicher Professor der allgemeinen Pathologie und pathologischen Anatomie, Direktor des pathologischen Institutes der Universität Bonn. Bonn: Friedrich Cohen, 1908. Pp. 85.

Medizinisches Literatur-u. Schriftsteller-Vademecum, 1907-1908. Herausgeber: H. Albert, Bibliograph. Hamburg: Franke & Scheibe, 1908. Pp. 648.

Thirty-second Annual Report of the Managers and Officers of the New Jersey State Hospital at Morris Plains. For the Year Ending October 31, 1907.

Report of the State Board of Managers of Reformatories. Thirty-second Annual Report of the New York State Reformatory at Elmira, and the Seventh Annual Report of the Eastern New York Reformatory at Naperville. For the Fiscal Year Ending September 30, 1907.

The Harvey Lectures. Delivered under the Auspices of the Harvey Society of New York 1906-7. By Prof. A. E. Wright, Professor C. A. Herter, Professor W. T. Porter, Professor J. G. Adams, Dr. S. J. Meltzer, Pro-

fessor F. G. Benedict, Professor E. B. Wilson, Professor George S. Huntington, Professor W. T. Councilman, and Professor Friedrich Müller. Philadelphia and London: J. B. Lippincott, 1908. Pp. 314.

The Sanitation of Recreation Camps and Parks. By Dr. Harvey B. Bashore, Medical Inspector for the Pennsylvania Department of Health. First Edition. First Thousand. New York: John Wiley & Sons. London: Chapman & Hall, 1908. Pp. xi-109.

State Board Questions and Answers. By R. Max Goeppe, M. D., Professor of Clinical Medicine at the Philadelphia Polyclinic; Assistant Visiting Physician to the Philadelphia General Hospital. Philadelphia and London: W. B. Saunders Company, 1908. Pp. 684. (Price, \$4.)

Adenomyoma of the Uterus. By Thomas Stephen Cullen, Associate Professor of Gynecology in the Johns Hopkins University, Associate in Gynecology in the Johns Hopkins Hospital. Illustrated by Hermann Becker and August Horn. Philadelphia and London: W. B. Saunders Company, 1908. Pp. 270. (Price, \$5.)

### Official News.

#### Public Health and Marine Hospital Service Health Reports:

The following cases of smallpox, yellow fever, cholera, and plague have been reported to the surgeon general, United States Public Health and Marine Hospital Service, during the week ending May 29, 1908:

## Army Intelligence:

Official list of changes in the stations and duties of officers of the medical corps of the United States Army for the week ending May 16, 1908:

- CHAMBERLAIN, W. P., Captain. Granted an extension of twenty days to his leave of absence.
- CHURCH, J. R., Captain. Granted leave of absence for one month, about June 1st.
- GRUBBS, R. B., Captain. Ordered to Fort McIntosh, Tex., for duty, at the expiration of his present leave of absence.
- HARVEY, P. F., Colonel. Detailed to represent the Medical Department of the United States Army at the meeting of the American Medical Association, Chicago, Ill., June 2d to 5th.
- MUNSON, E. L., Major. Detailed to represent the Medical Department of the United States Army at the meeting of the American Medical Association, Chicago, Ill., June 2d to 5th.
- POWELL, W. A., Captain. Relieved from duty at Jefferson Banks, Mo., in time to sail July 5th from San Francisco, Cal., for the Philippine service.
- RAYMOND, T. U., Major. Ordered to perform the duties of chief surgeon, Department of Colorado, during the absence on leave of Lieutenant L. A. LaGarde, in addition to duty as surgeon, Fort Logan, Col.
- RUSSELL, F. F., Captain. Ordered to London, England, for a course of study in the British Army Medical School on the treatment of typhoid fever.
- SILER, J. F., Captain. Relieved from duty at Fort Des Moines, Ia., and ordered to Fort Slocum, N. Y., for duty.
- VOSE, W. E., Captain. When relieved from duty at Fort Slocum, N. Y., ordered to Fort Des Moines, Ia., for duty.

The following officers of the medical corps are detailed as chief surgeons at the respective manœuvre camps:

- Chief Surgeon, Department of California, at Atascadero Ranch, Cal.
- Chief Surgeon, Department of Colorado, at American Lake, Wash.
- Chief Surgeon, Department of East, at Pine Camp, Jefferson County, N. Y.
- Chief Surgeon, Department of Gulf, at Chickamauga Park, Ga.
- Chief Surgeon, Department of Lakes, at Fort Benjamin Harrison, Ind.
- Lieutenant Colonel J. M. Banister, at Fort Riley, Kan.
- Lieutenant Colonel A. H. Appel, at Fort D. A. Russell, Wyo.
- Chief Surgeon, Department of Texas, at Leon Springs, Tex.

The following officers of the medical corps are ordered to accompany troops from their respective posts to duty at the manœuvre camp, Pine Camp, Jefferson County, N. Y., June 15 to July 15, 1908:

- KENDALL, W. P., Major. Fort Ethan Allen, Vt.
- PEED, G. P., Captain. Fort Ontario, N. Y.
- PIERSON, R. H., Captain. Fort Niagara, N. Y.
- WEEF, F. W., Captain. Plattsburg, N. Y.

## Navy Intelligence:

Official list of changes in the stations and duties of officers of the medical corps of the United States Navy for the week ending May 30, 1908:

- CASTO, D. H., Assistant Surgeon. Detached from the *Maine* and ordered to the naval station, Guam, L. I.
- CATHER, D. C., Passed Assistant Surgeon. Commissioned a passed assistant surgeon on July 9, 1907.
- HOLEMAN, C. J., Assistant Surgeon. Detached from the naval training station, San Francisco, Cal., and ordered to the *Charleston*.
- LANE, H. H., Assistant Surgeon. Appointed an assistant surgeon from May 5, 1908.
- McMURDO, H. B., Acting Assistant Surgeon. Ordered to the naval training station at San Francisco, Cal.
- MAYERS, G. M., Passed Assistant Surgeon. Ordered to continue treatment at the Naval Hospital, Mare Island, Cal.
- MUNGER, C. B., Assistant Surgeon. Detached from the *Supply* and ordered to the *Maine*.
- OLD, E. H. H., Assistant Surgeon. Detached from the Naval Hospital, Canacao, P. I., and ordered to Washington, D. C.
- REED, E. M., Assistant Surgeon. Detached from the *Charleston* and ordered to the navy yard, Mare Island, Cal.
- WARNER, R. A., Passed Assistant Surgeon. Commissioned a passed assistant surgeon from May 3, 1908.

## Births, Marriages, and Deaths.

## Born.

CRUMP.—In Pittsfield, Massachusetts, on Tuesday, May 12th, to Dr. Irving Crump and Mrs. Crump, a son.

## Married.

BOTTOMLEY—KENNEY.—In Boston, on Wednesday, June 3d, Dr. John Taylor Bottomley and Miss Mary Agnes Kenney.

EMERSON—SKILTON.—In Boston, on Wednesday, May 27th, Dr. William Robie Patten Emerson and Miss Edna Skilton.

KANAR—RYDER.—In Albany, New York, on Tuesday, May 19th, Dr. William P. Kanar and Miss Margaret Edythe Ryder.

TOWNSEND—ADEE.—In Westchester County, New York, on Wednesday, June 3d, Dr. Raynham Townsend and Miss Julia Stanton Adee.

## Died.

ARCHIBALD.—In Slaughtersville, Webster County, Kentucky, on Monday, May 25th, Dr. L. A. Archibald.

BELL.—In Hampton, Virginia, on Sunday, May 17th, Dr. William S. Bell, aged eighty-four years.

COREY.—In Fredonia, New York, on Monday, May 25th, Dr. M. S. Corey, aged eighty-one years.

DAVIS.—In West Edmeston, New York, on Tuesday, May 26th, Dr. A. C. Davis.

DAVIS.—In Chicago, on Tuesday, May 19th, Dr. Wilson H. Davis, aged sixty-five years.

GALVIN.—In Louisville, Kentucky, on Monday, May 25th, Dr. Robert Emmett Galvin, aged forty-one years.

HAZARD.—In Cincinnati, on Sunday, May 24th, Dr. James Henry Hazard, aged sixty-two years.

HOPKINS.—In Brooklyn, on Saturday, May 23d, Dr. George Gallagher Hopkins, aged sixty-five years.

HORTON.—In Hammondsport, New York, on Sunday, May 24th, Dr. John T. Horton, aged fifty-one years.

HYLAND.—In New Amsterdam, New York, on Tuesday, May 26th, Dr. Thomas G. Hyland, aged fifty-one years.

LYON.—In Wheaton, Illinois, on Sunday, May 24th, Dr. Ellen Hancock Lyon, wife of Dr. H. N. Lyon.

McGINLEY.—In Chicago, on Tuesday, May 19th, Dr. James B. McGinley, aged forty-eight years.

PETTIS.—In Detroit, Michigan, on Friday, May 22d, Dr. A. J. Pettis, aged thirty-eight years.

RAYNER.—In Philadelphia, on Thursday, May 21st, Dr. Thomas Buckley Rayner, aged seventy-four years.

TROWBRIDGE.—In Buffalo, New York, on Wednesday, May 20th, Dr. Grosvenor R. Trowbridge, aged forty-five years.

#### HYGIENE AND MANAGEMENT OF PREGNANCY.\*

By AUSTIN FLINT, JR., M. D.,  
New York.

That part of the subject which has been assigned me by the president is a large one, if considered in detail. I shall therefore take it up in a general way from the standpoint of the general practitioner and try to emphasize those points which, in my experience, are often neglected.

In recent years many important advances have been made in the management of pregnancy which are far reaching in their results, for the welfare of both mother and child. It is not too much to say that most of the complications of labor and the puerperium can be forestalled and the dangers materially lessened by proper prophylaxis.

The first point to impress on physicians generally and on patients is the wisdom of assuming charge of the patient as soon as the diagnosis of pregnancy is made. Too often the patient postpones the employment of a physician until pregnancy is well advanced.

It will be more convenient to consider the management by dividing pregnancy into three periods of three months each. The first period comprises the time from the beginning of pregnancy until the end of the third month. I am accustomed to explain to patients that during this time it is necessary to observe the ordinary rules of health. The changes in the maternal organism are so manifold and the dividing line between health and disease is so ill defined that derangements, which in the non-pregnant condition are unimportant, may in the pregnant state give rise to pathological conditions which seriously affect the health of the mother and child.

Under ordinary circumstances a patient may be allowed to lead her usual life without restriction. She should be encouraged to take exercise in the open air, limited to walking; eat regularly, but only of plain food, and keep regular and early hours. As a rule, a pelvic examination is not necessary during this period.

Vomiting is the only symptom which needs careful investigation. When slight and limited to the morning, no treatment is necessary beyond some care in diet and perhaps some of the simple tonics. When vomiting is marked and persistent, an at-

tempt should always be made to discover its origin. A convenient working rule is to recognize three distinct types, neurotic, reflex, and toxæmic.

The neurotic is the most frequent and ordinary type, and may be distinguished by the exclusion of reflex irritation and toxæmia. It ordinarily begins at about the sixth week and continues until the beginning of the fourth month. Regulation of diet and removal of constipation, with the administration of five grain doses of cerium oxalate, will ordinarily improve the condition. In some cases pepsin, bismuth, or small doses of cocaine will produce excellent results. If vomiting is persistent, a pelvic examination and an examination of the urine should always be made.

The reflex type of vomiting is due to some pathological condition of the pelvic organs, a backward displacement of the uterus being the most common. Corrections of this condition and holding the uterus up by a suitable pessary is followed by a prompt cure. I am one of those who believes in the good effects of dilatation of the cervix, originally recommended by Copeman, although it is said that the good effects are often due to suggestion. The results of local treatment in cases where there is erosion and laceration of the cervix are often most satisfactory. Ovarian cysts demand removal, and an early operation should be advised.

If no pathological condition can be found on examination the case probably belongs to the toxæmic type.

**Toxæmic Type.**—Here the condition is properly called pernicious vomiting. It must be recognized that pernicious vomiting often begins as an ordinary neurotic or hysterical vomiting, and the patient may become toxæmic secondarily.

The recent work of Stone, Ewing, and Whitridge Williams has marked the most important advances in our knowledge of the management of pregnancy. Until then we knew very little about the pathology of pregnancy and what pernicious vomiting really meant. The diagnosis is made by the results of a chemical examination of a twenty-four hour specimen of urine. The presence of albumin and casts is significant of renal irritation only. In toxæmia of pregnancy, there is a profound disturbance of metabolism, indicated by a diminution of the total nitrogen and a relative increase of ammonia nitrogen. Williams has shown that the "ammonia coefficient" in the last half of pregnancy varies between four and five per cent., but in toxæmic vomiting it rises to ten, twenty, or even thirty per cent.

As soon as the diagnosis of toxæmic vomiting is

\*Read before the Medical Society of the County of New York at a conference on Obstetric Prophylaxis.

made the uterus should be emptied. In hyperemesis it is better to interfere too early than too late. The indication is based as much on the clinical picture as on the urinary findings. I have long taught that when vomiting is accompanied by weekly loss of weight, progressive exhaustion, and failure of the usual medicinal measures no time should be lost in emptying the uterus.

The change in the nitrogen distribution in the urine is an absolute indication for early abortion. The operation should be followed by copious enemas of saline solution, and little if any food given by mouth. Gastric lavage sometimes gives great relief.

In the second period of pregnancy I consider regular systematic examination of the urine as the most important part of the management. This should be done every second week up to the last month, when the interval should be every week.

The danger of the occurrence of eclampsia increases as pregnancy advances, and the only way that we can be forewarned of danger is to insist upon regular examinations. It is not necessary to go into details of management under abnormal conditions.

**Diet.**—During this period a full diet may be allowed, interdicting only wines and the more indigestible and richly flavored articles of food.

The patient should be instructed in regard to the value of beginning regular walking exercise, so that it can be continued without fatigue during the next period.

**Third Period.**—This is the time when prophylaxis is productive of best results. The points to be considered are: 1, Pelvic mensuration; 2, physical examination; 3, diet; 4, exercise; 5, care of the breasts; 6, examination of the urine.

**First.**—Pelvic examination is now the routine, almost as much in private practice as in hospitals. It is the only way that a diagnosis of pelvic contraction can be made. When we remember that contraction occurs in from twelve to fourteen per cent. of all cases the importance of careful measurements can be appreciated.

About six weeks before the date of confinement the patient should be instructed to stay in bed, and a physical examination, including the pelvic measurements, should be made.

I have found that there is seldom any objection on the part of the patient when its importance is explained. In cases where the pelvic measurements are small, six weeks allows ample time for interference.

A diagnosis of position and presentation can easily be made at this time and confirmed by subsequent examinations made from time to time, up to the beginning of labor. The size of the uterus, quantity of amniotic fluid, and the size of the child should be estimated. In primipara especially, and in all cases where the child seems large, good results follow a restriction of diet. In ordinary cases the restriction need be merely general, the patient being cautioned not to overeat. When real dystocia is feared the diet may be cut down to the smallest possible quantity in twenty-four hours. As pregnancy advances the relative size of the head

and the pelvic brim should be tested from time to time by trying to push the head down by external pressure. (Muller's test.)

For many years occasional mention has been made in obstetric literature in regard to the value of regulating the diet in pregnant women, with the object of preventing the overgrowth or full development of the child, and so preventing difficult labor.

This regulation was formerly limited to a reduction of the proteids, and I have unquestionably obtained good results by this method. A year or two ago my attention was brought to the results of the more scientific regulation of the diet, as recommended by Prochownik. Recognizing the high mortality in premature children when labor was induced for pelvic contraction, Prochownik applied the principles of dieting, which he had previously used for reduction of weight in adults, for the purpose of reducing the weight of children born at term. This procedure was employed as a substitute for the induction of premature labor in cases of moderate pelvic contraction. The results were favorable in all instances.

In cases of moderate pelvic contraction, or when dystocia from other causes is anticipated, Prochownik's diet should have a wider use. Contrary to previous ideas, this diet eliminates as far as possible all fluids and carbohydrates, allowing proteids and green vegetables, but these only in limited amounts. Then to fourteen ounces of fluids during the twenty-four hours was the original allowance. This is a diet which I have never strictly carried out, but have often approximated in cases where I have feared a difficult delivery. I can speak well of its value in preventing oversized children, and so far have never seen any ill effects. I have always been extremely careful to watch the urine closely, and increase the fluids whenever there seemed to be any kidney irritation. I have occasionally found a trace of albumin in the urine, but it has always been transitory, and disappeared after a temporary increase in the amount of fluids taken by mouth.

The general health of patients should be carefully supervised. An abundance of fresh air and walking exercise is of the greatest value. Beginning with a walk of at least half a mile during the middle third of pregnancy, the daily walks should be increased to two miles during the last two months, and this can usually be accomplished without fatigue. Nothing will favor preliminary softening of the lower uterine segment and allow the head to sink down through the pelvic brim as well as these daily walks. It is not unusual to find the head in the excavation of the pelvis and the cervix soft and partially dilated a week or ten days before the onset of labor, even in primipara.

During the last third of pregnancy the patient should be instructed in regard to proper clothing. An abdominal binder or corset should be worn, so as to hold the uterus up, and hold the long axis of the child in the axis of the pelvic inlet.

The corset or abdominal supporter not only contributes materially to the woman's comfort, but its use is almost necessary during the time of exercise

if we wish to produce a preliminary softening of the lower uterine segment. In cases in which this softening is marked a short first stage may confidently be expected.

A factor in labor which can never be definitely prognosticated is the quality of the labor pains. In a vigorous woman, with good muscular development and in good health, nothing need be done in the nature of trying to improve the strength of uterine contractions. On the other hand, if the health is below par, if the patient says that she tires easily and cannot walk as far as she should, and especially if the pulse is weak, moderate doses of strychnine, with small doses of quinine, should be given regularly three times a day for the last six or eight weeks. This plan has been used by many observers with results that seem variable. There is no doubt that, in suitable cases, it is a most valuable aid. I have made use of it in a number of multipara, with histories of prolonged labor, and have invariably found that it caused stronger pains, a shorter labor, and guarded against the danger of postpartum hemorrhage, or a relaxed flabby uterus after the birth of the child.

Care of the Breasts.—At the time when the regular physical examination is made the condition of the breasts and nipples should always be ascertained.

The old saying that "every healthy woman should nurse her own child" is as true now as it was years ago. When no attention is paid to the preparation of the nipples nursing is an ordeal which is justly dreaded by a woman about to become a mother. When properly prepared for, nursing should not only be painless, but usually proves to be a source of intense satisfaction to all concerned.

Beginning about six weeks before the calculated date of confinement, the nipples should be painted over with a solution of tannic acid in glycerin every night and at the same time be manipulated and drawn out for a few minutes at a time. It is said that manipulation of the nipples may cause premature uterine contractions, but I have not seen this in any of my cases. The patient should be instructed to so arrange the clothing that the nipples are not pressed upon. The recommendation that the nipples should be bathed occasionally in some astringent, such as alcohol or bay rum, is also of value.

Examination of the Urine.—It is especially important that regular examination of the urine should be made. This should be done at least once a week for the last six weeks, in order to be forewarned as much as possible in regard to the ever increasing danger of eclampsia.

A physician does not perform his duty to his patient who does not make it a rule to personally see her at frequent intervals during the entire period of pregnancy. It is impossible to treat the pregnant condition in any other way.

Every one who has had even a moderate obstetrical experience knows that a large number of cases which were formerly regarded as physiological really are pathological. As an example, it is only necessary to remember that toxæmia is now known to be the cause of the vomiting in many

cases which were formerly regarded as physiological "vomiting of pregnancy."

As an illustration that a woman may suddenly, with hardly any warning, develop a serious condition in pregnancy, the following unusual case is briefly reported:

CASE.—K. M. was admitted to Bellevue Hospital on April 28, 1905. She was a primipara at term and apparently in her usual health and had had no previous illness. Two days after admission, she complained of slight pains in the abdomen, but it was considered to be of trifling moment. She was given free catharsis and felt considerably better. May 3d (three days later), she again began to complain of pain in the abdomen and back, and in addition vomited after meals. She was put to bed on a milk diet and a twenty-four hour specimen of urine examined with negative results. She then developed headache, slight vertigo, vomiting, and pain in abdomen, which continued until May 9th, when she was transferred to my service at the Emergency Hospital. The urine on examination on May 7th showed a faint trace of albumin, specific gravity 1.013, total quantity thirty-eight ounces, and urea 4.5 grains to the ounce; no casts. Pulse was 80, regular, of good quality and normal tension. On the day she was transferred, it was noticed for the first time that she was slightly jaundiced. Physical examination was negative, excepting that "liver percussion showed dullness in sixth space, and dull tympany to free border of ribs; edge not felt," whereas on admission it was noted as "dull in fourth space, flat in fifth space." This showed a distinct diminution in the size of the liver, which was significant of a possible acute yellow atrophy.

She was put under chloroform and the cervix dilated. In the afternoon, although there were moderately strong pains, she did not progress rapidly, and in the evening the cervix was again manually dilated, followed by immediate version and delivery of a female child. After delivery, the general condition was good, but she did not sleep, and four hours later vomited some dark brown material. On May 10th (the next day), condition was fair, she complained of headache through the day; was given a calomel series and saline irrigations of colon. On the 11th, vomiting continued. In the afternoon phlebotomy was performed, and six ounces of blood withdrawn, followed by a saline infusion of 1,200 c.c., which improved her condition markedly. She slept quietly, pulse 96, regular, full, of good force and size. During the evening she had a sudden attack of syncope and became pulseless, with shallow and rapid respiration. She was given oxygen, stimulation, etc. *No cyanosis.* Colon was again irrigated with six gallons of saline and she improved slightly. She was conscious and rational, but the jaundice deepened rapidly. During the night she had muscular twitching of the face and extremities, and early in the morning became mildly delirious, and complained incessantly of thirst and pain in the abdomen. Her condition became gradually weaker during the day; pupils contracted and pulse almost imperceptible. The jaundice became more marked and there was a distinct uræmic odor. She died about 3 p.m.

The diagnosis of acute yellow atrophy of the liver was confirmed by a careful autopsy by Dr. Norris, the report of which is too long to be quoted.

The urine examinations on May 10th were characteristic. Amount 1,000 c.c., specific gravity 1.010; highly colored, with a heavy sediment of mucus and epithelial cells. The total nitrogen was 7.25 grammes, ammonia nitrogen 0.725 gramme; urea, 4.32 grammes; and uric acid, 0.52 gramme. "Considerable leucocytes and bacteria, which form a large part of the rest of the nitrogen."

This case was studied by Dr. Lwing and Dr. Beebe, and the pathological findings incorporated in papers by them, but so far has not been reported clinically.

The lesson it teaches, namely, the necessity of careful urinary and physical examinations in all cases of pregnancy, is obvious.

## SUPRAPUBIC PROSTATECTOMY IN TWO STAGES.

BY HOWARD LILIENTHAL, M. D.,  
New York,

Attending Surgeon to the Mount Sinai Hospital.

The operation described in the title has given me such a sense of security in dealing radically with so called bad operative risks that I wish to describe the method in detail and to illustrate its enormous advantages with the aid of a few histories. No matter how feeble the patient, or how desperate the emergency, one may feel sure that by operating in two stages by the suprapubic route our patient is incurring the absolute minimum of hazard.

As in the modern teaching of mathematics the student is made to deduce the rule after having worked out the problem, so it may be instructive here to recount some typical histories and to deduce from them the principles which shall govern us in the treatment of similar cases.

CASE I.—J. M., fifty-nine years old, had been suffering for many years with symptoms of prostatic obstruction. There were periods of acute prostatism during which the frequent use of the catheter was necessary, but for months at a time he would worry along with occasional catheterization and urination by overflow. Finally he set the day for operation, but twenty-four hours before the time appointed a rather severe bleeding began. His physician tried every means at his command to relieve him, but acute hæmorrhage resulting in prostration with great pallor and small pulse threatened his life, and operation with incomplete preparation had to be performed.

Under light chloroform narcosis a suprapubic cystotomy easily emptied the distended bladder of its contents—urine and a large quantity of blood clot. In Trendelenburg's posture, a bleeding vessel at the most prominent part of an enlarged middle lobe was easily seen and touched with the actual cautery. A few gauze packings and tube siphonage completed the procedure. There was no more bleeding. The patient soon recovered from the shock of the rapid depletion, and in four days was once more lightly anesthetized, and the prostate enucleated through the original wound.

The man had been told that the second anæsthesia was for the purpose of removing the gauze packings from his bladder, and not until he was well on toward recovery did he learn that the operation had not been completed at the first sitting.

It seems probable that prostatectomy at the time of the first operation during the shock of the recent hæmorrhage would have proved fatal.

CASE II.—W. S., sixty-three years old, had for two years complained of symptoms of obstruction due to enlarged prostate. The urine had been cleared by urotropin and there was no history of hæmorrhage. Several attacks of retention. Suprapubic cystotomy under local anæsthesia was followed by the usual relief which drainage of the bladder affords, the patient being out of bed on the second day and walking about after the third day. One week later, in chloroform anæsthesia, the prostate was enucleated. Hæmorrhage was very slight. Packings and tube as usual. The patient sat up out of bed the next day, and in three days was permitted to walk a little. The urine did not become clear of blood, however, a considerable oozing gradually going on, so that at the end of another week he had become quite anæmic and had to go to bed again. Astringent washes and efforts to secure hæmostasis by the more usual means were unsuccessful, so two weeks after the prostatectomy it was necessary to anesthetize once more, elevate the pelvis of the patient and look into the bladder. The picture was an extremely interesting one. The prostatic wound seemed to have completely healed, a deep and wide sulcus having taken the place of the bulging organ at the base of the bladder. The bleeding came from an arteriole in the mucous membrane of the right side of

the bladder, close to the depression where the prostate had been. This arteriole was not in a part of the mucosa which had been wounded during operation, but lay in an otherwise healthy fold at least an inch to the right. It is possible that the tube had caused the abrasion. The point was touched with the Paquelin. Hæmorrhage was instantly checked, and the patient was sent to bed without any intravesical packing, and with the tube so short that it barely entered the suprapubic wound in the bladder. Recovery was now rapid and uneventful.

The beautiful and perfect exposure with the suprapubic incision, aided by Trendelenburg's posture, made it possible to save this man's life.

CASE III.—I was called to see Isaac W., seventy-five years old, his bladder distended to his umbilicus, his pulse hard, tongue dry, and his arteries degenerated. He was cyanotic, and his sensorium was clouded. Catheterization was difficult, and the surroundings of the patient were such that instead of emptying the bladder and then partly filling it with salt solution, I adopted the more ancient custom of leaving one half the urine within the viscus, advising an immediate removal to the hospital for operation.

This man's condition was truly alarming, and confidence in his resisting power was still further lessened by his gaunt and hollow eyed appearance. On arrival at the hospital he was stimulated with strophanthus and judiciously catheterized until the next day, when cystotomy, under local anæsthesia, was performed. Hæmorrhage was practically absent. No vessel had to be tied. After even this slight operation his condition became so critical that for several days his death might have been hourly expected. Gradually, however, he improved, and by the end of the second week he was out of bed and on his feet. I attribute much of his weakness to the fact that he had been bedridden for two weeks before he came under my observation, a serious error in the treatment of this disease in the aged.

After the expiration of two weeks the second stage of prostatectomy was performed under short general anæsthesia. Forty-eight hours afterward he was out of bed and made an uninterrupted though rather slow recovery, the wound being entirely healed in four weeks from the time of the second operation.

Had this man succumbed after the first operation, the cystotomy, the prostate not having been touched, it seems reasonably certain that his death would all the more have been inevitable had the entire operation been performed at one time. Death after the first operation could certainly not have been ascribed to suprapubic prostatectomy.

It is hardly necessary to multiply histories of this kind. They are so similar that little is to be learned from the repetition, except that each succeeding case may be approached with greater and greater confidence. The patient is taking his risk in instalments, as it were, and, instead of being put once in great jeopardy, he has been put twice in comparatively little danger.

The advantages of the operation may be summed up about as follows:

1. The dangers of serious hæmorrhage are minimized, both on account of the lapse of time between the two stages, and also because the functional rest of the bladder after cystotomy greatly reduces the congestion of the mucous membrane.

2. The total time of operation, including both stages, is considerably shortened, the time of general anæsthesia being reduced not one half, but probably three quarters. The combined time of the actual operative procedures is rarely more than seven minutes and often less than five. Shock, which is a combination of the effects of hæmorrhage and length of operation, is therefore greatly reduced. Patients who succumb after the cystotomy would almost certainly have died following cystotomy plus prostatec-

tomy; in fact, a death following cystotomy could not be ascribed to prostatectomy in two stages.

3. The exploration of the bladder by sight and touch at the time of the cystotomy is most perfect, and the surgeon has time between operations to lay out his plan of attack and to get his patient in excellent physical condition. The suprapubic incision and the Trendelenburg posture permit of the most careful scrutiny of every part of the interior of the bladder, and the operator is given an opportunity of observing from within the actual conditions and causes of the obstruction. Preliminary cystoscopy is not only unnecessary, but extremely ill advised, for cystoscopy in the class of individuals under discussion is by no means without danger. To show how unnecessary and even misleading cystoscopy may be in these cases I present:

CASE IV.—A. W., aged seventy-six, had hæmaturia and dysuria for a number of months. Cystoscopy by another surgeon demonstrated rather doubtfully the presence of an enlarged prostate, the left lobe being principally involved. I planned a two stage prostatectomy, but at the preliminary cystotomy an isolated, ulcerated tumor of the vesical wall was clearly demonstrated and was recognized as a malignant growth. The tumor was the size of a silver quarter and occupied a position in the left lower part of the bladder, above and anterior to the urethral opening.

I made a wide excision of the tumor through all the coats of the viscus, reuniting the bladder walls with sutures of catgut within and silk without. The suprapubic wound was permitted to drain. The prostate was not enlarged.

The histological report by Dr. Mandelbaum, pathologist to the hospital, was "squamous celled carcinoma."

The patient made a good recovery, dying of a relapse about a year and a half later. This relapse did not show itself for more than a year, during which the patient remained well.

It will be noted that cystoscopy, though performed by a competent man, was of little value, while cystotomy, the pelvis of the patient being well elevated and the interior of the viscus exposed with blunt retractors, left no room for error.

4. Preexisting cystitis is cured by drainage and urinary antiseptics before the prostatectomy proper. Days or weeks may be required, but we shall have gained two important factors of safety, a comparatively aseptic field and a comparatively healthy man. The hæmorrhagic cystitis following the sudden relief of an over distended bladder has also usually disappeared by the time we are ready for our second step.

5. Relief of back pressure on the kidneys with readjustment to normal conditions before prostatectomy.

6. When the operation is performed at one sitting there is necessarily a considerable pushing away of the bladder from the abdominal wall, sometimes opening up the space of Retzius. This is unnecessary if a simple cystotomy is performed, and at the end of five or six days firm adhesions have taken place, sealing the space and avoiding infection.

7. Injury to the rectum is practically unknown. I have never caused such injury in performing suprapubic enucleation of the prostate, nor do I know of any surgeon who has been unfortunate enough to meet with this accident. It is comparatively common in the perineal operation.

8. The power of performing the sexual act is rarely interfered with in suprapubic operations upon the prostate, while it is often lost after even slight operations in the perineum. I have several cases in which sexual—not reproductive—power has even been increased after the operation.

One disadvantage of suprapubic prostatectomy, whether in one or two stages, is that, although it is an extremely safe operation, the convalescence is apt to be rather slow, the patients usually remaining in the hospital about four weeks.

I have never seen a permanent suprapubic fistula after this method of prostatectomy. One case, however, gave me considerable trouble.

CASE V.—T. A., sixty years old, had been operated upon some years before by a surgeon who had performed a suprapubic cystotomy by a transverse incision, severing a considerable portion of the recti. At this time the prostate, though enlarged, was merely cauterized. The fistula closed very slowly. Temporary relief was followed by a return of his prostatism with almost complete retention and considerable cystitis.

I operated by a median sagittal incision, removing the prostate in the usual way. The fistula at the crossing of the two cicatrices did not close for several months, but eventually there was final and complete recovery.

#### *Description of the Method.*

If the case is not an urgent one, two days of preparation are advisable. In addition to the usual catharsis and general preparation it is well to give ten minims of tincture of strophanthus every six hours and ten grains of salol three times a day. If catheterization is easy the bladder should be completely emptied every three hours, day and night, for the two days. The patient's bladder is emptied on the operating table and the catheter left in place.

Under local anæsthesia a median incision of from two to three inches through the skin and aponeurosis is made, the recti are retracted and the bladder distended with air through the catheter by means of an ordinary atomizer bulb worked by an assistant. The finger of the operator detects with ease the tense, elastic wall of the bladder, and with a blunt instrument or with the finger the reflection of the peritonæum is easily stripped upward and held there by a blunt retractor. There is little, if any, likelihood of dangerous pneumatic pressure, first, because the patient will give the alarm, and, second, because the air leaks out in considerable quantity alongside of the catheter, so that from time to time the pumping up will have to be repeated. With a sharply curved needle with silk, the entire thickness of the bladder is caught in a temporary traction suture, first on one side and then on the other. A short sagittal incision between these two ligatures, held taut by an assistant, opens the viscus and permits of digital exploration. This opening may then be stretched with the fingers and the patient placed in Trendelenburg's posture. Retraction completely exposes the interior. The catheter at once indicates the location of the internal urethral opening. The time consumed, without the slightest haste, will not be more than two or three minutes, and I have frequently entered the bladder by this method in one minute *without hurrying*. The operation is extremely easy. Usually no blood vessels require ligation.

After the exploration and the removal of calculi if any are present, a rather large drainage tube is inserted, the silk traction ligatures are left in place,

I use the word "drainage" instead of "prostatectomy" because I believe that the recurrence of the tumor is more common at its original site than after its removal. I have seen several cases in which I would suggest that this distinction should be made in the report.

the space of Retzius is walled off by packings, a snug bandage is applied, and the patient is sent back to bed. The next day he should be made to sit up in a chair. If much cystitis is present the bladder should be washed out through the tube two or three times a day. In four or five days urotropin or some similar formaldehyde preparation should be given instead of the salol; cardiac stimulants as needed. In three days the patient may be permitted to walk about, still securely bandaged. He will probably be wet and uncomfortable, but happy in his relief from the burden of the catheter.

In from five to ten days, rarely longer, the second step of the operation may be performed. Complete relaxing anæsthesia for five or six minutes is required. If the abdominal muscles of the patient are not relaxed the operation is difficult; if they are relaxed, it is easy. Trendelenburg's position is not essential. If the opening has become small by granulation it should be quickly stretched digitally. With a pair of blunt pointed scissors, in the most prominent part of the prostate, on the posterior lower wall of the bladder, over the middle lobe, if there is one, a rather deep incision is made. The finger of either hand searches for the planes of cleavage, and the tumor is shelled out. This is rather easily accomplished. The absence of distinct cleavage is suggestive of carcinoma. This part of the operation can best be performed with the ungloved finger. If one finger cannot do the work properly, use two; if one hand becomes tired, use the other. The assistant should raise the prostate through the rectum toward the operator. Considerable force may be necessary in detaching the prostatic tumor from its bed. When working near the deep urethra the exercise of a little care and the avoidance of undue haste will prevent injury to the urethra. In those cases in which the entire mass comes away in one piece, tunneled by the urethra, it will be seen on microscopical examination that the lining of the urethra has been drawn out of the opening in such a way that no mucosa will be found. If the diseased prostate consists of a number of adenomatous masses it may be necessary to remove them separately. One should be pretty sure to remove the greater part or as much as possible of the enlargement. At times it happens that the prostate is too large to be extracted through the suprapubic wound in one piece, although it may have been detached and lies loose within the bladder. It should then be divided and taken away in several pieces rather than to enlarge the vesical incision.

The bladder should now be flushed out with hot water and the prostatic portion packed with gauze *outside* the mucosa in such a way as to obliterate as far as possible the opening from which the prostate came. A considerable portion of the mucosa will at once become adherent to the walls of the depression, leaving only a small part to be filled in by granulations. This is much better than to pack the raw prostatic cavity, as was formerly practised. A few more packings of gauze, carefully distinguished for future identification from those which go to the prostatic region, are now placed in the bladder, and the patient sent to bed with a heavy sand pad over the lower abdomen. The next day the upper vesical

packings are taken out and a tube put in. In forty-eight hours the remaining packings may be removed.

During convalescence from the second stage of the operation the testicles should be well supported, but in a certain number of these patients epididymitis develops, and it seems to be impossible to avoid this complication. At the end of forty-eight hours the patient may sit up in bed, and in three days may be out of bed. The urine contains blood for several days after the operation. The first urine by the natural passages will probably be passed in from ten days to two weeks after the prostatectomy; occasionally, when the suprapubic wound was rather large, urination may not occur for a longer time. It should not be necessary to pass any instrument into the bladder by way of the urethra, but it is of great importance that the viscus be thoroughly flushed out twice a day through the wound for the first week after the prostatectomy.\*

115 EAST SEVENTY-THIRD STREET.

#### PRESENT DAY LIMITATIONS OF OUR CONCEPTION OF PARANOIA.\*

By M. S. GREGORY, M. D.,  
New York,

Resident Alienist, Bellevue Hospital.

In opening the discussion this evening I desire to present to you certain clinical view points which in my experience have helped me in this complicated question of the paranoid states. At the outset let it be understood that I make no pretense of trying to solve the paranoia problem. We all know that the origins of paranoid delusion formation are extremely complicated, and it is not my intention to attempt a complete psychological analysis, notwithstanding its great importance, and in spite of the fact that it is probably only through such complete psychic analyses that we may ultimately come to understand some of the more subtle distinctions in this field of psychiatry.

I shall not attempt a complete historical résumé of the paranoia problem, interesting and instructive though it may be, but shall consider only those later day conceptions which are still subjects of controversy.

Terms are often idle subjects of discussion, for, were we to confine our ideas of the term to its earliest application, we would find that in the original Hippocratic form the word *paranoia* was used both as synonymous with dementia and with the entire subject of insanity; just as, in the times of Pinel, works on psychiatry were called treatises on mania.

But it is not so much with the word *paranoia* that we would deal as it is with the later day conceptions of what groups of cases we are to place in this class, allowing for the gradual modifications which have come about in later interpretations.

The modern conceptions of paranoia, as I shall

\*Dr. Follen Cabot, professor of genitourinary surgery in the New York Postgraduate Hospital, and Dr. H. Goldenberg, genitourinary surgeon to Mount Sinai Hospital, have both assured me of their great satisfaction with this method and both of these gentlemen have been able to test its merits in comparison to those of other operations.

\*Read before the New York Neurological Society, May 5, 1908, in opening the discussion on the subject.

\*This advice would seem superfluous. It has, however, been found to be necessary.

speak of them, have clustered about the understanding of what English psychiatrists termed for many years partial insanities, or moral insanities, or monomanias; the French as partial or systematized delusions; and the Germans under the general term *Verrücktheit*, and *Wahnsinn*. Esquirol, as early as 1820, gave us the term monomania, but Laségue, in 1852, under the title *délire de persécution*, was perhaps the first to fairly set in motion the more detailed study of this general group of cases, which, culminating with the classical study of Magnan in 1882 (*Le Délire chronique à évolution systématique; générale et partielle*), received, so far as the French school is concerned, its final definite form. Arnaud's treatment of the group in Ballet's monumental treatise does not go beyond the conceptions of Magnan.

In Germany we can go as far back as 1818, when Heinroth utilized the term paranoia, but his psychiatry is so mingled with ecclesiastical metaphysics that it is impossible to pick out just what he did mean. Snell in 1865 and Griesinger in 1868, working along similar lines to the French observers, described the types of *Wahnsinn* and primary *Verrücktheit*, while Sanders in 1868 also described an original *Verrücktheit*, in which we see the general beginning of the crystallization of our present day idea of paranoiac form of dementia præcox and paranoia cases, out of the mass of delusional patients with relatively unimpaired intelligence. Krafft-Ebing in 1879 again took up the old Greek term paranoia, applying it to the systematized delusions in general and following Magnan closely, and was an adherent of the view that the disease existed only in a chronic form. Mendel, on the other hand, in 1893, assumed a more general position, and described acute and chronic paranoias, which, as I believe, is responsible for most of the confusion in our interpretations of what should be understood by paranoia.

Of the modern students of psychiatry, Cramer and Ziehen represent the same tendency, and, like Mendel, they regard the superficial symptom picture, instead of applying the severe clinical criteria, which have contributed to establish the ideas of Kraepelin on a much broader foundation. It is this same attitude, namely, the overvaluation of certain symptom groups, which regards depression as the equivalent of melancholia, excitement, as synonymous with mania, and therefore delusional formation and hallucinations are deemed sufficient to establish the group of paranoia. Thus, from this point of view, a narrow, symptomatic test, we have acute and chronic paranoias, paranoias with and without hallucinations, primary and secondary paranoias, curable and incurable paranoias, in all of which the chief criterion is the presence of ideas of influence, of ideas of observation, of ideas of persecution, etc., which become united into a delusional system, more or less consistent and stable, according to the type under observation. We thus have such diverse conditions as postalcoholic delusional states called acute paranoias, and if the alcoholic hallucinations persist, acute hallucinatory paranoias. A similar interpretation exists for posttyphoid delusional

states; for postinfluenzal toxæmias, and throughout the long list of toxic and infectious diseases, in which mental involvement appears, as it frequently does, as a disorder in the elaboration of ideas, leading to delusional interpretations of the surroundings.

Further, in the manic depressive group of insanities, particularly in the hypomanic phases, we may find at times a well marked delusional system, which is fairly stable. These are classed by the followers of Mendel and Ziehen as acute, or as periodic paranoias, and contribute to the class of paranoias which recover.

In the same category one must bear in mind cases of early paresis, of epileptic insanity, of hysterical insanity, of senile deterioration, etc., which may show a picture, at some time in their course, of delusional formation in which ideas of reference, of observation, of persecution, are the most striking features. Viewed from the narrow standpoint of symptom picture alone, these patients are classed, by the authors mentioned, as acute or chronic paranoias, whereas the fundamental and essential disorder is something quite different and the paranoid complex merely an episode.

On the other hand, we have seen the ideas of Kraepelin develop along an entirely different line. "The symptom picture of to-day," he says, "changes slightly to-morrow." Therefore delusions and hallucinations are not to be regarded as pathognomonic of any one mental disorder; no one symptom, or small group of symptoms, can be so regarded; and he insists on the full consideration of all the facts of the case; a true clinical summing up of the whole situation in terms of onset, course, and termination before we are in a position to satisfactorily classify our patients. Thus, at least ten years ago, at one bold stroke, he demolished the artificial barrier that was supposed to separate the so called intellectual disorders from those involving the emotions, and distributed the acute delusional and hallucinatory patients, with relatively intact intelligence, into more natural groups, as determined by ætiology, course, and outcome. Paranoia almost disappeared.

"Of what use to us," he says, "is the analysis of the whole group of disorders of intelligence, with its finest variations, if through it we cannot at the same time learn whether the patient will get well, whether he will be periodic, or simply demented, or whether he will become crazy in the old sense?" "Concerning these important matters we must come to definite diagnostic conclusions which satisfy us and clear our conceptions." "There is no doubt that no advance steps can be made if the universal disease paranoia, which, according to many alienists, includes seventy to eighty per cent. of all the insane, is regarded in this manner." "We know very well that delusion formation and hallucinations occur in the recoverable and irrecoverable cases, in the acute and in the chronic forms, in the simple and the periodic forms of insanity, and of themselves, offer no definite key to the prognosis of any single case."

Kraepelin's application of this idea reduced the paranoia group in the old sense, as he himself

states, from seventy to eighty per cent. of all insanities in asylums to about ten per cent.—which seem to have fundamental characteristics in common.

However, he even went further and excluded from this group those cases which terminated, in the great majority of patients, in a rapidly progressive dementia, and in whom hallucinations played a prominent part, thus reducing paranoia as described by him to less than one per cent. of the cases, found in hospitals for the insane.

Whether Kraepelin is justified or not in his grouping of the large bulk of these cases under dementia præcox future observation and experience alone will determine. It is very likely that it comprises several groups of closely allied disease processes which in the present state of our knowledge we are unable to distinguish.

Thus summing up the position assumed by Kraepelin, we are reduced to the consideration of two groups of cases, the one a comparatively large assemblage of so called secondary paranoias or paranoid forms of dementia præcox, showing the typical intellectual deterioration, the disorder of attention, and blunting of the emotional tone with more or less systematized delusional formation; and a still narrower and numerically smaller group in which the delusional formation is unaccompanied by the other attributes of intellectual impairment. So far as the acute cases are concerned we have seen that they can be excluded, for the most part, and apportioned to their fundamental groups as indicated.

It appears to me that this restricted group of paranoid forms, making up perhaps about ten per cent. of our cases, can be regarded to clinical advantage as some of the French writers, especially Magnan has done, but with slight modifications; not that it is any more scientific, but rather because it possesses certain clinical advantages. This class may be divided into two general groups with transition forms—first, those cases in which there is progressive mental deterioration and in which hallucinations play a prominent rôle, and, secondly, a nondeteriorating group in which hallucinations are not characteristic, and heredity plays a strong part.

Within this first group certain further forms stand out clinically, and I see certain subdivisions which are fairly clear, as follows: (a) Chronic delusional insanity as described by Magnan. This is a well known type, and by many alienists and writers is taken as a model for the description of paranoia in general, and other forms are given as slight modifications. It was first described in a masterly fashion by Magnan, who insisted that this form must not be confounded with apparently similar states and must not be taken as the representative of the whole group. He taught that in diagnosing this form, not only certain symptoms, but the whole clinical picture—its development, regular characteristic course, and termination—must be taken into consideration. He divided it into the well known stages of development, delusional formation, transformation of personality, and dementia. It is gradual in onset and slowly progressive. Hallucinations are always present at some stage of the disease, and play a fairly impor-

tant rôle. Into this type fall the kings, emperors, and prophets of the insane asylums who fantastically decorate themselves.

(b) A second group is closely allied to the former, but differs from it in that it shows many of the characteristic symptoms of dementia præcox. The onset is acute, the delusions are shifting, fantastic, and bizarre, and lack logical formation. Mental reduction soon supervenes, especially in the affective sphere. Transformation of personality, if it appears at all, comes on soon and at times very suddenly. In addition, many dementia præcox symptoms appear, such as mannerisms, negativism, stereotypy, etc. Hallucinations are commonly present, and play a strong part in the disease.

(c) A small group might be made of those cases in whom the delusional state is circumscribed and apparently wholly dependent upon hallucinations and somatic, false perceptions. I refer to a group of persons who apparently are able to go through life for many years occupying responsible positions without suffering any marked mental reduction. The delusional system is very limited; the patient apparently pays little or no attention to it, except episodically, when he is stimulated by the hallucinations and false perceptions.

A brief summary of the following case might be taken as illustration of this last group:

CASE I.—Miss R., forty years old; unmarried; from rather neurotic stock. One brother is said to be "nervous," probably insane. She is a refined and cultured woman and for the past fifteen years has been able to support herself without much outside assistance. For the past few years she has been a teacher in the public schools of this city, which calling she has followed with apparent success. About fifteen years ago she experienced strange sensations in her back and about her sexual organs, as well as in her abdomen. She describes these strange sensations as being similar to shocks of electricity passing through her body, especially up and down her "nerve trunk," as she terms it. This strange feeling would at times take the form of internal language or words. She at first supposed she was suffering from a physical disorder, but when she began to hear words and this internal language, she became somewhat apprehensive and consulting a specialist, endeavored to get an explanation. She states that she could get no satisfactory explanation from the professional man. At the same time her attention was attracted by her reading to spiritualism and other mystic influences. She at once decided to investigate these cults, hoping that they would perhaps throw some light on her trouble. She consulted spiritualists and others who concern themselves with occult matters. These authorities gave her a ready explanation of her condition, stating that spirits were having communion with her to some purpose and that her experience was not in any way out of the ordinary. It was also explained to her that perhaps evil spirits were working to carry out the designs of some persons who were unfriendly to her. After considerable thought she accepted this, as it seemed to satisfy her more than any other explanation she could find. At any rate, she formed the circumscribed and limited delusion that perhaps some one who was unfriendly to her for some reason, and who possessed power in this mysterious sphere, had been annoying her. She states, however, that although she was very much concerned and worried about the affair at first, she soon regarded it lightly and did not permit it to interfere with her daily routine life, except when these mysterious influences would become very marked, when it was impossible for her not to take notice of them. This state of affairs continued for from fifteen to eighteen years, during which, as has already been stated, she taught school and was able to get along without assistance. She is an intelligent, refined, cultured woman, a good conversationalist, and shows a good deal of ability and knowledge in discussing current topics, and unless she chooses to speak

about her delusional ideas she shows no symptoms of mental trouble, but impresses those with whom she comes in contact as of more than average intelligence. When she talks of her delusions in her endeavor to explain her experience, she becomes excited and almost incoherent. However, as soon as the subject is changed, she calms down and again becomes rational and reasonable. Her delusional system has not shown any tendency to spread, is limited and circumscribed, and has remained so for many years. Her false ideas appear very fantastic when regarded in a superficial way, but really, it is a plausible explanation when measured by the doctrine of the cult, which in itself is fantastic.

This class of patients may be regarded the same as those in the first group. Perhaps the general progress of the disease was checked in some unknown way, and this diseased condition remains intact without having spread further. The only reason for grouping these patients as a separate one is for clinical and therapeutic convenience.

2. The second large group comprises the so called nondeteriorating or degenerative insanities of the French writers. They differ from the former group in that they do not terminate in dementia, hallucinations are not present, and they invariably show marked hereditary taint. The subdivisions of this group are:

(a) Chronic progressive paranoia as described by Kraepelin, which comprises less than one per cent. of asylum cases, although represented in a much larger proportion in the general population. The salient features of this group given by him are that the delusional system is "enduring," "unshakable," and "increasingly progressive with complete retention of the order of thought process." The delusions are reasonable and logical, and are based in part on facts which are distorted and incompletely observed. No distinct hallucinations occur—at least I have never personally met with them in my experience. False perceptions and misinterpretations of the environment with retrospective memory disorder are the basis of the delusional concepts. After many years some slight mental weakness may supervene, but there is never any marked deterioration. Many are capable of carrying out business and professional undertakings with a certain degree of success. Many paranoiac reformers, litigants, platonic lovers, and regicides fall into this group.

(b) A second subgroup can be made of those individuals who have a psychopathic constitution and who under adverse conditions develop a paranoid complex. These persons are eccentric, one sided, unstable individuals, and might be termed potential paranoiacs. Occasionally they may be brilliant and talented in some one direction. A person of this type, after some disappointment or failure or after some occurrence which intensifies his natural tendencies and weaknesses, readily develops the paranoid complex in a typical psychogenetic manner, as has been so ably demonstrated by Dr. Meyer and Dr. Hoch.

Their system of delusions, however, unlike the preceding group, is not broad, progressive, and comprehensive, but is limited to a particular subject and its immediate ramifications. They readily misinterpret and misconstrue ordinary facts in the light of their delusions, but never show hallucinations. If any hallucinations are present they are

due to extraneous influences, such as alcohol or intercurrent disease, etc. The main deviations of this type, then, from those of the true paranoia group are such that the delusional system is limited and is the outgrowth of the patient's former tendencies, intensified by adverse conditions, which, when removed, permit of a symptomatic recovery. The following case is typical of this group:

CASE II.—Male, forty-one years of age; married; tailor; of neurotic taint; mother had slight attacks of depression; father's sister had a psychosis for many years; one brother was eccentric. The patient was a good student, but was erratic, unstable, and lacked application. He graduated from the public school. He states that he had been highly sensitive and unduly suspicious; that frequently while at school he thought his friends and schoolmates were against him on the least provocation, but he would soon discover his mistake and correct it. At twenty-two he fell in love, but his affections were not reciprocated because of a rival. Later, the patient married the girl in question and they lived together for nineteen years. His wife was loyal and affectionate. After marriage, on the slightest provocation, he would involuntarily, as he himself says, become jealous and suspicious of her, and imagined that she loved his former rival more than him. He frequently misinterpreted her statements, but after some remonstrance on her part he would admit that he was mistaken. At times he would be sullen and quiet. However, with a great deal of tact on the part of the wife, they got along fairly well until four years ago, when his wife developed some uterine disease and could not perform her marital duties as often as her husband desired. She appeared, moreover, to have developed an aversion in this matter, which caused many quarrels. The name of the former rival would be repeatedly mentioned, and on some occasions the wife would unwisely refer to the rival in a commendatory way. Thus the suspicion and fear that had lain dormant in his mind for many years began to shape itself into delusions. The wife, because of incompatibility, left him to live at her mother's home, which happened to be in the neighborhood where her former suitor lived. Such a coincidence confirmed his fears that something was going on between his wife and former rival. He engaged detectives to follow her and this man. On many evenings he would conceal himself in the neighborhood and spy upon them. He never obtained any evidence beyond the fact that the man once or twice passed the house in which his wife lived. But this was enough to confirm his suspicions. He wrote many threatening letters to the man, accusing him of improper conduct, adducing, in proof of the fact, the passing of his wife's house and other facts equally insignificant and irrelevant. A reconciliation with his wife was effected with many promises on his part, but the condition gradually became worse. He would come home unexpectedly at different hours, search the house, accuse his wife because the furniture was slightly disarranged, become suspicious of his food, misinterpreted every movement of his wife, however insignificant, as being indicative of her guilt.

He was brought to the hospital after a violent outbreak. He had a fixed delusional system regarding the infidelity of his wife which he endeavored to support with facts which were as absurd and insignificant as those just cited. There was no alcoholic history and no hallucinations were present. He was an excessive smoker. His friends interfered, and it was arranged that he was to be removed from his wife, and with some pleasure was discharged from the hospital with the understanding that he was to report from time to time. Soon after this his wife underwent a general obstetrical operation for the uterine disease, at which the patient had never believed. This seemed to arouse him and gave the new basis to the capacity of his delusional system. The new basis, however, from his own mind, led to the gradual development of his delusional system, and he in the delusional mood and has since remained accurately well.

(c) The third subgrouping includes those individuals who are constitutionally inferior, who, under the stress of adverse conditions as here out-

lined, are attacked with a paranoid complex. Constitutional inferiority is here considered as a lack of full mental development rather than the condition of disequilibrium, which is present in the psychopath. These patients, owing to limited intelligence and education, when placed in an environment favorable to the development of paranoid ideas, form a delusional system of a very limited type, due to their lack of full critical power. These delusions are based on actual facts and occurrences which are misinterpreted, and the relations of the different occurrences are misjudged. No hallucinations occur unless due to extraneous influences.

They differ from the preceding group in that they make no successful effort at explanation when confronted with the inconsistency of their ideas, but simply make the positive statement that such are the facts. Their delusional system is more limited, and shows no tendency to further progress. They are more amenable to treatment, and with proper preventive measures their false ideas can be made to disappear. As a type of this group the history of the following case may be given:

CASE III.—Male, twenty-four years old; colored; limited education and intelligence. His mother had given birth to an illegitimate son, whom she left in the care of her parents in a southern State when she came to New York. Later she married, and the patient is the first fruit of the marriage. A few years after her marriage the husband discovered her early history, and after considerable friction became reconciled to take the child from his grandparents and care for him at home. He was brought up as the elder brother of the patient, and turned out to be a rather unruly and reckless boy. His conduct, in addition to the friction between his father and mother, prompted the mother to put him into a home, where he was kept until he was eleven years old. He was then left to shift for himself, and naturally bore considerable enmity towards her. The patient frequently met his halfbrother, who was above the average in intelligence, and they became quite friendly. The elder brother, taking advantage of his brother's simplicity, poisoned his mind against their mother, stating that she was cruel and had abused and abandoned him to an institution; he also told his younger brother that he was treated in this manner because the patient's father was not his father, and his mother, to conceal her shame, had taken steps to dispose of him.

The patient then became quite unruly himself, worked irregularly, stayed away from home a great deal, so that his mother thought it necessary to discipline him. Her action was misinterpreted by the patient, who, remembering the case of his halfbrother, began to become very suspicious, and conceived the idea that his mother was trying to do to him what she had done to the brother. Unfortunately, by way of intimidation, she declared that unless he behaved she would be compelled to place him in an institution. During his interviews with his halfbrother, who lived away from home, he narrated his experiences at home and was assured by his halfbrother that he was about to receive the same kind of treatment that he had. This fact intensified his suspicion still more, until he began to misinterpret every action made by his father and mother as being unfriendly toward him. He naturally became more unruly and disobedient. Matters went so far that it was impossible to get along with him at home, and his parents placed him in an institution. This unfortunate step more firmly fixed the ideas of persecution which were already forming. In the light of the experience of his halfbrother he finally came to the conclusion that his mother was not his right mother. Thus, he formed a delusional trend, fairly well systematized but very limited. While in the institution he was a model inmate, worked regularly, and was very obedient and careful in his observance of the rules of the institution. As soon as he was taken home, however, he immediately began to show his suspicions, misinterpreting every act on the part of his mother, father, and little brothers, distorting the facts in the light of his de-

lusions. This condition was intensified by the conduct of the family, which, of course, was one of resentment and severity. His suspicions increased, until he would not eat with the family, and sometimes he would wait until some one else had tasted the food before he would partake of it.

As his mother thought he was probably mentally unbalanced, the patient was first brought to the hospital for examination four years ago. At that time he showed a limited system of delusions, that his mother was mistreating him, that she was trying to get rid of him and place him in an institution; that he was not treated like the other children in the family; and that he overheard many conversations between his father and mother relative to himself which convinced him that they were about to do away with him. He stated that he had taken precautions to protect himself and that he had at times refused to eat. He firmly believed that his mother was not his own mother and that this was the reason he was being treated in this manner, and as a proof of his contention he cited the case of the elder halfbrother. When his ideas were attacked, his defense was extremely weak; he made no intelligent attempt to defend his mode of reasoning, simply asserting that these things were so. He was sent home with some advice, but shortly returned, as it was impossible for him to get along at home. Finally an arrangement was made whereby he was to stay away from home, and not to communicate with his family in any way whatever. A place was found for him where he worked for over a year without having any trouble whatever, and he gave perfect satisfaction. His employers were much pleased with his work and could see no sign of mental derangement or even peculiarity. At this time his mother, thinking that he was quite well, wished to take him home, forgetting her former promises. She induced him to go back and live with the family. For several months he seemed to get along, but his ideas of injury again took possession of him and so dominated him that during one of his excited periods he attacked his mother, for which he was committed to the Work House. He remained there six months and proved to be a model inmate; but upon examining him there, I found that his delusions were not only intact, but much more fixed and intensified. After he left the Work House his mother again induced him to live with them. Within a few weeks he became excited again, reacted to his former false ideas, and had to be committed to the hospital. At this examination his delusional trend had not only increased, but he was more convinced than ever that his mother was not his right mother, because she had committed him to the Work House. He again agreed to live entirely away from his family, and for several months has been working, perfectly contented and happy. His employers are much pleased with the work he is doing. He has kept away from his home and has not shown any animosity toward his parents.

The tentative groupings here suggested have been of great aid to me in clinical work, especially in the question of prognosis and treatment. To the layman paranoia is the most widely known of the insanities, and likewise with it, is associated the idea of incurability. Physicians are also convinced of its hopelessness, and we all share this preconceived idea of certain cases in the paranoia group, so that we pay comparatively little attention to them in a therapeutic way. They are usually immediately sent to hospitals for the insane, where they form a large part of the permanent population and receive scant medical care. It is usually considered a waste of time to pay much attention to this class of cases. There is no doubt that for most of the groups of cases herein noted a chronic progressive process is at work, but are not some of those afflicted amenable to treatment, and cannot their condition at least be ameliorated? Or can we not by prophylactic measures in one predisposed to the disease prevent an outbreak?

For example, the group of psychopathic paranoiacs where the delusional formation is psychogenetic, or endogenous in the sense of Friedman,

can undoubtedly be benefited by treatment in the way of judicious regulation of the patient's life, looking particularly toward the removal of the causes of irritation, which have given rise to his false ideas. In some of these cases sanatorium treatment is advisable, whereas in others it would only intensify and aggravate the condition.

In the case of the young colored man here reported, hospital treatment, I am certain, would have settled and fixed the ideas, just as his remaining in the midst of the irritating conditions at home would have aggravated them. His condition, while at the workhouse, clearly demonstrated this.

The same applies to the case of the jealous tailor who was a psychopath and who was attacked with a delusional system in close relation to his former life and personal traits. It is possible that incarceration in a hospital would have intensified and fixed his ideas more firmly.

The same holds true in a restricted way of the deteriorating group to which the case of the school teacher belongs. She will perhaps eventually deteriorate so that it will be necessary to care for her in an institution. However, she has been getting along fairly well for many years, except at intervals, when her somatic false perceptions, upon which her delusions seem dependent, become stronger. Under supervision, at the time of her periodic outbreaks, it might be possible for her to get along outside of an asylum for many years. In other words, in the clinical grouping, as here suggested, an attempt is made to distinguish those cases for which, perhaps, something can be done, and avoid the mistake on our part of regarding the whole group as made up entirely of the severer and more hopeless forms.

What is the relation of the genuine chronic paranoia in the Kraepelin sense to these milder types? Is it possible that they differ only in degree? Can anything be done for the so called chronic progressive paranoia in the early stages and before it has made much progress? These are questions that recur to me very frequently. I cannot recall one single case of this type of paranoia, in which psychoanalysis of the delusional system did not show, that at its very inception conditions most favorable to the development of the disease were present. One can almost invariably find that most of the unfortunate occurrences followed in rapid succession, and that the patient was treated by his friends in the very way he should not have been for the amelioration of the abnormal ideas in their formative stage.

A grouping of this kind has another advantage from the medicolegal standpoint. Most of the insane patients who come in conflict with the law present paranoid ideas. As there seems to be much difference of opinion among alienists as to what the term paranoia stands for, for the reasons already discussed, there are apt to be decided differences of opinion expressed from the witness stand. For one the term paranoia means the whole group, for the other only one subdivision of the group. One who has one of the milder types in mind, which at times recovers, contends that a patient suffering from paranoia may recover; where-

as the other, having in view the chronic form, insists that it never recovers and is progressive. Some have in mind the paranoid ideas expressed by a senile alcoholic, and term it paranoia; others observed paranoid ideas in a manic depressive and call it paranoia; while still others, observing a patient suffering from mild alcoholic hallucinosis with paranoid ideas, term it an acute hallucinatory paranoia, in the Mendelian sense, and so the confusion goes on. Thus, for lack of a proper agreement as to what each alienist means, when he uses the term paranoia, there results the confusion of the court and jury, to the discredit of the medical expert in general.

In summarizing it may be said:

First—That the grouping of paranoia from only a symptomatic point of view is unscientific and untenable.

Second—That when measured by complete clinical criteria the paranoia group is reduced to about ten per cent. of all insanities which seem to have some fundamental characteristics in common.

Third—That this restricted group is composed of two essentially different types, namely, deteriorating and nondeteriorating or degenerative, which should not be confounded.

Fourth—That these two general groupings, owing to our present limited knowledge, may only empirically and arbitrarily be divided into other subgroups: (a) For clinical and therapeutic convenience. (b) To bring about an understanding among the alienists in order to avoid confusion in medicolegal questions.

## NEURALGIA.

*Its Specific Treatment with Chloroform Subcutaneously.\**

By S. ORMOND GOLDAN, M. D.,  
New York,

Fellow Academy of Medicine, New York City.

The importance and scope of the subject of neuralgia is so extensive that with the limited time at my command I wish to bring to your attention especially the method employed by me for the past ten years in the treatment of this painful malady. The great variety of neuralgias treated and the technique employed make the method practically original. It is a fact, however, that isolated cases of neuralgia have been previously treated with chloroform, though generally at present it has fallen into disuse.

While the subcutaneous injection of chloroform is exceedingly easy of application, all patients will not submit to it. The method produces certain reactions, such as redness, swelling, etc., which seem alarming to some. In acute neuralgia, where the cause is easily determined, general medical treatment will usually prove effective. Where, however, after all palliative methods have been unsuccessful, the patient will be willing to submit to almost any treatment which will relieve him of his suffering—in these cases the treatment with chloroform will prove almost always successful, in fact certain. It is for this reason I have termed the method specific.

\*Read before the Section of Medicine at the New York Academy of Medicine, April 27, 1908.

FIG. 1.—A, Deep injection; B, superficial injection.

In considering the ætiological factors in neuralgia we may mention anæmia; exposure to cold and wet; change of seasons; vitiated atmosphere; periodic, malarial and nonmalarial; inhalation of irritating gases; inhalation of anæsthetics; neuritis; organic and inorganic poisons, alcohol, lead, etc.; autotoxæmia; syphilis.

I wish to direct attention to a frequent type of neuralgia, "the periodic." Quinine will cure many of these cases, others will respond to the coal tar remedies. Where these attacks, instead of appearing at the same time every day, seem to be deferred

FIG. 2.—Infraorbital and maxillary branches involved.

to a time later and later each day, we can assure the patient his neuralgia will quickly cease; these are the cases where the coal tar remedies prove more successful than does quinine.

Autotoxæmia, particularly of the intestinal type, is one of the most prevalent causes of not only neuralgia, but rheumatism, and frequently we find both diseases coexistent. Fortunately in these cases the same remedies prove equally efficient in both diseases.

Some of my cases treated with chloroform can hardly be classed as pure neuralgia, as lumbago, which more properly is a muscular rheumatism and neuralgia combined. Some of the most brilliant results with the method of chloroform injection have been secured in lumbago.

The classes of neuralgia subjected to the chloroform treatment may be stated as follows: Trifacial neuralgia; supraorbital neuralgia, first branch; in-

FIG. 3.—Torticollis

fraorbital neuralgia, second branch; mandibular neuralgia, third branch. Torticollis. Brachial neuralgia. Intercostal neuralgia. Sciatica. Lumbago. Inguinal neuralgia. Coccygodynia. Plantar neuralgia. Tendinous neuralgia.

*Technique.*—This consists in injecting pure chloroform, in quantity varying from two to ten minims, into the site of the neuralgic area with an ordinary sterilized hypodermic syringe with aseptic precautions.

#### Results.

Facial neuralgia.—In general practice one does not see facial neuralgia every day. It is about the most distressing sight one is called upon to witness. My experience covers seven cases treated with chloroform; of these three were of the supraorbital nerve, one infraorbital branch, and three of the infraorbital and maxillary branches combined. The treatment resulted instantly in almost absolute ces-

FIG. 4.—Intercostal neuralgia.

sation of pain. One patient, who has kindly presented himself for demonstration, had received some months previously injections with osmic acid. Another patient, who left the city before I had fully applied the treatment, wrote me from a Mediterranean city that all pain ceased from the first injection (infraorbital), the second injection (maxillary) caused some pain when chewing, which lasted only a few days. The procedure in all of these cases was to inject two to five drops in five or six sites about one half to one inch apart in the painful area. Neuralgia of the fifth pair has always been difficult to account for; the teeth have always been looked upon as an ætiological factor, the patients having one or more teeth removed, only to find the pain still persist. The probable explanation is, while the teeth

FIG. 5.—A, Lumbago. B, Sciatica.

may at times be the cause of pathological changes in the nerve filaments, the neuritis progresses long after the original cause has ceased. In the cutaneous cases it seems to me that only small parts of nerve filaments are the seat of neuritis and reflexly cause involvement in large sections of contiguous nerves, out of all proportion to the extent of the filament involved. The fact that chloroform acts as a curative agent would indicate that the above explanation is the correct one, and how it acts I will presently state.

Torticollis is an exceedingly painful condition. Five injections were made in each of my two cases, with rapid but not instantaneous recovery in each case.

Brachial neuralgia.—I have treated three patients with complete relief immediately after fairly deep as well as superficial injections.

Intercostal neuralgia.—I have had seven patients; all these were relieved immediately. Injections were made into the skin, as well as deep between ribs, with needle of syringe pointing from behind forward and upward, or from before, backward and upward.

Sciatica.—I have treated five patients with this

FIG. 6.—Proximal neuralgia.

method; three of these required repeated injections, with perfect cure. One patient, while greatly benefited, refused to have subsequent injections. One patient received no benefit—in fact, was temporarily worse; it is interesting to note that this patient had not solely sciatica, but a phlebitis, involving both limbs and including the veins of the pelvis. Sciatica was greatly improved as a result of improvement of the phlebitis with the treatment with the waters at Bagnole del Orne, France.

Lumbago.—I have had patients come to my office almost creeping, to leave within a half hour perfectly free from pain and perfectly erect; these had no recurrence of lumbago. Up to the present time fourteen patients have been treated by me with chloroform, eleven had but one series of injections. One I am unable to locate, he was improved at the time; and one was a somewhat peculiar case. This patient had not a typical lumbago, but muscular

pains over the entire back; he was injected repeatedly, with more improvement than he had received in sixteen years, as he stated. His treatment took about a month; for obvious reasons he did not return. I concluded he had the lumbago habit.

Inguinal neuralgia.—Two patients; superficial injections, with perfect results.

Coccygodynia.—I have treated three patients with this method; one of these cases was a male. This patient could not sit, and from his history he must have injured himself while riding a bicycle; his symptoms indicated a true coccygodynia. A deep injection in the region of the coccyx relieved the condition completely and permanently. Both female patients required more than one injection; in one two, in the other six injections were made, with no return of the trouble.

Plantar neuralgia.—This is an exceedingly painful condition in the sole of the foot. I have seen several of these patients, but have had the opportunity of applying the injection method in but one. The patient was considerably benefited. He left the city, but I subsequently heard from him that while he remained as free from pain as at the time the treatment was applied, his condition was at a standstill. The injections made in this patient were subcutaneous. I believe had it been possible to make several injections, some deep, this patient would have been completely cured.

Tendinous neuralgia.—A fairly large number of patients recovering from attacks of acute rheumatism, with absence of elevation of temperature, complain of pain and stiffness about the joints. As near as I could determine, this pain is located in the tendons about the joints; it persists for a variable time. Small injections of chloroform are made into the tendons as near as possible, with generally beneficial results; the patients all became well; no doubt with time they would have done so without the injections. This procedure was employed by me in thirty-two patients.

Explanation of the effects produced.—Neuralgia is said to be a cry of the nerves for blood. If this is so, chloroform, by causing an inflammation (I might say a reparative inflammation), evidenced by redness and swelling, determines a new supply of blood to the nerve filaments through the formation of new capillaries. While other agents have been used for injection in certain neuralgias, my results have been universally satisfactory with chloroform. Any persistent pain which has not yielded to other medication, chloroform is recommended with almost certainty as proving efficacious.

#### Conclusions.

The nearest approach to a specific in neuralgia is, in my opinion, chloroform.

The method has in my hands proved to be devoid of any untoward effects, both immediate and remote.

Chloroform injected locally has no systemic effects. It has a local anæsthetic effect, which is desirable.

Superficial injections often act with certainty, even when the pain seems to be deep seated.

## THE MODIFIED BLOOD CLOT IN MASTOID SURGERY.\*

BY SAMUEL McCULLAGH, M. D.,  
New York.

Although the value of the blood clot method of healing wounds has been proved both in general and mastoid surgery, it is strange how little attention has been paid to it by aural surgeons if an opinion may be formed from published reports, or rather the lack of them. Undoubtedly the explanation is not far to seek. At first thought, to a surgeon, perhaps nothing could seem more irrational and foredoomed to failure than the proposal to sew up the wound made in the Schwartz operation and expect healing by what is practically first intention. The approach to so radical a departure from surgical principles is usually made in a spirit of doubt and with the expectation of failure. Should such be the outcome no feeling of surprise is experienced, the expected having happened, but rather a feeling of relief that no untoward result has followed, and a hasty return is made to the old method. The writer feels that with care in the application of technique and selection of cases the mastoid wound should be perfectly healed within a week to ten days in at least seventy-five per cent. of cases so treated. Fallacious as most prophecies in the field of medicine have been, except those as to its progress, it seems as though the ideal mastoid operation has been attained. Doubtless, improvements in the method of exenterating the bone will come, and, doubtless, fewer cases will come to operation, but for those cases which do it is hard to see where, with the exception noted, further advance is possible.

The writer will confine his remarks in this paper to a consideration of this method as applied to the Schwartz operation only. He has nothing new to suggest. His object is merely to reiterate and emphasize the points already made by those who have discussed this subject. In rather a cursory examination of the literature so few authors have reported cases treated by this method and the papers of those who have used it are so highly eulogistic that it is a cause of great wonder that a method that will shorten the convalescence from a mastoid operation from four to even twenty weeks and dispense with the necessity of dressings should not have been more eagerly tried out thoroughly and given its true standing in aural surgery.

The factor militating most against a more extended trial is, undoubtedly, the knowledge that it is impossible to render the wound aseptic and that blood serum is a very good culture medium. We seem here to have ideal conditions for the propagation of bacteria—heat, moisture, a good medium, and bacteria. Every surgeon has seen so many wounds break down, where the prospect for healing by first intention was so bright, and experience had taught him to expect it, that it is not to be wondered at that he looks askance at the proposition under consideration. Reik (1) has thoroughly discussed this phase of the subject in his paper on The Blood Clot Dressing in Mastoidectomy, Physiologically Considered. He says: "The nor-

\* Presented as a candidate's thesis to the American Laryngological, Rhinological and Otolological Society.

mal human blood possesses bactericidal power, varying in degree in its antagonism to different microorganisms; this property of the blood is greater after it is drawn from the vessels than while circulating intravascularly; the microbe destroying substance is found in the serum, but is produced by the leucocytes; certain chemical changes in the blood may be induced either to increase or diminish its bactericidal power, and this property of the blood naturally diminishes after the clot is forty-eight hours old.

This microbe destroying substance, according to Vaughn and McClintock, is nuclein. The bactericidal power seems to be present in freshly drawn blood only when it is alkaline in reaction. The nuclein acts only in an alkaline serum. If alcohol be added to the blood, the bactericidal property is destroyed through the precipitation of the albuminoid constituent. Bichloride of mercury likewise has a deleterious influence on the bactericidal property of the blood serum."

The fact of this bactericidal action of freshly drawn blood being recognized, it is easy to understand how absolute asepsis is not a *sine qua non* for the successful outcome of the blood clot method. This statement should not be taken to indicate that the slightest lapse from the strictest antiseptic precautions should be allowed either before, during, or after the operation. In fact, they should be redoubled.

Regarding the manner of healing, Reik further says: "The blood flowing into the wound cavity rapidly clots and the fibrous framework of this clot constitutes the scaffolding on which the new tissue is built. Fresh granulations spring from the wall of the cavity and grow out into the clot, forming new fibrous connective tissue, the nature of which is further altered to accord with the character of the surrounding cavity walls; that is, if the wound is made in bone, osteoblasts are sent out from the bony walls or periosteum to convert the fibrous substance into osseous tissue. Just how early this osteoblastic activity commences is not known, but such cells have been observed to form within forty-eight hours after the operation, and it is certain that granulation tissue grows more rapidly into a healthy blood clot than into space. It is plain then that Nature may be greatly aided in the reconstruction of destroyed tissue by providing an excellent framework on which to build, and leaving her only the task of furnishing vascularity and new tissue cells."

*Technique.*—The writer will omit any reference to the preliminary preparation of the patient, as it differs in no way from that usually employed. Neither will anything be said of the operation itself, except that this method of after treatment obviates the necessity for the removal of any healthy bone from the posterior wall of the canal. It may be well here to urge the necessity for gentle treatment of the periosteum, care being exercised that the incision through it shall be a clean one and that it is not maltreated by rough dissection. The use of the hoe-shaped periosteotome is indicated for this step of the operation. All ragged edges should be trimmed off before the insertion of the suture. Marked infiltration of the soft tissues overlying the

bone is no contraindication to suturing, as union by first intention will take place when this is present.

*No antiseptics should be used at any stage of the operation on the bone.* If moist sponges are desired they should be wrung out of normal salt solution.

Silver wire and silk worm gut are the materials of choice for suturing. The writer has used the latter entirely. A heavy grade is not necessary, as with the method of suturing employed there is very little strain on the stitch. A medium sized Hagedorn needle curved through an arc of 180° will be found most convenient for the insertion of the suture.

Before the mastoid operation it is well, in every case, to make a free incision in the drum membrane. This incision should include the mucous membrane on the internal wall of the tympanum. The ear is then irrigated thoroughly with a solution of bichloride of mercury, followed by normal salt solution.

When the removal of bone is completed the cavity should be flushed out with a normal salt solution and sponged dry. A running subcutaneous suture is then introduced. This is started at the most convenient angle and the wound is laced to the other angle, the stitches not exceeding a half inch in length. If larger stitches are taken the edges of the wound cannot be approximated accurately. The ends of the suture are left long. A piece of rubber tissue about an inch long, that has been folded four to six times to a breadth of one eighth to one fourth of an inch, is now placed between the last two stitches at the lower angle of the wound so that it projects about a half an inch into the wound cavity and the incision is closed by traction on the ends of the suture. The edges of the wound are coated as accurately as possible and the ends of the suture knotted together loosely in such a manner that there is no strain on the wound. This is merely for convenience of removal. They can be cut off, provided a sufficient length is left for grasping at the time of removal. A second drain of rubber tissue is inserted in the canal and a dressing applied.

The drain that is inserted into the wound cavity is not placed at the bottom of the wound, but very superficially under the line of suturing. Its object is merely to allow escape to the excess of serum expressed from the clot and it remains in place only twenty-four to forty-eight hours. The writer can see no necessity for the inclusion of gauze in the rubber tissue—the so called cigarette drain—as perfect drainage occurs along the plain rubber tissue and the danger of the gauze acting as a cork is obviated. For the same reason the middle ear is drained in a similar manner.

One last word about the introduction of the suture. Very great care should be exercised in this step to be sure that none of the layers of the skin are included, as infection would be liable to occur, due to the bacteria resident in the deeper layers of the skin. This has, doubtless, been the cause of failure in many unsuccessful cases. Allowing a factor of safety, the suture should be introduced as close to the skin as possible, in order that reapproximation of the edges may be accurate and the resulting scar as inconspicuous as possible.

*After Treatment.*—At the end of twenty-four hours the outer dressing is removed and will be found to have absorbed quite a little serum. The drain is removed and is allowed to stay out unless there is a suspicion that the discharge is in any degree purulent, in which case it is reinserted, though this time only through the lips of the wound. If the secretion is frankly purulent, the lips of the wound are separated for a short distance with a probe, the cavity wiped out with dry cotton and the drain reinserted. In all cases the drain is removed from the canal, which is wiped dry with cotton and the drain reinserted.

At the end of forty-eight hours the wound is again dressed. If the drain has been removed at the end of twenty-four hours and all is well the skin wound may be found entirely healed and the stitch is removed. This should be done by first withdrawing it a short distance from the tissues, cutting it as close to the skin as possible and then making gentle traction upon the other end. The canal is treated as before and the patient is well, except for a daily cleansing of the canal with dry cotton until the discharge has ceased, which should be within a week or ten days. The wound should be protected with a dressing and bandage for several days. The writer has thought it unnecessary to reiterate his statement that the most minute antiseptic precautions should be observed in every step. Antiseptic solutions can be used as freely as fancy dictates after the first twenty-four hours, provided that they are not introduced into the wound cavity or canal.

If the drain has been reinserted through the lips of the wound on the first day on the suspicion that all is not going well and that suspicion has not been justified it should be removed permanently and the patient treated as indicated for an uncomplicated case, the suture being allowed to remain in place twenty-four hours longer.

In those cases where infection has occurred both ends of the suture are cut off, as already described, and it is removed by traction from the point where the drain was inserted. By this manoeuvre the chance of the extension of the infection to any part of the clot that has held is lessened. If the whole clot has broken down this precaution is unnecessary. The wound is opened with a probe as freely as desired, wiped dry, and drainage inserted if any of the clot remains. Otherwise, the wound is treated so as to encourage healing by granulation in the usual way.

A sudden rise of temperature after the operation should not be taken, *per se*, as a cause for the immediate removal of the suture and reopening of the wound. Unless there is local evidence, such as redness, pouting of the lips of the wound, or frank purulent secretion, it is well to wait for a time to see that no other condition is responsible for the temperature curve. A reference to Case II will illustrate this point very well.

*Indications and Contraindications.*—Perhaps the quickest way to reach the class of cases in which this method is indicated will be to eliminate those cases in which it is contraindicated, as even its warmest advocates will not contend that its applica-

bility is universal. Success cannot be anticipated in diabetes, but the writer can see no reason why it should not be attempted in other constitutional diseases. Sprague (2) gives as contraindications acute infectious diseases, tuberculosis, diabetes, and other chronic constitutional diseases. The writer would have no hesitancy in striving for primary healing in all cases suffering from the diseases enumerated, except diabetes. Even if the vitality is at such a low ebb that there seemed no probability of success, should healing by first intention, or even partial healing, occur, the drain of a large suppurating area is eliminated or diminished, and a further tax on the already low vitality is avoided. Should the attempt fail nothing is lost, but the very painful and exhausting first dressing is dispensed with. Regarding the partial healing of the wound Blake (3) says: "Later experience has shown that it is perfectly possible for a blood clot to remain intact in one part of the evacuated mastoid and to become septic in another, this forming a basis for primary external healing in one portion, and in another, breaking down and necessitating the establishment of drainage for the region involved, the healing of this portion of the mastoid cavity being effected by the slower process of the formation of granulationata."

The great contraindication is, of course, intracranial involvement. Leaving out of consideration brain abscess and leptomeningitis, the question as to whether intracranial complications are an absolute contraindication is still an open one, and one that will demand more experience with this method before a definite answer can be given. Sprague reports three cases of sinus thrombosis in which the blood clot method was used after the thrombus had been removed with healing in about two weeks, and Bryant (4) one of epidural abscess with the same result. The writer admits that he would have a great deal of hesitancy in thus dealing with a case of lateral sinus thrombosis. In cases where a localized meningitis is the complicating factor, if the condition appears to have existed for a comparatively long time and the process is localized he would sew the wound up. Otherwise he would resort to packing. In view of the results of the writers quoted above the absolute contraindication is not intracranial, but intradural, complications. In cases in which the dura or sinus have been exposed there should be hesitancy in adopting this line of treatment.

In discussing contraindications Sprague in his paper says: "If streptococcus is present in pure culture and operation is demanded before the opsonic index of the blood is sufficiently high to resist the infection, or nature has not had time to throw up her fortifications around the local process, the blood clot should not be attempted, as not only the clot becomes infected, but the virulence of the organism is so great that the whole wound suffers more or less. The stitch holes and along the line of incision and every freshly opened area is in forty-eight hours covered with a fibrinous exudate. If we have no bacteriological examination to help us out, the duration of the disease from the primary otitis will be a safe guide, and, all things considered, is probably the most reliable, even when laboratory aid is available. It seems to require on the average

about ten days from the onset of the middle ear trouble for nature to do her work of fortification. In my experience all these wounds do better after this period, and really the cases which have gone on three weeks do the best of all."

With the exceptions already noted the blood clot method is indicated in all cases of acute mastoiditis. Let us consider a little more at length the advantages of the blood clot and why it is indicated. The first and most important is the shortening of the time of convalescence and the elimination of the pain and distress of postoperative packing of the wound. This advantage is particularly gratifying in the management of nervous patients and children. The writer ventures to say that there is an element of selfcommiseration mingled with the pity the surgeon feels for the child upon the operating table as he thinks of the troublous times in store for them both during the after treatment. To one who has had a successful result with the blood clot the result is so gratifying that there would be a tendency to overstep the bounds of conservatism were not the contraindications so sharply defined. The only thing attended with the slightest degree of pain in the whole after treatment is the removal of the stitch, and that is so slight that it can be disregarded. Even in those cases in which the success of the clot is only partial, much time and discomfort, if not actual suffering, are saved. Lastly, in those cases in which the failure is complete no time has been lost, no untoward effects have been experienced, and the very painful first dressing has been dispensed with.

The element of the length of time required for healing has already been referred to several times, and the saving is so tremendous that it seems unnecessary to urge it further, but it would seem impossible to lay too much stress on the reduction of a convalescence from a minimum of three to four weeks and a maximum of several months to forty-eight to ninety-six hours, exclusive of the middle ear condition.

The gain from a cosmetic standpoint is also very great. There is no displacement of the auricle and no unsightly depression back of it. The cavity in the bone is entirely filled up, the contour restored, and all that remains to show that the operation has been performed is a faint linear scar. Reik says that in such a comparatively small cavity as the mastoid it is probable that in some cases the fibrous tissue is entirely converted into bone by the osteoblasts.

*Illustrative Cases.*—The writer cannot present a large number of cases in which this method has been used, but in those cases in which it has the results have been so gratifying that he feels that too much cannot be said in favor of a trial of the method. There is no need of giving the history of those cases in which primary union was obtained, as nothing is to be said beyond what has already been noted. However, three of his cases have presented points of interest which it may be interesting to note as illustrating some of the contingencies that may arise.

CASE I.—W. G., age two and one half years. At the time of operation the soft parts over the mastoid were *admitted* to a thickness of at least half an inch. At the time of the incision the tissue seemed slightly purulent and dense. The incision was made. The character of the discharge persisted, and

although about ninety per cent. of the wound healed by first intention a small sinus persisted. This sinus was just large enough to admit a probe and at its bottom bare bone was detected. Local treatment and drainage were persisted in for about two months, no packing being used at any time, with ultimate closure of the wound. Cosmetic result excellent. Middle ear dry in two weeks. While there was no saving of time in this case there was a marked saving of pain and discomfort, and the writer considers it a successful result in that sense.

CASE II.—A. L., age six years. This case was a very puzzling one. The patient came to the hospital with a history of an acute otitis media of a week's duration, for which a paracentesis had been performed the day before admission. The discharge from the middle ear was free. The patient was under observation for two days before operation. On the day of admission the temperature rose to 104.4° F. and fell, the next day, to 99.2° F. The next day it rose to 103.4° F. and four hours later was 98° F. There was no chill or sweat accompanying these fluctuations of temperature. The operation was performed on the second day after admission, when the sinus was exposed and found apparently normal. The mastoid contained pus and granulation tissue. During the week following the operation the temperature was very irregular, ranging between 104.4° F. and normal. The wound was examined daily, but seemed to be healing so nicely, there being no pus and no redness of the edges, that, although drainage was allowed to remain, the wound was not opened up. The main thing that caused this course to be pursued was the general appearance and condition of the child, who had not the slightest appearance of sepsis. Malaria was thought to be the cause of the irregular temperature, but there was no enlargement of the spleen and examinations of the blood for the plasmodium were negative. A distinctive count gave no clue. About ten days after the operation the patient complained of severe pain in the left side of the chest, accompanied by a hard, dry cough, and a sudden rise of temperature to above 104° F. A larval pneumonia was suspected, but all symptoms passed off in a few days and the temperature gradually returned to normal, where it remained until the patient's discharge. The drain was left in place for two weeks, and in less than three weeks the wound was entirely healed and the middle ear dry.

In this case the temptation to reopen the wound and seek the cause of the irregular temperature there was naturally very great, and had the patient not been under observation for forty-eight hours prior to the operation this would undoubtedly have been done. The general appearance of the child argued so strongly against a septic condition that this, fortunately, was not done. This aptly illustrates the fact that a postoperative rise of temperature should not be attributed too hurriedly to the sewing up of the mastoid wound unless local symptoms are present.

CASE III.—A. G., adult. Primary union occurred in this case, but the patient continued to complain so much of pain in the temporal bone that the wound was partially reopened. The findings were negative, and the edges of the wound were allowed to fall together. Prompt healing again took place, the middle ear being dry before the end of two weeks.

In conclusion the writer would contend that this method has passed the experimental stage, and would make a plea for its more extended trial and a report of results obtained, especially unfavorable ones, so that the limits of its application may be more clearly defined. There is still room for experiment in this particular, but the writer feels that within a very short time packing of the mastoid wound in uncomplicated cases will be considered as poor surgery as a mere opening of the antrum without removal of all diseased tissue, and as much so. He would strongly urge that one or two failures be not allowed to deter from a repetition of the trial, as

there is no reason why results identical with those reported should not be obtained by any surgeon who attends with care to his technique.

### AN ANALYTICAL STUDY OF SIX HUNDRED CASES OF ANÆSTHESIA.

BY HAROLD L. SPRINGER, M. D.,  
Wilmington, Del.,  
Surgeon to the Delaware Hospital.

In presenting for your consideration a review of this series of cases, I shall not attempt a systematic study of this subject for various reasons, but shall confine my remarks to those points that have impressed me as being of greater interest and importance in the administration of anæsthetics, particularly ether and chloroform.

Ether was given in eighty-eight per cent. of cases and chloroform in twelve per cent. Of those given ether, two per cent. were begun with chloroform. Never more than a drachm of chloroform was used and often less, ether being substituted as soon as the patient became quiet.

Ether was preferred in cases of organic disease of the brain, heart, and bloodvessels, and chloroform in cases of lung or throat disease, alcoholic, and nervous persons, and where great rapidity was desired.

The average time to produce anæsthesia was ten minutes, varying from three minutes in several instances in children to twenty minutes in more difficult cases. The patient was considered anæsthetized when complete relaxation was obtained. The pupils were not used as an index at this stage, for in some cases they remained responsive to light during the entire operation. As a rule, however, moderate secondary dilation of the pupils is the best guide to complete unconsciousness, and my experience leads me to believe that the interval of safety between the loss of the corneal reflex and failure of perspiration and the heart, is greater than ordinarily supposed. I agree with Thomas, who says that the corneal reflex is not to be depended upon at any stage, especially if muscular relaxation is desired, for this reflex varies so much in different individuals that, on the whole, I think it is safer to ignore it altogether.

The total time that each patient was under the influence of the anæsthetic varied from fifteen minutes to four hours, the average being one hour and fifteen minutes.

The average patient gave the first definite sign of return to consciousness in five minutes after the anæsthetic was stopped. Children seemed to recover sometimes almost as soon as the inhaler was removed. In cases in which the patient is several

hours recovering are due to careless methods and to an overdose of the anæsthetic.

The average total amount of ether used was eight ounces, two and one half to produce and five and one half to maintain the narcosis. The average amount of ether used during the first hour was six ounces, and during the second hour was three ounces, and the quantity became less for each successive hour. In one case of this series the operation was of four hours' duration, and the quantity of ether used was five and one half ounces for the first hour, two and one half for the second, and one half ounce for the third and the fourth, making a total of a little over nine ounces for the four hours. In another instance thirty ounces were used in an operation of only one hour duration. The patient was an alcoholic and had taken ether before. It required more ether to produce narcosis in alcoholics and individuals who had taken it before. In several instances it was impossible to secure relaxation without the aid of chloroform. An extremely nervous person always required more of the drug than a less apprehensive one.

One of the greatest sources of annoyance to both patient and anesthetizer is the vomiting that occurs from ether or chloroform. It does not occur in every case, and it was this difference in behavior on the part of the patients that induced the writer to commence this record.

In this series of cases twenty-five per cent. of the total number of patients vomited at some time during the narcosis, and nearly all toward the end of it. Often it was the first sign of returning consciousness. A few times it occurred at the beginning. Vomiting rarely occurred after the use of chloroform or after ether when chloroform was used to start the anæsthesia, and when it did occur there was always noticeable an unusually large quantity of mucus. This hypersecretion was more marked when nervousness or excitement was present, and sometimes interfered seriously with breathing. Choking and struggling followed, and more ether was given. Thus, saturated saliva and mucus was swallowed in large quantities, and from these records the mucus would seem to be the cause of the trouble. In other words, the mucus and ether, by its irritant action on the stomach, caused vomiting. The figures are very suggestive. Twenty-six per cent. of the cases were associated with an excessive amount of mucus, and every one of the patients vomited. Twenty-four per cent. of the total number of patients vomited; the remaining two per cent. vomited from some other cause.

Vomiting may be prevented in some cases by directing the patient to drink one or two glasses of water about an hour before the operation, and prolonged vomiting may be stopped in certain cases by drinking one or two glasses after the operation. The latter acts the same as lavage, and lavage is a sure cure for uncontrollable vomiting.

For these reasons there seems to be strong cause to believe that in the large majority of cases vomiting is due to the irritant action of ether on the stomach, and that, while many patients will vomit in spite of all that can be done, the slow, careful administration of ether, drop by drop, will prevent it in many instances.

That form of vomiting that occurs sometimes at the beginning of the narcosis in cases of intestinal obstruction is a very serious complication, and it behooves the anesthetizer to be on his guard. It is really a regurgitation, and the patient literally drowns in his own vomitus. In cases of this sort the patient should be anesthetized in the Fowler position and the stomach washed out before the anæsthetic is given.

Aspirative pneumonia is a serious sequel of vomiting, although fortunately very rare. It is not, however, the usual type that follows the administration of an anæsthetic. Pneumonia practically never occurs after the use of chloroform, and very rarely after ether. In the majority of cases it is not a true pneumonia, but is, as Murrell notes, a catarrhal bronchorrhœa followed by œdema of the lungs. True pneumonia does occur, however, and is due to the irritation of ether or unnecessary exposure and chilling of the patient. It is especially liable to follow the use of ether in a patient that has a bronchitis. It rarely occurs in private as compared with hospital practice, and may be guarded against by having the mouth cleansed and the inhaler clean, by having the head turned to one side in order that fluids may escape from the mouth, and by using pure ether and as little of it as possible.

Oxygen was administered in four per cent. of all the cases as a necessity, and in 100 cases routinely, to note the effects. The results in every instance were very satisfactory, and when chloroform was used, oxygen was often indispensable. The return to consciousness was undoubtedly more rapid than when oxygen was not used, and in cases of respiratory embarrassment, the change of color from bad to good was often truly miraculous. I have come to regard oxygen of so much importance that I would rather be without drugs than without oxygen. The value of the anæsthetic is increased as regards safety to life without decreasing the anæsthetic effect. Gwathmey proved this by his experiments on cats. His figures show that, regardless of the air used, animals lived twice as long with oxygen as when air alone was used. The same experiments show that a mixture of chloroform and oxygen was more than twice as safe as a mixture of chloroform and air. This seems to indicate that chloroform is safer than usually believed, and, in fact, some authorities assert, as safe as ether, unless given by the inexperienced. At any rate, the use of oxygen with ether, and particularly chloroform, eliminates a large element of danger.

Struggling and extreme excitement during the first stage of anæsthesia may be avoided in ninety-five per cent. of cases, according to my statistics, by the drop method of administration and careful management. Thus one, if not the greatest, objection to ether on the part of the patient can be eliminated in this manner. Alcoholics will usually be an exception to the rule, as will persons who have taken ether before. In these cases if chloroform is used to commence the anæsthesia, the trouble will be overcome.

Eight and two tenths per cent. of the patients had taken ether before, varying from one to five times. They were all without exception more difficult to get under the influence of the anæsthetic. Capri-

hart's belief that the red blood cells assume an increased resistance to ether in the same manner that they do to other hæmolytic agents, such as toxins, is to my mind an untenable one.

The operations performed were of all varieties. Seventy-five per cent. were major operations, and eleven per cent. were fatal cases, death occurring within the next forty-eight hours. The fatal termination may have been hastened somewhat in a few cases, but death from the anæsthetic alone occurred in only one case. This was a man aged sixty years, who, after a long operation, died of œdema of the lungs.

The patient's general condition was carefully noted before and after the operation. The heart and lungs were gone over, the urine examined, and the pulse counted just before the operation. Ten per cent. had heart murmurs, although not one of the patients experienced any difficulty. Seven per cent. had a more or less severe bronchitis, and only two of them were attacked with pneumonia.

Eighteen per cent. of the patients required treatment during the operation or within an hour after it. Two and three tenths per cent. of those anesthetized were alcoholics, and gave trouble from start to finish. A peculiar erythema of the face, neck, and upper part of the chest was present in three and seven tenths per cent. of the cases. It appeared only after the use of ether and always during the first stage of the narcosis. It persisted for from five to thirty minutes and gradually faded as the anæsthesia progressed, until it had completely disappeared.

The method of administration was the drop one, and the Allis inhaler was used in the large majority of cases. Sterile gauze will answer almost as well, but it is impossible to prevent the ether from coming in direct contact with the face, and there is greater danger of the ether getting into the patient's eyes.

Before starting the anæsthesia foreign bodies were removed from the mouth, all persons that were not absolutely essential were asked to leave the room, and everything made ready for any emergency that might arise. The inhaler was then placed over the face without any ether upon it, and the patient instructed to breathe deeply. In a few moments he became more or less composed, and then the ether was poured on, drop by drop, very slowly at first, gradually increasing the amount as the patient became accustomed to the vapor. At this stage choking and strangling indicated that the anæsthetic was being pushed too rapidly. When relaxation of the upper extremities was obtained the patient was taken to the operating room. The following may be regarded as the most reliable signs of surgical anæsthesia:

1. Deep, regular respirations, often accompanied by snoring, and varying in rate from 10 to 20 per minute. A change in the character of the breathing means usually that more ether is needed, and a long sigh always means the same thing.

2. Absence of sweating, movement of all sign that the patient is sufficiently under the influence of the anæsthetic.

3. The pupils should be moderately contracted and frequently will respond to light slightly during the entire narcosis. In my experience it has never been necessary to have the pupil completely paralyzed.

A sign which is of great importance in this connection is a peculiar jerking or nystagmus of the eyeballs. It may be described as an irregular tremor of both eyeballs that occurs during anæsthesia. Sometimes it is only a rolling of the eyes. It is present if the patient is not too deeply anæsthetized, and is lost when the pupil becomes paralyzed to light. This sign is a very good one to depend upon, both to indicate the degree of anæsthesia and the limit of safety. It was present in every case of this series.

4. Complete muscular relaxation is perhaps the most constant and reliable sign of surgical anæsthesia, the masseter being the last to relax. Occasionally the patient will fail to relax, although every other sign of deep narcosis is present, and more anæsthetic has no effect. If under such circumstances the inhaler is removed and he is allowed to breathe air for a few seconds, and then continue the anæsthetic, relaxation will usually occur promptly.

The average time to produce anæsthesia from chloroform was three minutes, and the average amount required was thirty drops to a drachm. Vomiting after its use was rare, and there was practically no stage of excitement. Chloroform was never used unless there was a special indication for its use, and never routinely, as in the South. The color of the skin and the pulse were considered the best guides to safety.

In a review of the comparative dangers of ether and chloroform, we find that they produce anæsthesia in the same way, but their secondary actions are different and distinct. Chloroform depresses markedly the heart and respiration and lowers blood pressure, while ether has no such effect until the toxic limit is reached. The working limits of chloroform are much less than ether, hence accidents due to an excess of the former are more to be feared, and, moreover, prolonged anæsthesia is better borne with ether than with chloroform.

Lull's statistics showed one death in 2,948 cases of chloroform anæsthesia to one in 13,986 of ether, making ether about five times as safe as chloroform. Fatal terminations from chloroform usually occur suddenly from circulatory failure, but sometimes death does not occur until hours afterward. Autopsy shows a fatty degeneration of all the organs.

Most observers agree, and they are borne out by clinical experience, that ether undoubtedly has many advantages over chloroform which justify the increased favor that it enjoys, and that while chloroform is the more nearly ideal anæsthetic except from the standpoint of safety, it is much more dangerous than ether, and particularly so in the hands of the inexperienced.

In anticipation of trouble, a well matured plan of action should be in mind and everything in readiness to meet any emergency that may arise, for accidents often happen without warning, and delay at this time would be fatal. The anæsthetic should be taken away and the patient given proper stimulation. In my hands the most satisfactory results were obtained with ammonia and oxygen, but others should be used. The difficulty often is that before any active measures can be instituted the patient is in collapse, and there being no arterial pressure, the drugs are not absorbed. Cold to the abdomen and neck, and electricity, may be tried, as may dilation

of the sphincter ani. Tongue forceps and mouth gag are rarely necessary, and the use of the former is not often justifiable, on account of the severe laceration of the tongue which it produces. Turning the head to one side and pushing the jaw forward with the thumbs behind the angles will usually be all that is necessary. Efforts at resuscitation by mechanical means should be tried, but should never be so violent as to cause physical injury. Recent contributions prove that cardiac massage has a most useful field, and one which appears to have been of value mostly in cases of syncope following chloroform anæsthesia. While not having had any experience with it personally, I think that, in a case of last resort and after all other measures have proved ineffectual, massage of the heart should certainly be attempted.

That the life of the patient in many cases rests with the anæsthetizer is a fact not generally appreciated. He should remember that he holds the life of the patient in his hands, and should allow nothing to hurry him, not even an impatient surgeon. All of his thoughts should be concentrated upon his task, but too often he is more interested in the details of the operation than in the anæsthetic.

The administration of the anæsthetic is a task usually relegated to the least experienced resident physician in hospitals, or in private practice to the family physician out of courtesy, often the very person least capable, the reason being that these persons are usually out of experience. To be a good anæsthetist one must give ether or chloroform constantly. The administration of these two drugs is really a specialty in itself, and a successful anæsthetist must be fitted for his task, which can be accomplished in one way only, by experience. He should have sufficient tact and sympathy to give the patient confidence and be able to allay the natural apprehension and fear of the anæsthetic. A careless anæsthetist often allows his patient to come partly out of the influence of the drug, and then crowds it at the command of the surgeon to prevent the complete return of consciousness. The patient is sure to give trouble under such conditions. On the other hand, the skillful etherizer keeps his patient constantly under, and avoids the mouth gag and other troubles, with the result that there is quietness and complete relaxation throughout the entire operation.

Therefore, in conclusion, let me urge that the importance of this subject be given more recognition by medical colleges, and each student receive more individual instruction and experience. Furthermore, let me urge that in hospitals the anæsthetizer be the most experienced man on the interne staff instead of the least experienced.

#### Conclusions.

1. Ether and chloroform are apparently the most satisfactory anæsthetics.
2. Ether is safer than chloroform, but under certain circumstances, when chloroform is desired, the risk may be materially lessened by giving oxygen with it.
3. The average patient was ten minutes becoming anæsthetized and it required two and one half ounces of ether to obtain this condition.

4. The average length of time of the operation was one hour and a quarter, and it required five and one half ounces for this time, or, in other words, about six ounces were used during the first hour, and about three ounces for the second hour.

5. While most of the evidence at hand points in favor of vomiting being due to a centric disturbance in ether anæsthesia, these records show a close relationship between excessive secretion of mucus and vomiting.

6. In the treatment of accidents most dependence may be placed upon ammonia in the form of inhalation, and oxygen.

7. The more remote consequences of anæsthesia, such as status lymphaticus, acetonuria, acidosis, hepatic toxæmia, etc., must not be lost sight of, and general anæsthesia should be preceded by a thorough examination of the heart, lungs, and kidneys.

1013 WASHINGTON STREET.

### PRURITUS ANI.

*Its Cause and Treatment, with Especial Reference to the Use of the Röntgen Rays.*

By R. D. MASON, M. D.,  
Omaha, Neb.,

Professor of Rectal and Pelvic Surgery in the John A. Creighton Medical College; Surgeon to St. Joseph's Hospital

This is the most intractable disease that the rectal surgeon is called upon to treat. It is often spoken of as a trivial matter, yet I have had patients who were almost physical wrecks, due to the loss of sleep, worry, and nervous irritation. I believe that in its early stages it always has some well defined cause which, if searched for and removed, will cure the disease. A little later, however, the terminal nerve filaments become affected, and, even though the cause be removed, or has long since passed away, the itching will still remain.

The skin becomes thickened and parchment like and the nerve endings seem to be pressed upon and constantly irritated. In these cases nothing will give permanent relief except the destruction of this altered tissue and the formation of new skin. There are several ways of doing this, all differing in methods, but aiming at the same end; of course, if there is any cause that is keeping up the irritation, it should be removed. It would be very unwise to try to cure a pruritus due to eczema, pin worms, fistula, hæmorrhoids, rectal catarrh, ulceration, etc., without first removing these.

Dr. Bulls, writing in the *British Medical Journal*, says: "At a recent meeting of the British Medical Association, at Oxford, an interesting discussion took place, in the section on dermatology, on the causation and treatment of pruritus ani; any one reading that debate cannot fail to be impressed with the numerous numbers of distinct diseased conditions to which this annoying symptom was attributed by the various speakers, and, large as the number of supposed causes assigned were, the various plans of treatment advocated were still greater."

This disease is characterized by the most intense itching, which is worse when the patient gets into a warm bed. Patients have told me that pain would

be a relief and would be willingly borne in preference to the pruritus. Many patients do not consult the physician until the disease has become chronic, and it is then most difficult to tell what may have been the cause, as the symptoms may remain, even after the cause has long since passed away.

They will usually try all sorts of remedies before consulting a physician, and when they finally do, the relief is often so transient and unsatisfactory that they drift from one to another with but little benefit from any treatment advised. They are likely to think that but little interest is taken in their case, and go from bad to worse, until, by the time they get into the hands of a rectal specialist, they are often in a serious condition.

In my opinion the disease is caused in the great majority of instances by an unnatural discharge of moisture about the parts; this may be brought about in various ways and by so many different conditions that a most careful search should be made to determine its source before any treatment is started.

As before stated, in chronic cases the cause may have disappeared, or if present its removal may not end the trouble, as the skin has become so thickened and thrown into folds that only its destruction or removal will effect a cure. The irritation that causes the catarrhal discharge may be internal or external hæmorrhoids, chronic proctitis, ulceration, fistulas, especially the small submucous variety with no external opening, pin worms, hard dry fæces which irritates the parts, the lodging of irritating matter in the so called rectal pockets, the growth of small polyps, or in fact anything that will cause an irritation.

Some of the patients who come for treatment are afflicted for the first time, and the cause may be some error of diet, excessive smoking or drinking, and but little treatment is necessary to effect its removal. After many years of study of this disease I have arrived at about the same conclusion as Wallis, of London, who attributes it to a small, shallow ulcer just between the sphincters. He says:

In over ninety per cent. of the cases so examined the shallow ulcer mentioned was found situated, usually between the two sphincters, more often in the posterior half than in the anterior, and generally in the dorsal midline; in some cases there is more than one ulcer, and, again in others there are various clefts which occasionally almost surround the bowel. This ulcer is not easy to recognize by the touch, and it requires a certain amount of practice to appreciate its presence. In the first place, it must be remembered that it is only just within the anal margin, and always below the internal sphincter. The smooth feeling of the healthy lining membrane will be recognized, but when the finger comes onto this abraded or ulcerated surface the smooth feeling disappears, and a slightly raised margin can be felt around the rough surface. There is sometimes pain, but more often none, associated with the examination. When the speculum is introduced, it must be remembered that the tissues are pushed in, some little way, by the instrument, and therefore the ulcer will appear higher up than it really is. If after its introduction the speculum is opened to its fullest extent, the inexperienced observer will probably not recognize the ulcer; but if the speculum is only slightly opened and, when possible, a careful view with a headlight is obtained, the ulcer can be clearly seen as a shallow oval, livid abrasion, differing markedly, and mainly in color, from the normal mucous membrane. Here, then, is a definite lesion, in a so far indefinite disease, and it seemed reasonable to believe that it might be the cause of the irritation.

I have spoken of this little ulcer in my book on

rectal diseases,<sup>1</sup> and further experience only confirms my opinion of its importance. It should be understood, however, that it is not the ulcer itself that itches, but it is the discharge flowing over the parts that causes the trouble. The skin becomes thickened and infiltrated, and loses its vitality. The nerve endings are compressed by the pressure made on them causing an irritation, and itching is the result.

*Symptoms and Diagnosis.*—These are so evident that the patient will have arrived at a diagnosis before consulting the physician. He will probably say that he has "itching piles," as he is unable to recognize the cause of the trouble. His whole thought is how to get rid of the intolerable itching, which is simply wearing his life out.

Upon examination the first thing that will be noticed is that the skin about the anal margin is thrown into folds or ridges, and that it looks unnaturally sodden and dead; also in most cases there will be seen an unusual amount of moisture coming from the bowel above. This roughness and moisture are often the lurking place for dirt and lint from the clothing, which collects here and irritates the parts; even those of cleanly habits are unable to avoid this. An eczema is generally present, often extending over a large area, and the marks of finger nails may be seen, showing the results of scratching. This chronic eczema is very hard to heal, and does not respond to the ordinary remedies used for this disease.

Careful search should be made for some of these conditions which I have mentioned, in order to arrive at some conclusion as to the cause of the trouble. This should in all circumstances be removed, although, as before stated, it may not cure the disease.

*Treatment.*—The most important thing is to find the exciting cause and remove it; this in recent cases will effect a cure. If the skin has become thickened and rough, some method must be adopted to bring it back to as near its normal condition as possible. In some cases this seems to be beyond the reach of drugs, and only to be accomplished by the destruction or removal of the skin. A plan that has given me good results is the application of a ninety-five per cent. solution of carbolic acid to the affected skin; I sometimes use a saturated solution of silver nitrate instead of the acid, as suggested by Adler. The epidermis peels off in a few days, leaving a somewhat tender surface, that should be treated with soothing ointments, such as the ointment of zinc oxide.

After an interval of two or three weeks the acid should be put on again. This may have to be put on several times before the skin becomes natural. Sometimes there are large, warty ridges almost resembling piles. I never waste time with these, but simply cut them off and let the space fill in by granulation. The intervening and all surrounding tissue is treated with the acid.

This seems like rough treatment, and so it is, but it should not be forgotten that we are dealing with a most stubborn disease, and decisive measures must be adopted to bring about a cure. Some patients object, but the majority are willing to submit to anything that promises relief. After all, it is not so

painful, as the acid acts as a local anæsthetic, and, while it burns somewhat, it is a comfort, as it stops the terrible itching.

The following case illustrates the benefits of this method of treatment.

*CASE.*—Mr. W., age forty, treasurer of an eastern Iowa county, and a man of more than ordinary intelligence, came to my office complaining of pruritus that was simply making life unbearable. The disease had troubled him for a long time, but was much worse at present than ever before.

Examination showed the skin to be thick, parchment like, and lifeless, with several heavy folds that radiated from the anal aperture. I explained to him that as he could not remain for treatment, anything that I did must necessarily be quite severe; also that it would have to be kept up at home for a long time. He replied that he "did not care what I put on, as it would be a relief to what he was now suffering. I cut off all the redundant tissue and applied acid to the surrounding skin. I gave him the zinc oxide ointment to use until the soreness had left, and told him to have his wife apply the acid and to keep it up as long as seemed necessary. I also gave him the following injection:

R	Dist. ext. hamamelis, .....	.5x;
	Monsel's solution, .....	.3ij;
	Sodium carbolate, N. F., .....	.3vj;
	Glycerin, .....	.3iv.

M. Sig.: Inject one half teaspoonful in starch water at bedtime.

He was warned against scratching, and told to forego all alcoholic drinks, excessive use of tobacco, rich meats, highly seasoned food, etc. He continued this treatment for a long time and was rewarded with a complete cure. After six years there has been no return of the disease.

In cases that are caused by a vegetable parasite I have made use of pure sulphurous acid with good results. It is generally used in solution, but I have found that it is better to use it full strength. It is quite painful, but one application is all that need be made, as it will destroy any living parasite that may be present.

The application of very hot water, followed by citrine unguentum applied freely on gauze, over which is tightly bound a pad with considerable pressure, will often give relief, so that the sufferer may obtain a good night's rest. In fact, the citrine ointment is the best single agent with which I am familiar to bring about a permanent cure. When used persistently for a long time it will in many instances bring about permanent relief.

It is said that French surgeons use a sharp curette and scrape away all of the diseased skin, thus bringing about the same condition that we do by removing it surgically and bringing the edges together with sutures. The carbolic acid does the same thing, only in a slower manner.

Kelsey uses the white hot cautery, passing it lightly over all the affected parts. This, of course, is only another method of destroying the superficial layer of skin and allowing healthy tissue to take its place. It matters not what may have been the original cause of the disease or how long since this cause may have passed away, there comes a time when the terminal nerve filaments are bound down by the deposit of fibrous matter produced by the irritation of scratching, and nothing short of its complete destruction or removal will bring about a cure.

As before stated, I believe that most of these cases originate from a catarrhal condition of the bowel, and that if seen early enough, treatment directed to this condition, if carefully carried out, would cure the pruritus. Tuttle says:

<sup>1</sup>The Office Treatment of Rectal Diseases, by R. D. Mason.

Catarrhal disease of the rectum and anus are among the most frequent causes; whether it be the atrophic or the hypertrophic form, pruritus is one of the commonest symptoms. The dry, brittle condition of the mucocutaneous membrane about the anus, described as a symptom of pruritus ani, is nothing more or less than a part of the atrophic catarrh of the rectum and anus; and that moist, sodden, whitish condition seen in chronic cases is the result of the hypertrophic type.

It is well known by all who do rectal surgery that after hæmorrhoid operations or any condition where there is a wound that discharges pus as it heals, there is a constant pruritus on all the surrounding tissue owing to its being constantly irritated by the discharge.

Other causes that should be searched for are constitutional diseases, especially diabetes, rheumatism, gout, and all the conditions that go under the name of uricæmia. There seems to be an irritant in the blood that causes cracks and fissures at all the mucocutaneous junctions and pruritus ani and vulvi which are very troublesome.

These people are generally affected with eczema and the skin seems dry and scaly, especially about the scrotum, on the breast, and about the ears and hair.

Certain errors of digestion as well as certain articles of food may start an attack of pruritus. Coffee has seemed to me to be more harmful than any other article of diet, and will alone produce the disease in certain persons. All of these things should be searched for, and, if found, given careful attention. I absolutely refuse to treat a person who is in the habit of drinking any form of alcohol.

As a rule, the treatment must be long and tedious, and unless the patient will make every effort to assist in bringing about a cure I refuse to treat him.

There are many formulæ that are used with more or less success, a few of which are here given. Tuttle speaks highly of the following:

R Ac. carbolic, ..... 3j;  
Ac. salicylic, ..... ʒj;  
Glycerin, ..... ʒj.

M. Sig.: Apply with camel's hair brush after bathing with hot water.

Mathews recommends:

R Camphor and phenol, ..... ʒj;  
Glycerin, ..... ʒj.

M. Sig.: Apply after using hot water, and repeat frequently if necessary.

In cases where there are fissure like cracks at the junction of the skin and mucous membrane, Cripps recommends the following:

R Ext. conii, ..... ʒj;  
Ol. ricini, ..... ʒj;  
Lanolin, ..... ʒj.

M. Sig.: Apply frequently.

An ointment of chloroform as follows acts nicely in many cases:

R Chloroform, ..... ʒj;  
Petrolat., ..... M.

M. Sig.: Apply frequently.

This must be put up in a wide topped bottle and kept tightly corked, as otherwise the chloroform will soon evaporate.

Where the parts are too moist the treatment is often assisted by the use of powders that will absorb the moisture. Plain starch has given good results in many cases. Dry calomel many times is very useful. The following has given good results:

R Camphor, ..... 3ij;  
Carbolic acid, ..... grt. 15;  
Precipitated chalk (Eng.), ..... ʒj;  
Zinc oxide, pulv., ..... ʒj;  
Perfume, q. s.

M. Reduce the camphor with alcohol and mix the others through bolting cloth of one hundred meshes to the inch.

I have operated under chloroform three times by removing a section of the skin for about an inch on each side of the anus, and then undermining the surrounding skin and drawing it together to cover the denuded surface and stitched it to the mucous membrane of the bowel.

In two cases I secured good results, while the third patient was lost sight of. This procedure was suggested to me by my friend, Dr. Hamilton, of this city, and as a means of last resort I believe it to be very valuable. I intend to make further use of it as opportunity arises.

Patients should always be told not to scratch the parts, although this warning is seldom heeded. If the itching is so severe as to interfere with sleep, have them use hot water, gradually increasing the temperature, until it is nearly scalding. In case this is not sufficient to give relief, an ointment of chloroform, one drachm to one ounce of petrolatum, may be applied. A weak solution of carbolic acid in water and glycerin will often give relief when all else fails. The following mixture is a most excellent one:

R Sodium hyposulphate, ..... ʒj;  
Carbolic acid, ..... ʒss;  
Glycerin, ..... ʒj;  
Distilled water, ..... ʒij.

M. Sig.: Apply frequently on compresses.

Also:

R Cocaine, ..... 24 gr.;  
Ex. rhiatany, ..... 15 gr.;  
Ext. hamamelis, ..... 7½ gr.;  
Petrolatum, ..... 3v.

M. Sig.: Apply freely.

Dr. Buckley recommends the following, and I can testify to its merits:

R Ungt. picis, ..... 3ij;  
Ungt. belladonnæ, ..... ʒj;  
Tr. aceton. rad., ..... ʒss;  
Zinci oxid., ..... ʒj;  
Ungt. aque rose, ..... ʒij.

M. Sig.: Apply freely.

I have cured several patients by injecting cocaine under a small portion of the skin where it is thickened and then cauterizing it with the actual cautery. After healing has taken place, another area is treated in the same way. This makes the parts quite sore, but not more than is bearable, and most patients are willing to put up with it if it is likely to cure them.

While the principal attention should be paid to the skin in order to get relief from the itching, yet measures should be taken to cure the catarrh in the bowel above. I have the patient wash out the bowel with solutions of boracic acid and then inject a twenty-five per cent. mixture of glycerite of hydrastis (not fluid extract). Other antiseptic astringent solutions may be used, such as would be beneficial in catarrhal conditions in other parts of the body.

Owing to the difficulty experienced in effecting a cure in some of the chronic cases that have come to me for treatment, and being anxious to try anything that held out any hope of cure I was led to try the Röntgen rays. While my experience has not been

great in the number of patients treated it has been so satisfactory that not only myself but my patients have been delighted with the result.

This method is only useful in old chronic cases where the skin is eczematous and thickened. Just what the action is that brings about a cure I will not attempt to say, but that the eczema disappears and the skin returns to its normal condition or nearly so is beyond question. It is too soon to say positively how permanent the results are going to be, but I think from the appearance of the skin that there will be no return if the bowel above is put in a healthy condition.

My technique is as follows: With a soft tube I give an exposure of ten minutes' duration twice a week, until I learn how the skin is going to stand it. If there is no irritation I give three treatments a week until a brown discoloration appears. All treatment is then stopped until this goes away, when treatment is resumed until it reappears. This is usually enough, but, if possible, I think it is well to give an occasional treatment after this as a matter of precaution.

I hope to make a further report on the use of the Röntgen rays in the near future, after there has been more time to test its merits.

I know of no disease that will so tax the skill and ingenuity of the physician as pruritus ani, and in all cases the patient should be made to understand that in order to be cured he must be willing to do all in his power to aid the treatment. Many times the cure seems to be accomplished when a relapse will occur which is very discouraging to both the patient and physician.

### PRURITUS ANI.

BY CHARLES O. FILES, M. D.,  
Portland, Me.

In the discussion of pruritus ani, in the *Journal* about a year ago, many good and many true things were written, but the final conclusions were peculiarly unsatisfactory to some of the readers of the different communications. When all the customs, habits, and appetites supposed to be inimical to general health are given as direct causes of this simple, yet exasperating, malady, the real, immediate cause seems buried beyond hope of recovery or resurrection.

Constipation, from whatever source, is surely an accessory or antecedent cause of this trouble. It is possible, however, to come much nearer to the immediate or exciting cause, if we investigate more closely. There are two important factors which ought to be studied. These are an analysis of the contents of the rectum, and the physical condition and mechanical efficiency of the sphincter ani muscles, external and internal. The normal feces contain about seventy-three per cent. of water. This water holds in solution various volatile, fatty acids and probably other irritating excrementitious substances. During the retention of the feces in the rectum a considerable portion of the water disappears. In prolonged constipation the feces become hard and dry. Some of this fluid passes by osmosis into the cellular tissues about the anus, and thence

to the skin. The liquid feces are often very irritating to the mucous membrane of the anus, and cause an intense burning sensation. When this acid, acrid solution is absorbed into the cellular tissues it causes an irritation of the skin, and we call that irritation pruritus ani. The sphincter muscle, as long as it remains in a normal condition, prevents the passage of any appreciable amount of fluid through it. When, however, it is made somewhat irregular by the presence of a hemorrhoidal condition, some of the fluid leaks through the sphincter and causes the pruritus by direct contact. The skin about the anus is often found to be moist in persons having hemorrhoids.

The treatment of this affection may be easily deduced from this statement of its causes. The patient should be directed to take only those kinds of food that are easily digested, that are not constipating, and that are not irritating. The bowels must be kept open by the use of saline cathartics. Locally, any soothing applications will allay the irritation temporarily. Castile soap, boric acid, cold cream will serve as well as anything.

### Correspondence.

#### LETTER FROM HAMILTON, CANADA.

*The Ontario Medical Association.—Infanticide.—Teaching in Psychiatry.*

HAMILTON, June 1, 1908.

The Ontario Medical Association met here on the 26th, 27th, and 28th of May, under the presidency of Dr. Ingersoll Olmstead, of Hamilton. It was the largest meeting of the association ever held, the attendance amounting to 317. From the standpoint of scientific matter produced, it was about the best. Dr. Charles G. Stockton, of the University of Buffalo, delivered the address in medicine, and Dr. Charles Scudder, of Boston, the address in surgery. Several members of the profession in Montreal were present and contributed to the papers and discussions. Speaking at the annual banquet, on the evening of the 27th, Dr. Roddick, of Montreal, strongly urged that interprovincial legislation be secured and that the barriers keeping doctors in the different provinces from practising their profession in an adjoining province be taken down. He believed that the government of the medical profession should be in the hands of the Federal Government, and that it was intended so by the British North America Act. It was the opinion of Dr. Roddick that as soon as Ontario strongly urged this measure other provinces would soon fall into line.

The meeting unanimously adopted the following resolution: "That, whereas the destruction of children for any other cause than that of the preservation of the life of the mother; and whereas the perpetration of this act by a member of the medical profession not only incriminates the physician himself, but also brings discredit on an honorable profession, we, members of the Ontario Medical Association, take this opportunity of stating that the association has always condemned in the strongest possible terms this criminal practice."

Another resolution passed read as follows: "That the Ontario Medical Association desires to give ex-

pression to its hearty approval of the proposition of the Ontario government to establish psychiatric clinics to work in conjunction with the hospitals for the insane of the province; that the association also respectfully request the government to have a lunacy commission or a board of alienists, who alone shall give expert evidence in a court of law as to the sanity or insanity, and also to institute reforms in the civil service, in connection with the hospitals for the insane, whereby promotion for merit shall take place, and especially to make a rule that no one shall be appointed superintendent of any hospital for the insane unless he has had some years of training in the service."

It was decided to meet in Toronto next year with the following officers: President, Dr. H. J. Hamilton, of Toronto; vice-presidents, Dr. R. R. Wallace, of Hamilton; Dr. A. M. McFaul, of Collingwood; Dr. A. Dalton Smith, of Mitchell; and Dr. George H. Field, of Coburg; general secretary, Dr. E. Stanley Ryerson, of Toronto; assistant secretary, Dr. J. E. Davey, of Hamilton; treasurer, Dr. J. H. Mullin, of Hamilton.

#### LETTER FROM TORONTO.

*The University of Toronto and the Toronto General Hospital.*

Toronto, May 30, 1908.

A pamphlet entitled *The General Hospital versus University of Toronto*, embracing a series of articles dealing with the supposed unfair action of the board of governors of the Toronto General Hospital, in their recent reorganization of their staff scheme, toward the Medical Department of the university, has been freely distributed among the medical profession in this city, and probably to some extent among the public at large. These articles have been appearing regularly for a month past in one of Toronto's evening papers. As the stand is taken by some one favorable to the university, and probably by some one whose ox has been gored, your correspondent has taken the liberty of placing the University of Toronto in the position of plaintiff and the Toronto General Hospital in that of defendant. The complaint is made that in the recent reorganization of the staff of the hospital the understanding on which the university contributed \$300,000 toward the erection of a new hospital, designated as the most important factor in the new scheme, was that, so far as possible and practicable, the hospital was to be made a university hospital, and that that understanding had been totally disregarded by the board of governors of the hospital in making these appointments. The charge is made that the hospital authorities did not intend to and did not recognize the university in the working out of their plans for reorganization, and do not propose to do so. To those who have read these letters and have carefully perused the pamphlet, it is difficult to understand wherein any very strong "kick" can emanate from any member of the Medical Department of the University of Toronto. As a matter of fact, the heads of all the departments or services in the hospital, as well as all their assistants except two, are members of the Medical Department, and there are mighty few of the juniors under these but all are associated with the Medical Department of the university as teachers, demonstrators, or pathologists.

Looking at the matter altogether apart from the standpoint of medical education, and just from its financial aspect and the point of view of the medical practitioner in Toronto at large, it would appear that the Toronto General Hospital is, practically speaking, a university hospital. Not a single practitioner from outside the Medical Department of the university received an appointment as head of any service in the hospital, and only two of the senior assistants are beyond the pale of the Medical Department of the university. The University of Toronto contributed \$300,000 toward this proposed new hospital; the city of Toronto, \$200,000; subscribers, \$700,000; and the old hospital board handed over a million dollars of assets. It will strike most people that the University of Toronto for its donation of \$300,000 has done exceedingly well in the matter of appointments. If one cared to carry the matter further, the questions might be asked, Where were the five representatives of the city of Toronto on the board of governors of the hospital? Where were the seven representatives on that board of the subscribers?—Yes, where were the eight representatives of the Province of Ontario on that board when the scheme was going through? Did the five representatives of the university on the board, which represented a \$300,000 donation, "jockey" the others? In the face of these palpable facts, one of the board of governors in his reply to these newspaper articles states it is not a university hospital—"the university is but one of several parties in its welfare." The "one of several parties" seems to have done pretty well.

It has been admitted by one of the board of governors of the hospital that, had that institution been made a university hospital out and out, some of the subscribers of the \$700,000 would not have come forward with their checks. This looks very much like an admission of fear of financial loss, on the one hand, but a latent feeling that it should have been a university hospital, on the other. It is doubtful if, provided the hospital had been made a university hospital pure and simple, very much of this \$700,000 would have been lost to the institution; it is doubtful if there would have been very much objection to making it such. It would have been far better in many ways if the five representatives of the university had carried the day outright, rather than have the one sided arrangement as at present.

#### Therapeutical Notes.

**Iodine in the Treatment of Ulcers.**—In a communication to the *Journal of the American Medical Association* for May 30, 1908, J. W. Rupp, of Apache, Okla., says he has found the application of a saturated solution of iodine in alcohol to give excellent results in the treatment of ulcers. He began by painting the skin up to the edge of the ulcer, and this produced such good results that he continued to use it on the surface of the ulcer itself. He has found that iodine used in this way is an efficient means of converting a septic ulcer into a clean, granulating wound which heals readily. He applies the iodine either in a concentrated form or a saturated solution, and that he uses it in various

as is required until the slough separates, when an ordinary dusting powder and gauze may be applied. The iodine should then be discontinued, but if any unhealthy or superfluous granulations appear, it should be again applied. He says it quickly changes a phagedenic ulceration into a healthy condition, and speaks of other indications in which it has been serviceable, as in mouth and throat troubles, by painting it over the surface. It will arrest and cure pyorrhœa alveolaris. The application is usually painless.

**Treatment of Severe Burns.**—Having had occasion to treat extensive burns on workmen in the sugar works, glass factories, and mines in the district of Douai, Dr. Galand, of Cambrai, recommends the use of the following paint, which is applied with a camel's hair pencil over the entire surface of the injured parts. The application produces a sensation of coolness and relieves the pain, forming at the same time a varnish coating which serves to replace the denuded skin (*Bulletin général de thérapeutique*, May 8, 1908):

R	Carbolic acid, .....	gtt. xxv;
	Pulverized dextrin, .....	℥iv;
	Tincture of aloes, .....	℥iii;
	Spirit of camphor, .....	℥i;
	Lead nitrate, .....	gr. xlv;
	Tannic acid, .....	gr. xv;
	Cherry laurel water, .....	℥v.

M.

To make a perfectly homogeneous mixture it is necessary to have the dextrin in a state of impalpably fine powder. To this is added little by little the mixture of tincture of aloes and spirit of camphor, rubbing up until thoroughly incorporated. The cherry laurel water containing the lead nitrate and tannic and carbolic acid is then added.

Apply with a brush, and after the first coating has dried apply a second or third coating to the more severely injured parts.

**Adrenalin in Acute Eczema.**—According to N. E. Aronstam (*Central States Medical Monitor*) a solution of the active principle of the suprarenal gland is astringent and soothing in acute eczematous conditions and dermatitis. He recommends its use in the following combination:

R	Boric acid, .....	gr. v;
	Solution of adrenalin (1 in 1000), .....	℥i;
	Camphor water, .....	℥iii;
	Distilled water, .....	ad ℥i.

M.

A piece of sterile gauze is saturated with the solution and applied to the inflamed or affected parts, the application being renewed when the dressing is dry.

**Treatment of Mushroom Poisoning.**—Maheu, in *La clinique*, summarizes the treatment of mushroom poisoning. The first thing to do is to evacuate the stomach by an emetic and then administer a purgative. In cases where there is contraction of the jaw, apomorphine should be given hypodermatically in a dose of one twelfth of a grain for adults. After the stomach has been emptied of the poisonous matter, administer demulcent drinks, such as milk, albumen water, etc. Apply a sedative application of camphorated liniment and chloroform to the

abdomen; to overcome the fainting condition sinapisms may be applied, or hot coffee given internally, or hypodermatic injections of ether, or caffeine.

**The Treatment of Earache.**—Earache of the most intense variety is generally caused by the formation of a furuncle in the auditory passage. The treatment should consist, according to Molinié (*Journal de médecine et de chirurgie pratiques*, March, 1908), of overcoming the pain and evacuating the boil. The parts should be made strictly aseptic, and after cleaning them minutely, the painful spot should be touched with the following solution, applied with a plectet of cotton:

R	Cocaine hydrochloride, .....	
	Carbolic acid, .....	
	Menthol, .....	ââ gr. xv.

M.

This application will deaden the pain and sometimes abort the furuncle. If the inflammation persists the boil should be opened under an anæsthetic, either local or general. Otitis of the middle ear, which causes a most violent pain, is treated either by palliative means or by operation. As a means of relieving the pain the following solution may be employed by dropping a few drops of it warmed into the ear:

R	Cocaine hydrochloride, .....	gr. xii;
	Morphine hydrochloride, .....	gr. iv;
	Carbolic acid, .....	gr. iiss;
	Glycerin, .....	
	Water, .....	ââ gr. lxxv;
	Spirit of peppermint, .....	gtt. i.

M.

**Applications in Galactorrhœa.**—The application of a solution of cocaine hydrochloride is recommended by Dr. Comby and by Dr. Joire; the formula used by the first named is as follows, according to *Journal de médecine de Paris* for May 9, 1908:

R	Cocaine hydrochloride, .....	gr. iii;
	Distilled water, .....	℥iiss.

M.

Dr. Joire's prescription is:

R	Cocaine hydrochloride, .....	gr. lxxv;
	Glycerin, .....	℥iiss;
	Distilled water, .....	℥iiss.

M.

The mammæ and areolæ are painted with the solution by means of a camel's hair pencil, or with a wad of absorbent cotton. The efficacy of cocaine in this application is due to its vasoconstrictive action.

**Injection for Internal Hæmorrhage.**—Huchard prescribes the following for hypodermatic use in internal hæmorrhage:

R	Ergotin, .....	gr. 1/7;
	Lactic acid, .....	gr. 1/3;
	Cherry laurel water, .....	℥iiss.

M.

**A Liniment for Engorged Lymphatic Glands.**—Heindl, of Vienna, treats engorged lymphatic glands by the alternate application of compresses wet with solution of aluminum acetate and rubbing with the following liniment:

R	Veratrine, .....	gr. viiss;
	Chloroform, .....	℥i;
	Oleobalsamic mustard, N. F., .....	℥iii.

M.

NEW YORK, SATURDAY, JUNE 13, 1908

## THE NEW PRESIDENT OF THE AMERICAN MEDICAL ASSOCIATION.

We congratulate the association on its choice of Colonel William C. Gorgas, of the Medical Corps of the United States Army, of whom we present a portrait in this issue, as its next president. Colonel Gorgas's achievements in sanitation have won for him the admiration of the nation, and his personal qualities have endeared him to those whose privilege it has ever been to come within the gentle charm of his presence. He did not need strengthening before the public by any such specific support as is proclaimed by his election to the presidency of the great representative association of the medical profession of the country, but it was none the less a most graceful act for the association to signify its appreciation of the man and of his services by making him its chief officer.

The Medical Corps of the United States Army, the Bureau of Medicine and Surgery of the United States Navy, and the United States Public Health and Marine Hospital Service are organizations of which the medical profession is proud, and we hope that it will often take occasion to signify its pride in them by designating their members as chiefs among its representatives. Though it is but a few years ago that Surgeon General Sternberg, of the army, was the president of the American Medical Association, it was high time for the association to attest anew its appreciation of the various medical corps of the national service. Not only has their service training a decided tendency to fit the members of those corps for the duties and responsibili-

ties of a presiding officer, but their purely professional attainments entitle them to the highest recognition. We predict for Colonel Gorgas a memorable record as president of the American Medical Association.

## ALUMNI REUNIONS IN CHICAGO.

The difficulty of assembling alumni resident in all parts of a country so large as ours is ordinarily very great, but it was to a large extent overcome in Chicago last week. It is true that the Chicago meeting of the American Medical Association was large beyond precedent and, we imagine, beyond all expectation, for more than six thousand members were registered, and there was the usual attendance, perhaps more, of visiting physicians who were not registered. It was this influx, of course, that brought with it a vast number of persons inclined to take part in alumni reunions; but any annual meeting of the association, even one not half so large as that of Chicago, may be counted upon to bring together more alumni of an individual medical school than could well be gathered together on a different occasion. Several of the school organizations took advantage of the certainty that the great meeting would enable them to assemble their members in multitudes, and consequently their reunions, all held on one evening, were numerically much superior to the common run of such gatherings. The element of entertainment was in the ascendant, very properly, and banquets, smoking concerts, and the like made the assemblies festive as well as promotive of college spirit.

It must be confessed that our Western friends manage such a thing as a large banquet much better than we of the East generally do it. There is an initial heartiness about them that makes a stranger feel at home at once, and joy does not lag until the wine has begun to work. In the Atlantic States it is too apt to be the case that a man of little or no prominence arrives on the scene of a dinner with nobody particularly disposed to beguile for him the wearisome waiting period. Joviality and community of feeling do, indeed, come at last, but, like the flavor of the persimmon, not until after a frost has been encountered. It was the privilege of a representative of this journal to be seated in the lobby of the Illinois Athletic Club while the alumni of the Medical Department of the Northwestern University were gathering for their banquet, and he could not help admiring the conduct displayed. For the time being, he regretted that he himself was not a Northwestern alumnus. An energetic and hearty reception committee stood at the doorway of the great building; its members were not seated in solemn and frigid dignity in a room more or less difficult to

find and ready to play the snob when at last they were found. No sooner had a man stepped inside than he was cordially grasped by the hand and, in case he was not personally known to any member of the committee, asked if he had come to join in the banquet. On his answering in the affirmative, he was led (not directed) to the place where he could divest himself of his hat and overcoat, and from that moment the fraternal feeling had full play. One could not but admire, also, the skill with which the great throng was handled; 789 men arrived to attend the banquet, about 250 more than had been expected, but the excess worked no serious inconvenience, such was the capability of the club's manager, and with an insignificant minimum of waiting, spent in kindly frivolity of speech, everybody was comfortably seated. Surely the management of a banquet is among the many things in which we might to our advantage take lessons of our Western friends.

#### PALMAR PROJECTION OF THE ULNA AFTER COLLES'S FRACTURE.

In the May number of the *Providence Medical Journal*, Dr. Franklin C. Clark, of Providence, presents a practical and very interesting subject for consideration, that of a projection of the lower end of the ulna "forward" (toward the palmar aspect of the wrist) after Colles's fracture, manifesting itself secondarily, i. e., coming on at a comparatively late period, after the fragments of the radius have united. The occurrence seems to be rather rare, as Dr. Clark has met with only two instances of it in a practice of over thirty years. He gives the histories of these cases. In one of them he might have been inclined to attribute the abnormality to the very extensive injury to the parts sustained by a woman, forty years old, in a backward fall down the entire length of a flight of stairs of seventeen steps. In the other case, however, the injury seems to have been caused by a simple fall forward, the weight of the patient, a woman of sixty, coming upon the palm of the hand.

This complication appears to detract decidedly from the utility of the wrist joint, no matter in what perfect apposition the fragments of the radius may have united, and it is apt to lead to a conviction on the part of the patient that the fracture was improperly set in the beginning. It occurs in cases treated exactly like other cases of Colles's fracture in which the ultimate result is in every way satisfactory. Dr. Clark lost sight of both his patients soon after the complication had been recognized, apparently without his having advised any secondary treatment, and it is difficult, indeed, to see that

much benefit could be derived from any treatment beyond the support that might be given by a band. Dr. Clark thinks that this untoward sequel of Colles's fracture has not received enough attention at the hands of surgical authors, though he finds material more or less bearing upon it in the writings of the late Dr. Frank H. Hamilton, the late Dr. E. M. Moore, Dr. John B. Roberts, Dr. F. J. Bowen, and Dr. Vertner Kenerson.

#### PSYCHIATRY AS A PART OF PREVENTIVE MEDICINE.

At the recent meeting of the American Medico-psychological Association, held in Cincinnati, Dr. Henry M. Hurd, of Baltimore, read a paper with this title. Coming, as it did, shortly after the president's address, in which the relation of psychiatry to preventive medicine was also discussed, it was most timely. It is only necessary to look back over the history of mental medicine in this country for the past quarter of a century to appreciate the many changes which have occurred in the methods of caring for and treating the insane. Housing facilities and means of recreation and employment have been improved and multiplied, while the profession has had placed at its disposal many therapeutic agents which were before unheard of. When, however, we look at the results, to see what effect all this activity has had, we are chagrined to find that apparently there has been hardly an adequate return for the energy put forth.

Dr. Hurd, therefore, felt impelled to speak of psychiatry in the rôle of preventive medicine, as it is in this direction that he feels that we must labor in the future if we are to accomplish aught to stem the tide of mental disorder. He properly laid special stress upon supervision of the life of the child, with a view to detecting the earliest appearance of abnormal mental tendencies, so that the individual could be put right before it was too late. Our schools employ physicians to look after the eyes, the ears, the noses, and the chests of the children, and surely it is equally if not more important that their mental condition should be studied with a view, not only of detecting the earliest signs of abnormality, but also of preventing the stress of school life and prescribing, to some extent at least, the character of the studies best suited to the individual.

Dr. Hurd's paper was very favorably received and freely discussed. A significant feature of the discussion was the remarks of Dr. William A. White, of Washington, who sounded a note that rings true when he said that the association, instead of meeting year after year and dining together and exchanging the compliments of the season, ought

to rise to the great public issues, such as those discussed in Dr. Hurd's paper, and express itself as an organization composed of the representative men of the country engaged in the practice of mental medicine. We fully agree with Dr. White in this particular. The profession of the country has always had the profoundest respect for their confrères of the Medicopsychological Association, and to attain even a higher position they have only to rise to the fuller measure of their responsibilities in advancing as a body the domain of psychiatry in its preventive aspects. No single class of specialists is so well fitted for the work; we believe that they will not lack the energy to accomplish it.

### WHAT IS HYSTERIA?

The "pain child of neurology" is the apt name given to hysteria by Binswanger in his recent monumental monograph. Wrapped in swaddling clothes, hidden in the disjointed fragments of other disorders of body and mind, it was reserved for the all seeing eye of Charcot to discover that in this mass there were those whose paralysis was not like that due to a lesion of the brain, of the fibre tracts of the cord, or of the peripheral nerves—those whose disturbances of sensation did not agree with the picture seen resulting from a disorder of the sensory nerves of the periphery, of the spinal cord, or of the brain, and looking through the new lens of hypnosis he read an answer to the riddle which, from the days of the Greeks to the present time, has demanded an explanation and been given thousands.

Charcot's answer to the question was that "hysterical are those physical and mental processes of extraordinary character and strength which may be brought into being by ideas." Many noted neurologists have been content with this general conception, Möbius accepting it bodily; while in more recent times Babinski has extended the idea, and indicates that "hysteria is a special psychic state manifesting itself principally in disturbances which may be called primary and subsequently in secondary disturbances." The primary disturbances are distinguished by the fact that it is possible to reproduce them by suggestion in certain cases with rigorous exactitude, and to cause them to disappear under the exclusive influence of persuasion. The secondary disturbances are distinguished by the fact that they are immediately subordinate to the primary disturbances.

Babinski lays a heavy weight of responsibility on the physician, and by implication would make him responsible for much that he himself would try to treat. How much stomach washing, bowel cleansing, massage, and electricity have done to perpet-

uate the maladies sought to be alleviated thereby will never be known, and the different outlook of alienist and neurologist will continue to breed dissension between brothers in the same profession, with similar therapeutic desires, so long as they see these features from such diverse viewpoints.

The views of Janet, of Vogt, and of Breur and Freud, expressed with much subtlety of analysis and wealth of metaphor, are but finer architectural stylistic efforts reared on the foundations and fashioned after the lines of the ground plan laid down by Charcot. When Janet postulates the cause of hysteria as a splitting of certain elements of consciousness from the consciousness of self—the personality—thus giving rise to a sleeping, somnambulistic self alongside of the ego; and Sollier postulates a local sleep area; and Vogt assumes a dissociated condition, giving rise to a localized sleepy retardation on the basis of a pathologically increased affectivity, they all assume the essential relation of the phenomena of hypnosis to hysteria, just as Forel's phrase "increased autosuggestibility" or Möbius's "pathologically increased suggestibility" points out that in hypnosis we have an artificial production of what takes place in hysteria naturally. The hypnotized person realizes the relation of an outside influence, the hysterical the will of an unknown ego, which unknown, unconscious, and hidden ego, according to the narrower conceptions of Breur and Freud, has arisen in times long gone by, in childhood, on the basis of sexual experiences, but lying dormant, so far as consciousness is concerned, is still able to bring forth action sufficient in intensity to modify the conscious personality.

Dubois, Schnyder, and Hellpach, attacking the problem from the genetic point of view, see in hysteria types of reaction to environmental factors which Hellpach has developed along the psychological path. Experience has taught that, whereas a large number of individuals grow out of or adjust themselves completely to a number of disturbing causes in their environment, or, if reacting abnormally for a time, later reach a satisfactory adjustment, still a number do not, and in this latter group he sees two classes with what he calls "a reactive and a productive abnormality." The latter proceed to the formation of frank mental diseases; the product is a definite failure of adjustment, as in dementia præcox, paranoid dementia, paranoia, etc. The former make up a group of unstable, labile individuals of lessened resistance to external stimuli. In this group are to be found the individuals of the hysterical reaction type. This is the fundamental rudiment. It is the generalized mentality of a former age, through which man has developed. The hysteria of the masses of the Middle Ages has passed

Its modern descendants for the masses are the psychoneuroses. Atavisms there are in plenty, hysteria in children of either sex in about equal proportions; hysteria in adult women more than in adult men; in men hysteria being more common among the lower and undeveloped classes, but generalized hysterical reactions only here and there in certain religious sects that recruit their members from such atavistic individual reaction types, or under certain paralyzing emotional stresses that reduce the tension in the mass to the low water mark of preceding generations.

In Helpach's view we see a healthy breaking away from the mysteries of the "unconscious," the "subconscious." How can a disorder involving psychical factors be understood in the mystifying phrases of "unconsciousness"? How will such psychical processes be analyzed if lost in the mysterious gray substance of mind? That the way opened by him will be productive of light we feel assured; but that the problem is solved is a premature belief.

### News Items.

**Changes of Address.**—Dr. Charles S. James, to 624 Lexington Avenue, New York, where he will resume practice.

**The Inauguration of Columbus Hospital, Buffalo, N. Y.,** took place on Sunday afternoon, June 7th.

**The First Spanish Congress on Tuberculosis** will be held in Zaragoza, Spain, on October 2d to 6th, 1908.

**The Croonian Lectures** will be delivered at the Royal College of Physicians of London on June 18th to 30th, by Dr. A. E. Garrod on Inborn Errors in Metabolism.

**The Commencement Exercises of the Maryland Medical College** were held on the evening of June 2d. Twenty young men received the degree of doctor of medicine.

**Donation to the St. Louis Skin and Cancer Hospital.**—It is announced that a gift of \$100,000 in cash and the site for a new building has been made to this institution. The donor's name is withheld.

**Personal.**—Dr. Isadore Dyer has been appointed dean of the Medical Department of Tulane University, to succeed Dr. Chaillé, who recently resigned. It is said that Dr. Dyer is the youngest dean in America.

**Richmond, Va., Academy of Medicine and Surgery.**—At a meeting of this academy which was held on Tuesday, June 9th, Dr. C. M. Hazen read a paper on Electrotherapeutics, and papers on Cataphoresis were read by Dr. M. W. Peyser and Dr. F. K. T. Warwick.

**The Northwestern Medical Association of Philadelphia.**—At a stated meeting of this society, held on Friday evening, June 12th, Dr. William Egbert Robertson read a paper on the Diagnosis and Treatment of Diseases of the Heart, which was illustrated with lantern slide pictures.

**Buffalo Academy of Medicine.**—The annual meeting of this academy was held on Tuesday evening, June 9th. Officers for the ensuing year were elected, and reports were presented of the commissions on milk supply, on food supply, on inspection of schools and school children, and on smoke and noise nuisance.

**St. Gregory's Hospital, New York.**—At a special meeting of the board of directors of this hospital, which was held on June 2d, Mr. John W. Thomas, of New York, was elected treasurer. Owing to the enforced absence of the superintendent, on account of illness, Mr. Thomas is at present acting superintendent of the institution.

**The Medical Club of Philadelphia** held a reception at the Bellevue-Stratford Hotel on the evening of June 12th. Dr. William L. Estes, of South Bethlehem, Pa., president of the Medical Society of the State of Pennsylvania, and Dr. Albert M. Eaton, of Philadelphia, president of the Philadelphia County Medical Society, were the guests of honor.

**Franklin District, Mass., Medical Society.**—At the annual meeting of this organization, which was held in Springfield recently, the old officers were reelected without change, as follows: President, Dr. J. W. Cram, of Colrain; vice president, Dr. C. L. Upton, of Shelburne Falls; secretary and treasurer, Dr. Clara M. Greenough, of Greenfield.

**Women Nurses in French Military Hospitals.**—It is reported that women nurses are to be given a trial in the military hospitals in France. The hospital connected with the military medical school at Val-de-Grace, near Paris, has made the experiment, and if it proves to be successful other military hospitals will be supplied with women nurses.

**Medical Society of the County of Richmond, N. Y.**—At the regular monthly meeting of this society, which was held in the Staten Island Academy of Medicine on the evening of June 10th, Dr. Walker Washington read a paper entitled *The Differential Diagnosis of Typhoid Fever*. The discussion was opened by Dr. A. T. Wood and Dr. H. Patterson.

**The Medical Society of the Borough of the Bronx.**—A stated meeting of this society was held on the evening of Wednesday, June 10th. The meeting was largely clinical, the evening being devoted principally to the presentation of patients and the reports of interesting and unusual cases. The paper of the evening was read by Dr. Charles Herrman on *Scarlet Fever Carriers*.

**A Research Fellowship at George Washington University.**—The graduating class of the Department of Medicine of George Washington University have announced to the university authorities the establishment by the class of a research fellowship at the university. The fellowship will be known as the Class of '08 Fellowship, and will have an annual fund of not less than \$300.

**Contagious Diseases in Chicago.**—During the week ending May 23, 1908, there were reported to the Department of Health 660 cases of contagious diseases, an increase of 107 over the preceding week. Of the total number 353 were of measles; 88 of scarlet fever; 70 of diphtheria; 57 of tuberculosis; 39 of chickenpox; 23 of whooping cough; 20 of typhoid fever; 1 of smallpox; and 9 of less important diseases.

**Connecticut State Medical Society.**—At the one hundred and sixteenth annual meeting of this society, which was held in New Haven recently, the following officers were elected for the ensuing year: President, Dr. Selden B. Overlook, of Pomfret; first vice president, Dr. Irving L. Hamant, of Norfolk; second vice president, Dr. W. L. Barber, of Waterbury; secretary, Dr. W. R. Steiner, of Hartford; and treasurer, Dr. Joseph H. Townsend, of New Haven.

**American Association of Medical Examiners.**—The ninth annual meeting of this association was held in Chicago during the week of the meeting of the American Medical Association. Officers for the ensuing year were elected as follows: President, Dr. Frank E. Allard, of Boston; vice presidents, Dr. L. H. Montgomery, of Chicago, Dr. Allison Maxwell, of Indianapolis, Ind., Dr. W. J. Means, of Columbus, Ohio, and Dr. E. O. Kinne, of Syracuse, N. Y.; secretary and treasurer, Dr. J. G. Monihan of New York.

**American Association for the Advancement of Science.**—A special summer meeting of this association will be held in the buildings of Dartmouth College, Hanover, N. H., on June 29th to July 3d. Information relating to the presentation of papers may be obtained from the secretary, Mr. L. O. Howard, Smithsonian Institution, Washington, D. C., and information on matters relating to local arrangements may be obtained from Professor H. H. Horne, Dartmouth College, Hanover, N. H.

**The Mortality of New Jersey.**—During the month ending May 15, 1908, there were reported to the Bureau of Vital Statistics of the State of New Jersey 2,602 deaths from all causes, a decrease of 532 from the preceding month, and a decrease of 386 from the corresponding period in 1907. The causes of death were: Typhoid fever, 28; measles, 27; scarlet fever, 46; whooping cough, 23; diphtheria, 11; malarial fever, 3; tuberculosis of the lungs,

**Vital Statistics of New York.**—During the week ending May 30, 1908, there were reported to the Department of Health 1,335 deaths from all causes, in an estimated population of 4,422,685, corresponding to an annual death rate of 15.75 in 1,000 of population. Of the total number of deaths 693 were in Manhattan, 123 in the Bronx, 437 in Brooklyn, 56 in Queens, and 26 in Richmond. The total infant mortality was 350; 270 under one year of age, and 80 between one and two years of age. There were 124 still births. Three hundred and sixty-three marriages and 1,879 births were recorded during the week.

**Ferryboats as Open Air Hospitals for the Tuberculous.** Bellevue Hospital has acquired the old Staten Island ferryboat *Southfield* and turned it into an open air hospital for incipient cases of tuberculosis. The value of this work was demonstrated by the Charity Organization Society, who used the *Southfield* for a similar purpose last year. The boat, which has been entirely refitted, is under the supervision of Dr. James A. Miller, chief of the tuberculosis clinic of Bellevue Hospital. It was placed in commission and formally opened for patients on June 3d. It is said that Gouverneur Hospital and the Presbyterian Hospital have obtained old ferryboats, which will be properly equipped and used as open air hospitals for tuberculosis patients.

**The American Hospital Association.**—The tenth annual conference of this association will be held in Toronto on September 22d to 25th. The purpose of this organization is the promotion of economy and efficiency in hospital management. It has a total membership of four hundred, which includes more than a hundred hospitals not previously identified with the association, and it is anticipated that the gathering of hospital workers in Toronto will be unprecedented in number, character, and enthusiasm. The programme will include papers on the varied interests of hospitals, large and small, not only by members of the association, but by guests who have been invited to participate in the meeting on account of their peculiar fitness for dealing with some phase of the problem of hospital management.

**Medical Society of the County of Kings, N. Y.**—The first clinical meeting of the Section in Pediatrics was held on Friday afternoon, June 12th. The programme included a symposium on heart disease in children, patients being exhibited by Dr. Archibald D. Smith, Dr. L. C. Ager, Dr. F. B. Van Wart, Dr. Le Grand Kerr, Dr. Alexander Spingarn, and Dr. Lester W. Volk. The following reports of cases were presented: A case of sporadic cretinism, by Dr. George F. Little; cases illustrating the late deformities of acute anterior poliomyelitis, by Dr. F. B. Cross; a case of transposition of the viscera, by Dr. L. C. Ager; a case of cerebellar tumor, and a case of tuberculous dacrylitis, by Dr. Archibald D. Smith; two cases of hereditary spinal spastic paraplegia, by Dr. Alexander Spingarn; a case of hemiplegia, and a case of pituitary tumor, by Dr. F. B. Van Wart. Dr. Archibald D. Smith is the chairman of the section, Dr. John W. Parrish is vice chairman, and Dr. William H. Woglom is secretary and treasurer.

**The Medical Society of New Jersey.**—The one hundred and forty-second annual meeting of this society will be held at the Hotel Cape May, Cape May City, on June 18th, 19th, and 20th. The first session of the house of delegates will be held at the hotel at 10:30 a. m., Thursday, when the reports of the various committees will be presented. The first general session will be opened on Thursday afternoon with the oration in medicine by Dr. William K. Newton, of Paterson. The last general session will be held on Saturday morning. The annual banquet will be held on Friday evening, Dr. Stephen Pierson, of Morristown; Dr. Hobart A. Hare, of Philadelphia, and the Hon. Joseph S. Frelinghuysen, of Raritan, being among the speakers. The officers of the society are: Dr. Edward J. Ill, of Newark, president; Dr. David St. John, of Hackensack, Dr. Benjamin A. Waddington, of Salem, and Dr. Thomas H. MacKenzie, of Trenton, vice presidents; Dr. William J. Chandler, of South Orange, recording secretary; Dr. Daniel Strock, of Camden, corresponding secretary; and Dr. Archibald Mercer, of Newark, treasurer.

**Bombay Medical Congress.**—A medical congress will be held in Bombay in February, 1909, under the presidency of His Excellency the Governor of Bombay. The Central Committee, which is composed of representatives of the different branches of the medical profession, official and unofficial, invites original contributions from prominent authorities on subjects relating to tropical medicine and sanitation as applied to India, and is also prepared to consider voluntary communications from any one desirous of contributing. There will be an exhibition of pathological and microscopical specimens of medical, surgical, and sanitary appliances, and a series of lantern slide demonstrations. The sessions will extend over four days, and the subjects will be considered in six sections as follows: Section I—Cholera, dysentery, enteric fever, and tropical diarrhoea. Section II—Malarial fever, Plague, Leishman-Donovan body invasion, and relapsing fever. Section III—Parasitic insects, snake venom, beriberi, mycetoma, elephantiasis, and leprosy. Section IV—Systems of disposal of sewage in India, water supplies, (measures necessary to ensure purity, etc.), disinfection (methods applicable to India houses, including methods of destroying vermin), and miscellaneous papers on general sanitation. Section V—Ophthalmic surgery, urinary calculus, and miscellaneous papers on tropical surgery. Section VI—Exhibition and lantern slide demonstrations. Special consideration will be given to the part played by parasitic insects in the dissemination of diseases peculiar to the tropics, the geographical distribution of those insects, and suggestions as to the best means of obviating their attacks; the etiology, pathology, prophylaxis, and treatment of beriberi and plague; the bacteriology of and special methods of treatment of leprosy; the differential diagnosis of the various types of malarial fever and dysentery. All communications should be addressed to the general secretary of the congress, W. E. Jennings, M. D., D. P. H., Lieutenant Colonel, I. M. S., care of Messrs. Kinn, Kinn & Co., Bankers and Agents, Bombay, India.

COLONEL WILLIAM CRAWFORD GORGAS,

ASSISTANT SURGEON GENERAL, UNITED STATES ARMY, PRESIDENT  
DIRECT OF THE AMERICAN MEDICAL ASSOCIATION.

Born in Mobile, Ala., October 3, 1854; A. B., University of the South, Sewanee, Tenn., 1875; M. D., Bellevue Hospital Medical College, New York, 1879; now Chief Sanitary Officer of the Canal Zone, Panama.

## Pith of Current Literature.

### THE BOSTON MEDICAL AND SURGICAL JOURNAL

June 4, 1908.

1. New Duty of the Medical Profession: The Education of the Public in Scientific Medicine. President's Address Before the American Medical Association.  
By HERBERT L. BURRELL.
2. The Use of Silk Ligaments in Addition to Muscle and Tendon Transference in Infantile Paralysis.  
By ROBERT SOUTTER.
3. A Report of Some Atypical Cases of Tonsillar and Peritonsillar Inflammations with One Unusual Complication.  
By W. H. MERRILL.
4. The Early Diagnosis of Typhoid Fever by Blood Cultures from the Ear.  
By O. R. MABEE and A. E. TAFT.  
By G. P. SANBORN.

**2. The Use of Silk Ligaments in Addition to Muscle and Tendon Transference in Infantile Paralysis.**—Soutter describes his procedure as follows: In attaching the ligament to the tibia, the periosteum is slit longitudinally. No. 14 or 16 or 20 silk is quilted up the everted edge on one side and down the everted edge of the other side of the slit. This gives a very strong attachment, which cannot be pulled out. Three or four stitches are taken on either side. The everted edges of the periosteum are sufficiently loose to answer in the same way as any soft tissue in stretching down with the growth of a child, while in an adult it makes a very strong attachment. The double silk is then carried down and inserted well under the periosteum and superficial portion of the bone by means of a blunt pointed, short curved needle with a handle, somewhat similar to a Cleveland needle in shape. The needle does not, however, open. When it has been passed through the bone the eye is brought to the surface. The two ends of a piece of silkworm gut are passed through this eye, then the needle is withdrawn and pulls the silkworm gut doubled through the hole in the bone. This leaves two ends of the silkworm gut protruding from the bone at one hole and a loop from the other. One end of the silk tendon is passed through the loop of the silkworm gut. Then the silkworm gut is pulled out, bringing with it one end of the silk tendon. This method is used in order not to enlarge unnecessarily the hole in the bone. In tying the knot the ends are left a little long, so that they will bend down. The fascia is brought over the silk and knot by means of interrupted catgut sutures, subcutaneous tissue, and skin by means of interrupted catgut or horse hair sutures. Plaster of Paris bandage is worn from eight to ten weeks, then a brace to limit the extremes of motion. This is removed at night and during the day for muscle training and exercise. After four months a small brace inside the shoe is worn for long walks only. The correction and prevention of distortion is immediate. Some patients have good motion from the transplanted muscle, some starting motion, but in all the foot is maintained firmly in a position of greatest usefulness.

**4. The Early Diagnosis of Typhoid Fever by Blood Cultures from the Ear.**—Mabee and Taft observe, that blood cultures in early cases of typhoid fever (that is, within the first week) give an accurate diagnosis in 90 per cent to 100 per cent. The information obtained in this way is, therefore, extremely valuable, because the Vidal reaction is

rarely obtained before the ninth or tenth day of the disease. The simplicity of the method of obtaining blood from the ear for blood cultures warrants its general use by practitioners. In early cases 1 c.c. of blood is sufficient for each culture. In cases of two and three weeks' duration a larger quantity of blood gives a higher per cent. of positive cultures. In febrile conditions of a few days' duration with symptoms simulating typhoid fever a negative blood culture probably excludes typhoid fever. In septiciemias due to the *Staphylococcus pyogenes aureus*, it is possible to recover this organism from the blood by the ear method with the use of ox bile as a culture medium.

By LEO LOEB.

**1, 2, 3. Addresses and Orations at the Fifty-ninth Annual Session of the American Medical Association.**—See *New York Medical Journal*, June 6th.

**4. Varicocele and Its Treatment.**—Boland remarks that varicocele is a common condition, being found in ten per cent. of all men between the ages of fifteen and thirty. Unsatisfied sexual desire and excessive intercourse have been ascribed as causes. The former must influence the trouble, since it sometimes disappears in young men after marriage. No doubt a predisposition may be inherited. Occupation plays a part in the causation, since varicocele is common among men who stand a great deal, such as clerks, bookkeepers, etc. More than ninety per cent. of cases occur on the left side, the explanation of which is on anatomical grounds. The veins in the left cord are larger, the testicle hangs lower, and the left vein empties into the renal vein at a right angle, while the right vein empties into the vena cava at an acute angle. Again, the left spermatic vein, as it runs behind the sigmoid flexure, is constantly subjected to pressure from the accumulation of feces in the bowel. It is said that the modern habit of "dressing" on the left side tends to increase varicocele on that side, and that mild cases sometimes are improved by changing to the right side. A very large varicocele may produce no symptoms, while a small one often gives rise to pronounced symptoms, depending largely on the effect on the patient's mind. In a large number of cases the mental effect is the main feature of the disease and requires an operation for its relief. This is particularly true when the condition is associated with masturbation, the patient then being tormented by impotence. There is a general idea that masturbation is com-

nected with the cause of varicocele. Operative treatment is best and can be carried out under local anaesthesia, but a general anaesthetic is more satisfactory. The textbooks recommend ablation of part of the scrotum as being occasionally indicated, but in the south, where the pendulous scrotum is so common, it is generally indicated. Cures by this procedure alone have been reported. Certainly it is one of the most important steps in the operation. The shortened scrotum affords a natural and permanent support for the cord and testicle. But the best method, in the author's opinion, is the open method. By this procedure two incisions are avoided, as the veins may be removed through the same opening. Inspection of the testicle and tunica vaginalis is afforded, which in a large proportion of cases will reveal a hydrocele. It is well to give attention to small details in the operation, because so often it is performed on neurotic patients on whom the neglect of such details will have considerable mental effect. For instance, in ablating the scrotum a curved clamp should be used, or the ends of a straight incision rounded off in order not to leave any little elevations of tissue. These would absorb in a short time, but their presence will annoy some neuroathenic individuals while they remain. A curved scrotal clamp or two curved long jawed forceps are employed to hold the scrotum while the redundant portion is being removed. The clamp is pressed hard against the testicles, in a longitudinal direction, and as much subcutaneous tissue as possible pressed out before cutting. This lessens the number of vessels that will be cut. After severing the scrotum with knife or scissors the clamp is taken off and all bleeding points are carefully caught and tied with fine catgut. The varicosed pampiniform plexus is now exposed as far away from the testicle as possible and separated from the vas deferens with its artery and veins. The plexus lies with the spermatic artery in a separate sheath which need not be split. Sometimes the separation is difficult on account of adhesions which exist as a result of inflammation. Ligation of the spermatic artery does not impair the nutrition of the testicle. The vas deferens is easily recognized by its cordlike feel. It must not be handled unnecessarily, and is held aside with its vessels while a double chromicized catgut ligature is passed around the veins. This is separated and the veins firmly tied in two places two inches apart, the lower ligature being tied first. The intervening section is now removed, care being observed to leave the stumps long enough to prevent slipping. The ends of the ligatures may be left long and the cord shortened by tying them together. This saves time, but leaves a lump which will persist for several weeks to vex a nervous patient. It is better to approximate the ends of the veins and stitch them together. The wound is closed longitudinally with interrupted silkworm sutures, the ends of which are left long and tied together, as short ends will irritate the sensitive scrotum. Drainage usually is not necessary. Rubber tissue or oiled silk is placed over the dressing to prevent the possibility of contamination by urine. The dressing is held in place by a figure of eight roller bandage which supports the testicles. After a few days it is convenient to use a smaller dressing and a large suspensory bandage. The pa-

tient is kept in bed for ten days, and a suspensory worn only until the wound is thoroughly healed, then discarded.

**6. Comatose Pernicious Malaria.**—Neer says that the main points to be considered in distinguishing it from apoplexy are the age and general appearance of the patient, the splenic enlargement, the higher temperature in malaria (though this is not constant), and, of course, the examination of the blood. Malarial coma sometimes quite closely resembles sunstroke, and the heat may aggravate or precipitate a severe malarial paroxysm. In such cases an examination of the blood is often the only means of determining the presence or absence of malarial infection. From the urinary examination alone it would be impossible to distinguish comatose malaria from uremia. Albuminuria and cylindruria exist in both conditions; therefore, it is necessary to rely on other data. Quinine should be given hypodermatically. It may be given in the form of the hydrochlorate, the bisulphate, or quinine hydrochlorate, and urea. Regarding the dosage there is some difference of opinion. Osler advises 30 grains of the bisulphate hypodermatically with 5 grains of tartaric acid every two or three hours, or 10 grain to 20 grain doses of the quinine and urea hydrochlorate. Craig thinks 8 grains of the hydrochlorate, repeated until 24 grains have been injected, is sufficient in most cases, but admits that in very severe infections more of the drug may be needed. Bacelli first recommended the intravenous injection of quinine, and this method may be used in the presence of very grave symptoms. Aside from specific therapy, treatment must be symptomatic. Stimulants, especially strychnine, are often useful.

#### MEDICAL RECORD

June 6, 1908.

  7. The Convalescent Period, and Its Successful Management,  
By W. PARKER WORSTER.
- 1, 2. **Orations.**—See *New York Medical Journal*, June 6, 1908.
3. **Comments Upon an Unusual Case Requiring Cæsarean Section.**—Dannreuther describes this case as follows: The patient, eighteen years of age, belonged to a troupe of midgets. She had had rickets when six months old. She was well nourished, and apparently in excellent general health; height three feet eight inches; had no perceptible enlargement of the thyroid gland, and no pressure symptoms. Abdomen measured three feet six inches in circumference. No cardiac murmurs. Lungs clear. The diaphyses of the long bones were underdeveloped, while the epiphyses seemed almost normal in size. Pelvic measurements were: Interspinous, seven inches; intercostal, eight and one half inches; external anteroposterior, five and one half inches;

right external oblique, six and one half inches; left external oblique, six and one half inches; internal conjugate, one and one quarter inches; internal anteroposterior, one and one half inches. An incision was made through the abdominal wall in the linea alba, extending from one and one half inches below the ensiform cartilage to the symphysis pubis. Second incision through the uterus *in situ*, in the middle third of the median line. Time, thirteen seconds. No attempt was made to control the bleeding from the abdominal wound, which was inconsiderable. The child was quickly seized, the cord being clamped and cut, and was taken to another room. Artificial respiration was unnecessary, as the child cried lustily immediately after extraction. The child delivered, a nurse began pouring a continuous stream of normal saline solution, at a temperature of 120° F., directly upon the uterus. This promoted rhythmic contractions, facilitating the removal of the secundines, and controlling hæmorrhage. Three layers of continuous catgut sutures were introduced into the uterine wound; two into the musculature, and one into the peritonæum. One operator completed the first suture while the other began the second, etc. No attempt was made to sponge out the abdomen, the saline solution being purposely allowed to remain. The abdominal wound was closed by a continuous through and through chromic catgut suture, reinforced by silkworm gut interrupted skin sutures. Time, from the first incision to the late suture, thirteen minutes. The anæsthetic used was chloroform, followed by ether, which the patient took well. The pulse did not rise above 88, and was of good quality throughout. The baby was well nourished and developed in all respects, weight, seven and one half pounds. Mother rallied well after operation. Recovery was uneventful, the abdominal wound healing by first intention. Sutures were removed on the tenth day. The cervical canal being well open, dilatation for drainage was unnecessary. Lochia normal. The mother secreted but a minimum quantity of milk, so the baby had to be fed artificially. Both were discharged from the hospital in excellent condition four weeks after the operation.

5. **The Art of Surgical Knot Tying.**—Duncan describes a new system of knot tying, introduced by Dr. R. E. Brennan from Germany. It comprises two different knots, each of which may be tied with either hand, the square sailor's or reef knot, and the double surgeon's knot. It is impossible to describe it without giving illustrations.

6. **Urticaria Following the Second Administration of Diphtheria Antitoxine.**—Blain observes that the second immunizing dose of antitoxine should be given with caution, especially to individuals of the blond type, regardless of how long previous the first was administered. Should an individual who has at some previous time received antitoxine become exposed to diphtheria, it is better, in my opinion, if facilities are such that the exposed person can be kept under observation, to delay the administration until symptoms of diphtheria appear. Further, in cases of direct exposure to diphtheria the possibility of contracting the disease is comparatively small. In persons in whom an immunizing dose of antitoxine has been given, and who later

contract diphtheria, an attempt should be made to regulate the dosage in comparison with the severity of the infection, and not to push the serum too far, and thus overneutralize the toxine, possibly producing this distressing condition. A positive clinical diagnosis of diphtheria is often utterly impossible, regardless of the amount of experience possessed by the clinician, and consequently all suspicious cases should be treated as diphtheria, and as diphtheria by antitoxine, until proved otherwise, since the possibility of trouble caused by the antitoxine is not to be compared with that of the danger from diphtheria.

7. A Case of Ochronosis, By L. C. E. HARSTON and A. B. SOLTAU.
8. Satinwood Dermatitis, with a Suggestion as to Treatment, By F. GARDINER.

2. **Oil of Turpentine.**—Smith states that oil of turpentine has been undeservedly neglected. Possible irritation of the kidneys is usually apprehended, but small doses such as five or ten minims have no such effect, and in large aperient doses (two drachms to half an ounce) the action of the oil is entirely upon the bowels, and but little is absorbed. It is only the moderate dose of from one half to one drachm that is to be feared. In cases of hæmorrhagic purpura the oil of turpentine is of the greatest value as a hæmostatic. It should be given as an aperient with castor oil, and in sufficiently large dose. For children of from ten to twelve years of age, as much as half an ounce each of the two oils should be given every morning or every other morning. The best time for administration is an hour after food. In most cases of purpura recovery takes place within a week. Even should hæmaturia take place, there is no cause for alarm, as it quickly stops when the drug is discontinued. Other forms of hæmorrhage may also be quickly checked by the use of turpentine—in hæmophilia a large aperient dose may check the bleeding when all other measures have failed. Local bleedings, such as hæmoptysis and the hæmorrhage from typhoid ulcers, may be checked in the same way as in doses being used. One of the most valuable uses of oil of turpentine is its internal administration in small doses as an antiseptic and sedative in cases of flatulent colic and unhealthy states of the intestinal mucous membrane. This is especially true in the aggravated flatulence and colic occurring in hand fed infants. In cases of hiccoughs ten drops of oil of turpentine with thirty drops of nitrous ether often has a striking effect. The curative value of oil of turpentine when given by the mouth may often be supplemented and in-

forced by its internal use in enema. In cases of thread worms its vermifugal action is strikingly manifested.

3. **Puerperal Eclampsia.**—McCarthy's article is based on a series of eighteen cases of puerperal eclampsia. The convulsions are very similar to uremic convulsions—in both the convulsions are probably brought about by a toxine the origin of which is faulty elimination on the part of the kidney. The stage at which the convulsions threaten or occur will indicate the nature of the treatment. In the premonitory stage, where they threaten before labor occurs, the treatment should tend to avert toxæmia. All the care in treatment that would be given to an early case of nephritis, especially that relating to diet, should be carried out. Nitroglycerin may be very useful. The period of labor itself may be divided into two stages: (a) Where the convulsions are slight and the labor slow, the object should be to avert convulsions. The subcutaneous administration of morphine and nitroglycerin, used alternately, is beneficial in this stage. With a rigid os and increasing convulsions, Cesarean section might have to be considered. (b) When convulsions are increasing and labor advancing—even if the os is dilating well—all energies should be devoted to expediting labor. This is the stage where chloroform is essential and a drug of the greatest utility. When labor is over the treatment should aim at the restoration of the function of the kidneys and the recovery of the nervous system from the shock it has sustained. The writer was led to the use of nitroglycerin in puerperal eclampsia, because of the favorable results following its use in cases of contracted kidney. Of five cases of puerperal eclampsia treated without nitroglycerin, three died. Of two cases in which it was given internally only, one died. Of eight cases in which it was given hypodermatically, only one died. The mortality among infants was four out of fifteen, or about 26.7 per cent.

5. **Absorption of Ointments.**—Sutton has tested the relative absorption of the various ointments by means of aniline dyes. Guinea pigs and white rabbits were used, the ointment with the dye being applied to a bare place on the skin. After a certain time the patch was excised under anæsthesia, and sections cut and examined. He found that lard, simple or benzoinated, and pure goose grease were the most quickly absorbed of all the substances tested. Petrolatum is a poor penetrant unless applied with friction. Lanolin, alone, is absorbed very slowly; mixed with a more fluid material, as olive oil, it readily enters the skin. The addition of a small amount of cedarwood oil to an ointment considerably increases the rapidity of absorption.

6. **Treatment of Syphilis.**—Power discusses the latest advances that have been made in the treatment of syphilis, and reaches the following conclusions: 1. Experimental evidence has shown that syphilis is due to infection with *Spirochæta pallida*, an organism which lingers for a short time at the seat of inoculation and then rapidly spreads throughout the body. This organism, transmitted from father to child, is the cause of inherited syphilis. 2. Many forms of arthritis formerly classed as syphilitic are due to other infective agents acting upon tissues modified by the action of the syphilitic virus.

3. Syphilitic changes in the bones, joints, tongue, and other parts may occur as a result of inherited syphilis much later in life than is usually recognized. They are then the result of accidental causes, and they are often the only evidence of the inherited taint. 4. The modern treatment of syphilis consists (a) in the more careful administration of mercury, which is now given to cure the disease itself and not merely to relieve the symptoms, as has hitherto been the case; (b) in a recognition of the limitations of the absorptive power of the iodides; (c) in a freer use of surgical methods to remove the products of syphilitic inflammation before the iodides are administered.

By H. CURTIS.
7. A Method of Suturing the Lateral Recti to Insure Greater Mobility of the Stump after Enucleation of the Eyeball.  
By E. CLARKE.

1. **X Rays in Appendicitis.**—Bennett calls attention to the fact that the diagnosis of appendicitis is neither easy nor sure. This is shown by the fact that in many cases the appendix is found to be normal after removal, while in other cases the operation fails to relieve the symptoms. Various conditions give rise to symptoms so closely resembling those of chronic appendicitis that the distinctive diagnosis is extremely difficult. The principal of these conditions are: Inflammation about the ovaries and pubes; tuberculous glands in the iliac region; stone in the ureter; gallstone in the cystic duct; stone in the movable kidney; and malignant disease of the iliac bone. In some of the deceptive cases the cardinal sign of chronic appendicitis—swelling or induration—may be absent. But in the dangerous pelvic type of appendicitis there may be no objective abdominal symptoms, and in the presence of other indications the mere absence of swelling or of abdominal rigidity is no justification for setting aside the possibility of organic appendix disease. Failing some objective sign in cases like these, only two methods are available for clearing the matter up—an exploratory operation on the one hand, and the use of the x rays on the other. The operation may do no harm, the x rays cannot. The result with the rays may be *nil*, but they may disclose a stone in the ureter, a mass of tuberculous glands, a growth in the pelvic bones—any of which might cause the symptoms of which the patient complains. So that, in a case of abdominal pain of any but an obvious kind, all diagnostic resources have not been exhausted until the result of an x ray examination has been seen. There is still far too strong a tendency to decline the aid of x ray examination because it is unlikely

to give positive information, yet if made by a competent person it will invariably show stones in the kidney, ureter, and bladder, caseous tuberculous glands, new growths of bone, concretions in the appendix, sometimes stone in the gallbladder and tuberculous disease of organs; and, of course, metallic and bony foreign bodies. Under favorable circumstances even the existence of a diaphragmatic abscess can sometimes be shown.

4. **Malarial Cirrhosis of the Liver.**—Tucker states that cirrhosis of the liver, due to chronic malarial poisoning, is not of infrequent occurrence in Bombay, and that, too, in young children, where all the possible contributory causes except malaria can be eliminated. Besides the liver, the stomach, spleen, and kidneys are severely affected. There is a history of ill health and enlargement of the spleen for some years, with repeated attacks of intermittent fever. The enlargement of the spleen becomes marked, and there is a profound secondary anaemia. Later there is great emaciation and distention of the abdomen from collection of fluid in the peritoneal cavity. The fluid is not very abundant as a rule, and in many cases it does not recur after tapping. After weeks of treatment with iron, quinine, and arsenic the patient may improve greatly, and the spleen diminish in size. In the last stages there is profound debility and emaciation with the late toxæmic symptoms seen in other forms of cirrhosis. On opening the abdomen the most prominent object is the enormous spleen. The capsule is thickened and often adherent to one of the neighboring organs. The liver is somewhat small, but not as much so as in alcoholic cirrhosis. The red corpuscles may be reduced to 1,500,000 to the cubic millimetre. The malarial parasite present in the peripheral blood is usually the benign tertian. To sum up, therefore, we have in malarial cirrhosis a complex condition, of which the hepatic disease is the terminal event. Ascites is late. The finely granular surface of the liver is quite distinct from hobnail liver. The cirrhosis results from repeated attacks of malarial hepatitis and capsulitis, associated with perisplenitis and a plastic peritonitis. The adhesions resulting from the latter, along with the dragging of the enlarged spleen, produce extreme deformities of the stomach. Plastic peritonitis varies in amount, but is always a feature in the case.

5. **Acute Suffocative Catarrh.**—West reports a case of acute suffocative catarrh of Laennec, occurring in a man aged twenty-three years. It is a rare but characteristic disease, being an acute catarrh affecting the whole or a portion of the lungs, causing an acute suffocation. It lasts from twenty-four to forty-eight hours, at the end of which time either the patient dies or expectoration commences and puts an end to the suffocation, after which the disease goes on as an ordinary catarrh. The respirations are not very rapid, and the temperature and pulse are only moderately elevated. The clinical condition is unlike asthma or pneumonia, and there is no laryngeal obstruction. Examination of the chest shows nothing beyond coarse bronchi. In the case here reported, examination of the sputum showed pneumococci, and a diphtheroid bacillus. The condition has to be distinguished from capillary bronchitis and disseminated, posthumal, etc.

i. e., secondary—bronchopneumonia; more closely resembling it are primary bronchopneumonia—i. e., disseminated pneumococcal pneumonia and possibly an acute pneumococcal or other bacterial bronchitis. In association with it may be placed (1) cases of acute pulmonary oedema, which develop in the course of chronic heart obstruction or of acute heart failure; (2) cases of collateral fluxion or of pulmonary failure; and (3) cases of pneumonia which commence with widespread pulmonary congestion. A careful bacteriological examination of the sputum should be made in all cases of suffocative catarrh as being likely to throw light upon the true nature of the affection.

- Treatment of Facial Neuralgia by Local Alcoholization.  
By J. A. SICARD.

**Treatment of Facial Neuralgia by Local Alcoholization.**—Sicard asserts that the treatment of facial neuralgia by the injection of alcohol is the method of choice. He does not confine his injections to the foramen rotundum and foramen ovale, but finds that they are useful when made at other points of emergence. These foramina, or canals, of emergence, at which injections may be successfully made, he divides into three groups—the peripheral group, composed of the supraorbital, infraorbital, and inferior dental foramina; the median group, composed of the canals of the diploe in the inferior and superior maxilla, the inferior dental canal at the process of Spix, and the posterior palatine canal; and the deep group, composed of the round and oval foramina. The sphenoorbital fissure is purposely omitted because it is dangerous of access. The point of a fine platinum needle is carried down to one of these points, and a mixture of eighty per cent. alcohol with twenty per cent. distilled water is injected into the tissues. Stovaine may be added if desired, but not chloroform, because the latter sometimes excites a very considerable degree of inflammation.

10. Histological Demonstration of Acidose in Children, By G. TUGENDREICH.
11. Concerning the Value of Mollière's Methyl Violet Reaction in the Demonstration of Free Hydrochloric Acid in the Stomach, By WASSERTHAL.
12. Telephone for the Deaf, By P. LEBRAM.

**1. Stokes-Adams's Disease.**—De Renzi says that two characteristic signs have been ascribed to Stokes-Adams's disease—a permanently infrequent pulse and nervous attacks, syncope or epileptiform. But he thinks that the disease has a complex symptomatology and that there are other phenomena which are just as important, if not more so, than these two. First is an apparently infrequent pulse, in which there is a double contraction of the auricles to each systole of the ventricles. This is shown in several ways: 1. Radioscopy shows an alternate contraction of the auricle and of the whole heart. 2. In many cases the pulsation of the jugular is twice as strong as the arterial. 3. By a careful examination an alternation between a strong and a weak arterial pulsation can be detected. 4. In some sphygmograms a slight elevation can be detected between the two curves of the radial pulse. Second, are nervous attacks, dizziness, syncope or apopleptiform in character, proportioned to and the direct consequence of the infrequency of the pulse. Third, the infrequency of the pulse is scarcely influenced by psychic influences, muscular movements, changes of position, or drugs which accelerate the pulse. Fourth, slight dyspnœa. In contrast to the pulse which is constant the respiration changes easily and is productive of dyspnœa. Fifth, notable increase of the blood pressure. Sixth, alternation of the

rhythm of the heart. Seventh, renal changes and albuminuria.

**3. Idiopathic Osteopsathyrosis.**—Lipschütz reports a case of this disease, which is otherwise known as idiopathic brittleness of the bones, met with in a man, forty-one years of age. He discusses the symptomatology, the nature of the disease, former theories, the results of microscopical examinations and of the x ray examination of his own case, and the relations of idiopathic osteopsathyrosis to such diseases of the foetal skeleton as foetal chondrodystrophia and osteogenesis imperfecta. The latter he believes to differ from the disease under consideration only in the time of its onset.

**7. Hæmolytic Reaction of Blood Serum in Malignant Tumors.**—Fischel says that in many cases of malignant tumors the blood serum shows a hæmolytic reaction with the blood corpuscles of different kinds of animals. The hæmolytic reaction is not specific for the blood corpuscles of one kind of animal, as stated by Kelling. The hæmolytic reaction is not specific for malignant tumors, but is met with in some other diseases, particularly pernicious anemia and tuberculosis.

**8. Guaiac Blood Test.**—Rothschild asserts that his experiments show that the idea of Schröder that for the bringing out of the maximal stain by the tincture of guaiac a certain quantity of the tincture of a certain concentration is necessary, is correct in principle. With weaker concentrations of blood, for which the guaiac test is chiefly used in clinical investigations, he is convinced that the use of such a single guaiac tincture in such strength as is most suitable is best, and one makes no mistake if he undertakes the guaiac test with only a single solution of guaiac resin.

#### MÜNCHENER MEDIZINISCHE WOCHENSCHRIFT.

7. The Origin and Treatment of Intestinal Hernia, By KOCH.
8. The Treatment of Venereal Ulcers With Hot Irrigations, By ZINSSER.
9. Lysol Poisoning After Washing Out the Uterus, By PILITZ.
10. Abscess of the Kidney After Gonorrhœa. Nephrotomy. Recovery, By WEISSWANG.
11. Treatment of Intestinal Hæmorrhages in Typhoid Fever by Injections of Gelatin and Salt Water, By WITTHAUER.
12. A Practical Instrument for Physical Examination, By KRETSCHMAR.
13. The Question of Sanatorium Treatment and the Indications for the Same (Concluded), By FRANKENBÖGER.
14. New Points of View in the Treatment of Suppurative Processes, By MORO and MANDELBAUM.
15. Obituary of Franz von Leydig, By SCHULTZE.
16. The Physician and the Duty of Reporting Typhoid, By HILLENBERG.

**3. Acute Overexertion of the Heart.**—Schott finds as the result of his experiments, commenced in 1890, that bodily overexertions which are carried

so far as to produce a palpitation of the heart that can be felt, together with a severe dyspnea, will finally result in acute dilatation of the heart.

5. **Diabetes Mellitus as an Indication for the Induction of Premature Labor.**—Schottelius considers that the prognosis for the life of either the mother or the child is pretty bad when pregnancy is complicated by diabetes mellitus, and therefore recommends that, when no visible result is obtained by the internal and dietetic treatment of the diabetes, premature labor should be induced.

6. **Acute Atrophy of the Liver.**—Reichmann reports a case of this nature with the anatomical findings at autopsy. A point in regard to the etiology is interesting. Syphilis was particularly suspected to be the cause because the patient suffered also from a parenchymatous keratitis, but not only was infection of this nature denied by the patient and by his father, but no stigmata whatever of syphilis could be detected, aside from the keratitis, while living, or in the tissues after death. The cause of the atrophy of the liver remained obscure.

10. **Abscess of the Kidney After Gonorrhœa.**—Weisswange reports the case of a woman, thirty-four years of age, who was attacked with an abscess in the kidney six years after infection with gonorrhœa. Virulent gonococci were found in the pus.

11. **Treatment of Intestinal Hæmorrhages in Typhoid Fever by Injections of Gelatin and Salt Water.**—Witthauer declares that the subcutaneous injections of solutions of gelatin and of salt are remarkably effective. The injections of gelatin should be made every day or every other day, those of salt solution should be made more frequently, according to circumstances, until the hæmorrhage has stopped certainly a couple of days.

13. **Sanatorium Treatment.**—Frankenburger concludes that sanatoria form an important factor in the measures adopted for the stamping out of tuberculosis, that in the admission of patients to the sanatoria consideration should not be given to the statistics of results, but only to the benefits to be expected in each individual case. Patients in the first stage of the disease, persons suspected of having tuberculosis, and those with a latent form of the disease should be excluded from sanatorium treatment, because they can be treated equally as well outside by hygienic regulation of their lives, and by thus reducing the cost many more needy can be helped. The sanatoria are particularly for patients in the second stage of the disease. Admission to a sanatorium should not be permitted after a single examination, but only after previous observation at a hospital or elsewhere.

7. On the Serum Reaction of Syphilis. By M. H. TCHLENOFF.
8. Stenosis of the Larynx (Continued). By M. F. TSITOVITCH.

1. **Lipogenin in Ophthalmology.**—According to Agabavoff, lipogenin is a colorless, transparent liquid, neutral in reaction, which does not become altered on exposure to air. It is soluble in ninety-five per cent. alcohol, but not in glycerin and in water. It is a mixture of the ether of palmitic and isooleic acid. Lipogenin is made at a Russian soap factory in Kazan, and is prepared in the form of a liquid and in a crystallized solid form. Professor Agabavoff, of Kazan, in this article, recommends it as a solvent for alkaloids, as well as for a vehicle for iodoform in ophthalmology. Aqueous solutions of alkaloids used in eye diseases very readily decompose. The use of such decomposed solutions gives rise to conjunctivitis, etc. Carbolic acid and other antiseptics have been added to solutions of this sort to prevent decomposition. But these are either inefficient or injurious. It is not always possible to prepare the solution freshly with sterile water. Olive oil has been recommended for the preparation of these alkaloidal solutions as early as 1897 by Panas. It is very difficult to obtain pure olive oil which does not decompose, and the oil must be specially purified and sterilized. Lipogenin is a substitute for olive oil, which, according to Agabavoff, is superior to it. The author employed it as a dressing after plastic operations on the eye. He covered the wound with a disk of sterile gauze, soaked in sterile lipogenin, then with a layer of waxed paper, with a thick layer of cotton, and a bandage. The results were excellent. Lipogenin does not dry or adhere to the wound and dissolves iodoform, robbing the latter of its odor. Solutions of iodoform or of iodine are very useful in eye surgery. Iodine solutions have proved effective in the treatment of trachoma, the strength being from one half to two thirds per cent. Lipogenin dissolves atropine, eserine, pilocarpine, strychnine, etc., in considerable proportion, and the solutions are stable and nonirritating.

6. **Malachite Green in Culture Media for Typhoid.**—Padlefski recommends the following medium for the diagnostic culture of typhoid bacilli. The advantage of this medium is that the colonies of typhoid bacilli can be distinguished by the green, bright color. The medium is especially valuable because it prevents the growth of other intestinal microbes and promotes the growth of the typhoid bacillus. The medium consists of agar mixed with malachite green which has been rendered colorless with sodium sulphite. The addition of bile to this mixture, as well as of milk sugar, produces a culture medium in which the typhoid bacillus grows abundantly in the form of green colonies, while all other bacilli of the typhoid group grow at first in colorless and then yellowish colonies. Other admixtures of germs do not grow at all, or in colorless colonies. The typhoid bacillus, during its growth, decomposes lactose and forms an acid which neutralizes the action of the sodium sulphite and brings out the green color of the malachite. The medium is prepared as follows: To a three per cent.

meat agar, with two per cent. peptone, having a slightly alkaline reaction (to litmus), is added one per cent. of chemically pure milk sugar and three per cent. of natural ox bile which has been previously boiled and filtered. The agar is poured into flasks holding 100 c.c., which are sterilized in streaming steam for half an hour on three successive days. A one per cent. aqueous solution of chemically pure malachite green is prepared (*Malachitgrüne Zinkdoppelsalz Kristalle*). Next a solution of ten per cent. sodium sulphite is prepared. To each 100 c.c. of the sterilized and cooled agar are added 0.5 of the malachite solution and 0.5 c.c. of bile and 0.75 to 1.0 c.c. of the sodium sulphite solution. The mixture should be pale green in color and transparent. The agar is then poured in a very thin layer (about 3 mm.) into Petri dishes, which are allowed to remain open until they dry, then are turned upside down and dried from 10 to 15 minutes in a thermostat. When cool, the agar should be transparent and yellowish, without any greenish tint. The material to be examined should be spread by means of a curved glass spatula, without undue pressure over the agar. The agar need not be sterilized after the addition of the malachite solution. The solution of malachite keeps only for about a week. After the addition of bile and sugar, the agar should be tested and should be slightly alkaline. A slight excess of alkali does not harm. It is very easy to isolate typhoid bacilli with this method.

## AMERICAN JOURNAL OF SURGERY.

1. Some of the Modern Aspects of the Cancer Problem, By ROSWELL PARK.
2. Simplified Equipment and Management for the Operating Room, By W. S. SCHLEY.
3. The X Ray in Dermatology; or Truth and Fallacy Concerning X Ray Dermatitis, By ALBERT C. GEYSER.
4. The Submucous Operation of the Nasal Septum, with a Plea for a More Rapid Technique, By J. E. MACKENTY.
5. Blood Examination in Surgical Diagnosis. A Practical Study of Its Scope and Technique (*Concluded*), By IRA S. WILE.
6. Rectal "Don'ts," By JEROME M. LYNCH.

1. **Some of the Modern Aspects of the Cancer Problem.**—Park remarks that if there is anything peculiar that cannot be alleged of this disease it is that the cancer cell is its own parasite. It makes for some a pretty and attractive statement, but it is perfectly impossible. There is no other place in the body, nor other circumstances under which the body's own cells act as parasites. It has been held that the cells break up or degenerate and some portion of the degenerative product is capable of acting as a parasite. This is entirely undemonstrable and incredible. The author remarks to such statements that from this and many other evidences that might be produced it can easily be made to appear that the theory by which the cancer cell is erected into being its own parasite is far more revolutionary, and taxes the imagination far more, than the theory which seeks to find the explanation in some extrinsic agency, and which is already receiving such striking corroboration from both clinical experience and the experimental laboratory. He believes absolutely in the statement that cancer begins as a result of local con-

ditions. Cancer, with all its local characteristics and its fatal termination, is a disease without a symptomatology of its own. It is a disease without a distinctive or definite symptomatology. Regarding the curability of cancer, he states that he feels that if a case is recognized early, and if it is located in an accessible portion of the body, and if it were completely extirpated at that time, there would be a great probability of cure and with a much lower mortality. These "ifs," remarks the author, are tremendous in size, and yet he does believe in the curability of cancer. As Behla says: "If cancer is to be regarded as a constitutional disease there is but very little use in operating, since in that case there would be almost as much reason for amputating the foot of a gouty patient."

3. **The X Ray in Dermatology.**—Geysler concludes that the so called x ray burn is no more the direct result of the x ray than the same reaction when the part has been exposed to the ultra violet x ray, radium, or similar agents, and is, therefore, entitled to the name of radiodermatitis. The x ray when brought into direct contact with the tissues is far more active than radium and furnishes clinically better results. There is no accurate means at present whereby the effect of the x ray can be measured; the reaction is largely due to conditions existing within the body of the patient. The x ray is not a cure all, but has its indication in certain selected cases; whenever possible malignant growths should receive the benefit of radical removal by knife, cautery, or paste.

### Proceedings of Societies.

---

#### MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK.

*Special Meeting, Held in Brooklyn, March 2, 1908.*

Dr. J. SCOTT WOOD in the Chair.

**The Comparative Therapeutic Value of the Compounds of Iron.**—This paper, by Dr. RANSFORD E. VAN GIESON, the vice president, has been published in the *Journal* of April 11th, on pages 687 et seq.

Dr. REYNOLD WEBB WILCOX said that the iron question was in many respects an enormous one, though in its practical aspect it was comparatively simple. He had in his possession a copy of the *Edinburgh Pharmacopæia* of 1808, and in this iron appeared in four forms: (1) iron dust; (2) iron filings; (3) iron muriate (the chloride); (4) iron vitriol (the sulphate). Since then the preparations, both official and nonofficial, had multiplied very greatly. In the last revision of the *United States Pharmacopæia*, iron had been dealt with at considerable length. Every drug and preparation coming before the committee had to be considered from two points of view—the pharmaceutical side and the medical side. As regarded the latter, no article was admitted unless there were sound scientific reasons for its employment. With the hundreds of iron preparations brought forward they had done the best they could. Although the preparations were so numerous, the use of this remedy in practice was a simple affair. The points requisite for success with

it were, first, careful observation of the particular case to be treated, and, second, observation of the effects of the preparation, to see whether definite results were being produced by it. It should not be forgotten that the red corpuscles of the blood could be greatly increased in number without the use of medicinal iron. Thus, a milk diet would have this effect, although milk contained very little iron. Massage, static electricity, and other agencies, as well as ordinary wholesome food, also tended to produce the same result. As Dr. George B. Wood had said long ago, the best results were obtained when you sunned your patient. The use of such means cured secondary anemia, because the effect was to call into play the reserve store of iron in the liver. It was a very easy matter to find out whether the condition of a patient's blood was improving. It was not necessary to count the corpuscles (a very tedious and troublesome undertaking), since the percentage of red corpuscles was as a rule quite closely paralleled by that of the hæmoglobin, and this could be readily and quickly estimated by means of the hæmoglobinometer. During some years past he and his assistants had made more than twenty thousand hæmoglobin estimates. Physical signs (such as the different hæmic murmurs) also indicated quite closely the amount of hæmoglobin present. The quantity of nonsense which we heard about iron was appalling, and in this talk there was also a great deal always said about manganese. Having said that manganese was practically useless in improving the condition of the blood (as he had proved by some three thousand hæmoglobin estimates), Dr. Wilcox said that the only reasonable and scientific way to use iron was to select a single preparation, which seemed best adapted for the particular case, and then observe whether it had the desired effect, as shown by the actual increase of hæmoglobin. Any preparation of iron which did not add as much as 10 per cent. to the amount of this each week was not accomplishing what we ought to expect from this remedy.

Dr. H. A. FAIRBAIN said it would be an advantage if nine tenths of the iron preparations should be cut out of the *Pharmacopœia*. The large doses formerly advised were entirely unnecessary, as small doses were quite sufficient to accomplish the desired purpose. There was one preparation on which he was accustomed to rely almost exclusively, and that was the syrup of the iodide. As had been remarked, however, medicinal iron was not the only thing needed by anæmic patients. It was true that they required iron, but God had provided this in the sunshine and in good food.

Dr. VAN GILSON said that in his paper he had not referred to the iodide, because this was not commonly used for simple anemia, although it was most excellent in strimous conditions.

#### The Early Diagnosis of Cancer of the Uterus.

—Dr. ALBERT MARTIN, Iudo read this paper. Although the subject, he said, had been brought to the attention of the profession very frequently during the last decade, his experience had taught him that the question of an early diagnosis could not be too frequently brought to the notice of the general practitioner. In order to make an early diagnosis, the physician, wholly ignoring the climacteric as an

entity, should insist upon a digital and speculum examination whenever his patient complained of any untoward or unwonted pelvic symptom. More was learned by the finger than by the speculum. If the cervix was sound, and the discharges, whether bloody or leucorrhœal, came from the uterine cavity, the curette should be used as an aid to diagnosis. In all cases the microscope was to be called into requisition. While much was still to be desired in this regard, an early diagnosis was made more frequently at present than formerly, and, consequently, a less serious view of the disease must now be entertained; for many series of cases had been reported by the wisest and most respected surgeons in which a large percentage of cures were effected. By complete cure he meant with no recurrence after five years. Our operative treatment of cancer had taken a long step forward when the modern theory that it began as a local disease was established. There were certain types of uterine cancer which ran a more malignant course than certain others, and two cases illustrating this aspect of the disease were cited by the speaker.

The classical symptoms of cancer of the uterus were hemorrhage, offensive discharge, and pain. Unfortunately, when these were all present, the disease was but too often no longer localized in the uterine tissues. When the symptoms of cancer were analyzed, therefore, it was seen that the early diagnosis must depend upon other than the classical signs. Very often women would complain of pelvic symptoms common to several diseases, and the diagnosis had to be made by the physical findings, aided perhaps by a microscopical study of a portion of the suspected tissue. It was his opinion that one should not say that a given case was inoperable until the patient was examined under an anæsthetic, the uterus drawn down by a volsella, and a thorough curetting done, unless (and this was very important) there was unmistakable evidence of the existence of secondary cancerous growths in other portions of the body. The ordinary appearance of the symptoms of carcinoma of the uterus was in the following order: Ichorous leucorrhœa, pelvic pain, fetid discharges, and general cachexia. But while these symptoms were characteristic, some of them might be absent, or their sequence might be variable. Thus, pain might not be present. In other instances hemorrhage would be the first symptom, and again, loss of weight and general cachexia, ordinarily the final manifestations, might be the first to attract attention. As had been stated, a digital examination, supplemented by the microscope, was the only method of arriving at any conclusion. This should never be neglected in any case of painful coition, stubborn pelvic pain or backache, leucorrhœa, and especially metrorrhagia or menorrhagia. A show of blood, however slight, following sexual intercourse, should always awaken suspicion.

Having spoken of the technique in obtaining a specimen for examination, Dr. Judd called attention to a condition which the general practitioner saw and treated, namely, erosions or ulcerations of the cervix, as they were commonly called. An erosion, he said, was never a discrete. It was only a symptom. Generally speaking, it was caused by some irritative discharge from the cervix or uterus. This

latter might be produced by an inflammatory change in the mucosa of the cervix or of the body of the uterus, or might be an expression of some constitutional trouble. It seemed but logical that the cure of an erosion was to be accomplished only by the cure of its cause, but we still saw many cases which had been treated by local applications to the erosion itself. The protracted course of such treatment led to unavoidable delay in diagnosis, and delays were sometimes fatal to the patient. Many of these cases could be cured by office treatment. He did not hesitate, in a case of so called endotrachelitis, to curette the cervix in his office, though patients whose discharge came from higher up had to be curetted under an anæsthetic. Constitutional causes should be treated constitutionally. The diagnosis of cancer having been made, only one course was left to the conscientious physician, and that was operative treatment—removal, if possible; if not, curetting or cauterization.

Following the paper there was a prolonged discussion, only the more important points of which can be here given.

Dr. GEORGE MCNAUGHTON said that one great difficulty in making an early diagnosis was the fact that so many patients concealed their symptoms until the disease had made fatal progress. It was, therefore, a matter of the greatest importance that a campaign of education should be carried on, so that women might be brought to understand that certain troubles which they supposed were due to the menopause had nothing to do with this, and required the immediate attention of their physician. Ninety per cent. of the cases of uterine cancer were in the cervix, and, therefore, readily amenable to operation, if this was undertaken in time. The microscope would decide the matter in any case of doubt. The scrapings from the body of the uterus usually gave the pathologist the means of making a satisfactory examination, but the curettings of the cervix were not satisfactory. He had therefore devised an instrument for obtaining specimens from the cervix which was a slight modification of the adenoid forceps. The importance of early diagnosis was a point which could not be too strongly urged. It should be reiterated again and again, and when it had become more generally recognized, a fair proportion of the patients could undoubtedly be saved.

Dr. L. GRANT BALDWIN having also spoken of the importance of a campaign of education for women, said that, as regarded different degrees of malignancy, he believed much depended upon the age of the patient. If she was above fifty, the disease would be apt to recur less frequently and to be less malignant than in a younger woman, in whom all the functions of the economy were more active. Loss of blood was the great sign of all others, and every case of hæmorrhage should be carefully investigated. The spottings between periods were particularly significant, and with the hæmorrhage there was often associated a thin, watery discharge. In some cases, however, there were absolutely no symptoms until the disease had made fatal progress. There was nothing distinctive about the odor of cancer, and also the cachexia from sloughing fibroids was very much the same as that from cancer.

Dr. R. H. POSTEROV said that, while leucorrhœa

was by no means pathognomonic of cancer, it was almost invariably one of the early signs of this disease. All the ordinary cases of leucorrhœa were curable, and if in any instance the cause of the discharge could not be found and treated, it was fair to suspect the presence of cancer. A test that had been proposed for determining the existence of cancer when there was erosion of the cervix was the application of a ten per cent. solution of copper sulphate. If the granulations healed under this treatment it would show that there was no cancer, while the reverse of this would be true if they did not heal.

Dr. A. ERNEST GALLANT said it was natural that we should fail to recognize the early signs of cancer, because there really were no symptoms which could properly be called early. As to what are generally known as erosions of the cervix, he had never seen a case of this in which the condition was followed by cancer. He had found that these erosions were best treated by means of the application of pyroligneous acid, repeated until they healed, and as an adjuvant to this he employed douches of ordinary vinegar. If there were a cancerous condition of the cervix, however, this treatment would have no effect. Women frequently had cancer long before the menopause, and he had seen a patient of thirty with enormous cauliflower growths. He believed there was great danger of the cancerous degeneration of fibroids. It would not do, therefore, to tell patients with fibroids that they would get well when they reached the menopause. There was a cachexia from fibroid, and he was opposed to letting a patient with such a tumor go on to this third stage. He would operate early, for the prevention of future trouble, just as he would in appendicitis. While no one had greater respect for the work of the pathologists than himself, he had found that they sometimes made mistakes, and he knew of three cases where the uterus, which had been pronounced cancerous, had been taken out, when syphilis was really at the bottom of the trouble. He therefore always gave his patients a thorough course of antisyphilitic treatment before he consented to operate. He did not believe there was a pathologist living who could always decide correctly in a case of suspected cancer, and where the disease was located in the body of the uterus, it was manifestly unfair to expect the examiner to make the diagnosis from a few scrapings from the lining of the cavity. To afford a proper opportunity for decision, the curetting should be deep.

Dr. ARCHIBALD MURRAY, having referred to some of the difficulties with which the pathologist had to contend, said that in any case, where the disease was in the body of the uterus, he thought that in securing a specimen for examination the uterus should be thoroughly curetted, and, if possible, some of the underlying tissue obtained, as well as some of the sound tissue on either side also. He did not think it fair to ask a diagnosis from a little mucus on a tampon. If the specimen was kept in water or presented dry on gauze, not much could be done with it. The surgeon was apt to expect too much of the pathologist, and in many instances the early diagnosis of cancer was just as difficult for the latter as it was for the surgeon.

Dr. JUDG said that personally he had never seen

a case of cancerous degeneration of fibroids, although for years he had been on the lookout for this.

**Experiences in the Field of Œsophagoscopy.**—The last paper of the evening was by Dr. JOSEPH MERSEBACH, on this subject. He said that he had no original views to present, but simply desired to speak of the results of some of his examinations, and to consider to what extent these investigations had supplemented clinical observations. The instrument employed was the Mikulicz œsophagoscope, and the patient examined was placed in the horizontal position. Except in one instance, local anæsthesia was used; at first a twenty per cent. solution of cocaine, and afterward (as poisoning was once caused) a ten per cent. solution. At his last examination he employed general anæsthesia, and as the result of this experience he now believed that, in making the examination, this should always preferably be resorted to. In two cases previously he had failed to introduce the instrument because of his inability to overcome the nervous irritability of the patient. The speaker then proceeded to give a condensed report of cases, each one of which was illustrative of one of the four groups in which he had made examinations. The first was a case of carcinoma, the second one of idiopathic dilatation of the œsophagus, the third one of syphilitic tumor, and the fourth one of foreign body. By way of comment, he said it was doubtful whether the limited number of his cases entitled him to form any conclusions as to the value of œsophagoscopy, but, so far as he had been able to form any opinion from his personal experience, it would be in the direction of not attaching too much importance to the diagnostic significance of such inspection. In malignant growths the diagnosis could usually be made by other methods, and the diagnosis between a diverticulum and a dilatation could also be arrived at by other means. In the extraction of foreign bodies, however, the œsophagoscope was undoubtedly far superior to the method of probing in the dark, and even to the removal by the aid of the x ray, which was, of course, not applicable to all foreign bodies. Here the œsophagoscope was the only rational instrument, and it ought to be considered indispensable. If he had succeeded in establishing the diagnosis of syphilis in one instance, the value of this discovery could not be exaggerated, since it afforded the inspiration to institute antisyphilitic treatment in the otherwise hopeless cases of œsophageal tumor.

Dr. MAX FREUDENBERG said that, in December, 1900, he had had the honor of first demonstrating his new œsophagoscope before this association. In the older instruments the source of the illumination was outside of the œsophageal tube, while in his own a better illumination was secured by placing the lamp at the lower end of the tube, near the area to be examined. In examinations with the œsophagoscope he thought that neither cocaine nor general anæsthesia should be resorted to. When intolerance was present it was impossible to say what might not happen. With all these instruments the introduction involved, under any circumstances, a considerable amount of danger to the patient. In the case of his own œsophagoscope, at least, the sitting posture was preferable to the recumbent for the intro-

duction, though later the patient might lie down with the instrument in place. In some instances the horizontal position afforded a better opportunity for the observations required. In his opinion the œsophagoscope as a diagnostic means was of very great value. As an illustration of this, Dr. Einhorn cited the case of a lady who had a small tumor of the stomach. On account of the difficulty she had in swallowing, it was suggested that an operation should be performed. Before consenting to such a procedure he thought it would be well to make an œsophageal examination, and when this was done it showed very distinctly that there was a continuation of the tumor into the œsophagus, a condition which rendered an operation entirely inadvisable. Again, there were certain cases in which there were very grave symptoms, and yet when the œsophagus was inspected nothing was found. Here the instrument was of service in excluding dangerous conditions, and such patients were benefited by medicines. In one case that he had observed there was a reddening or perhaps inflammation of the œsophageal mucous membrane, but no obstruction whatever. Without the œsophagoscope it would have been difficult to make a correct diagnosis, and under appropriate treatment this patient got entirely well.

### Book Notices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

**Diseases of the Heart.** By Professor TH. VON JÜRGENSEN, of Tübingen; Professor Dr. L. KREHL, of Greifswald; and Professor Dr. L. VON SCHRÖTTER, of Vienna. Edited, with Additions, by GEORGE DOCK, M. D., Professor of Medicine, University of Michigan. Illustrated. Philadelphia and London: W. B. Saunders Company, 1908. Pp. 848. (Price, cloth, \$5; half morocco, \$6.)

In the collaboration on this well known volume of Nothnagel's *Practice*, Professor Krehl has been assigned the subjects in which the advances have, perhaps, been greatest in recent years. As he is equally esteemed as a pathologist, a brilliant investigator, and a clinician, his discussion of diseases of the myocardium, the cardiac neuroses, arteriosclerosis, and coronary disease are marked by the originality of view, scientific caution, and soundness of deduction which would be expected by the student familiar with his *Pathological Physiology*. The American reader will be struck by the significance attributed by the newer school of German observers to the influence of alcohol and tobacco as causes of the chronic degenerative changes in the heart and bloodvessels. In the sections on treatment a conservative, but, on the whole, a moderate opinion is expressed as to the value of the Nauheim system of baths and resistance exercises. The sodiosulfate of the bromine is praised as a diuretic. There is a masterly review by Krehl of the action of digitalis, from which we cannot refrain from quoting the following: "The physician must make himself thoroughly familiar with the properties and uses of this drug, for it is not enough for him to know that digitalis is the remedy to give; he must also know how, when, and how much of it to ad-

minister. It is my belief that an adequate knowledge of this one substance would enable a physician to dispense with all other 'heart remedies'; but all other remedies taken together, without digitalis, are inadequate." The subjects of cardiac insufficiency, endocarditis, and valvular lesions are dealt with in an adequate and scholarly manner by von Jürgensen, who cites numerous illustrative case histories from his own wide experience, and makes frequent references to the important literature. In a work so complete it would seem to be an omission that in the discussion of rheumatic endocarditis there should be no mention of the recent contributions of Poynton and Paine. In the concluding chapters diseases of the pericardium, including syphilis and new growths, are well described by von Schrötter. Valuable addenda in brackets by the editor round out and complete the work for the reader in this country by giving all the references to important American literature. This fine volume will doubtless long remain a standard reference work on diseases of the heart.

*Surgical Emergencies.* By PERCY SARGENT, M. A., M. B., B. C. (Cantab.), F. R. C. S., Surgeon to Out Patients, St. Thomas's Hospital, etc. London: Henry Frowde (Oxford University Press) and Hodder & Stoughton, 1907. Pp. 256.

The author has availed himself of some eight years' experience in St. Thomas's Hospital to prepare this account of the methods to be employed in the treatment of hæmorrhages, burns and scalds, fractures, pus infections, abdominal injuries, hernia, and injuries of the neck, chest, nervous system, ear, and eye. The directions are brief and practical and the manual is handy in size.

*Heredity.* By J. ARTHUR THOMSON, M. A., Regius Professor of Natural History in the University of Aberdeen, Author of *The Study of Animal Life*, etc. With 49 Illustrations. New York: G. P. Putnam's Sons; London: John Murray, 1908. Pp. xvi-605.

That the subject matter of this work concerns itself with facts and fancies which are not only fascinating in their interest, but of great practical importance, few will dispute. But, unfortunately for the busy man or woman, either in the world of commerce or in that of science, the specialistic point of view has been reached so quickly, and the intricacies of the subject are so multiplied, and scattered in the transactions of learned bodies the world over, that there is need for just such a work as we now have before us, namely, an introduction to the study of heredity, from the nonpartisan point of view, by a student of biology whose equipment for the task is undoubtedly ample.

The evidences derived from the microscopical study of cell growth, pushed forward by Van Beneden, and in this country by Wilson; from the statistical data so well collected by Galten, Pearson, Davenport, and others in *Biometrika* and similar publications, and the results of experimental research have all been made use of to present to the reader the present day concepts of the general laws of heredity.

There is much loose thought and looser talk concerning the subject of heredity in disease. We are almost entirely in the dark so far as positive knowledge is concerned, and it must be confessed that our author contributes little new to the discussion;

but, fortunately, his chapter on heredity and disease, while not exhaustive, is sound, and the foolish talk about the heredity of diabetes, of insanity, of epilepsy, etc., concerning which too much is written, is largely omitted. The general attitude of the book is cautious and sound. It is a valuable addition in the form of a well digested summary, and as such commends itself to the thinking physician.

*Vorlesungen über Diätbehandlung innerer Krankheiten* von reiferen Studierenden und Aerzten. Von Professor Dr. H. STRAUSS in Berlin. Mit einem Anhang, "Winke für die diätetische Küche," von ELISE HANNEMANN. Berlin: S. Karger, 1908. Pp. 340.

Professor Strauss has laid down in this book his ideas about special dietetics in sickness. Questions relating to general dietetics are only touched upon in Chapter xv, and then in so far as they have reference to clinical problems. The dietetic treatment of diseases of childhood is also omitted, as the author thinks that should be the subject of a separate book.

Our book is divided into fifteen lectures, three being introductory and the twelve others treating of the object proper. Following his practical point of view, to be as condensed and concise as possible, the author does not give a special lecture to the diseases of the lungs and to infectious diseases, as the dietetics in these ills have been treated of under forced alimentation and under diet in fever.

The book contains a great amount of valuable material, based upon clinical experience extending over a long period. The arrangement of the lectures is exceedingly good, which arrangement, supported by a good index, makes the searching for a certain diet an easy matter, and assists in the enjoyment of the reading of the book.

Attached to the book are Hints for Dietetic Cooking, by Miss Hannemann, a well known author in this field. As the book is written for physicians, the introduction the author gives to her hints is very practical. She explains specific cooking expressions which are so foreign to every one not connected with the kitchen. The hints contain a rich store of good recipes under well arranged headings.

*Practice of Medicine for Nurses.* A Textbook for Nurses and Students of Domestic Science, and a Handbook for all Those Who Care for the Sick. By GEORGE HOWARD HOXIE, A. M., M. D., Professor of Internal Medicine in the University of Kansas, etc. With a Chapter on the Technique of Nursing, by PEARL L. LAPTAD, Principal of the Training School for Nurses of the University of Kansas. Philadelphia and London: W. B. Saunders Company, 1908. Pp. 284.

As the title indicates, the purpose of this book is to provide a manual for those who care for the sick, either as a professionally educated nurse or as a voluntary home Samaritan. The book gives such information as is most helpful in following the directions of the attending physician.

It contains three introductory chapters, and the subsequent matter is divided into thirty-nine chapters, each treating of a couplet of diseases or one disease alone, such as typhoid fever (chapter iv), pneumonia (chapter v), scarlet fever (chapter vi), blood poisoning (chapter xvi), coughs and colds (chapter xx), blood disorders (chapter xxiv), diseases of the eye (chapters xxxv and xxxvi), etc.

Miss Laptad has written an interesting chapter on the care of patient and the sick room; while

emergencies, such as acute poisoning and antidotes, etc., are dealt with in the last chapter.

The book should find its place on every mother's table, as it contains many a valuable hint, and a physician can well recommend it to the families whose medical cares are placed in his hands. But why introduce such a book with such an illustration as is given in Fig. 1, opposite the title page?

*Woman. A Treatise on the Normal and Pathological Emotions of Feminine Love.* By BERNARD S. TALMEY, M. D., Gynecologist to the Yorkville Hospital and Dispensary, etc., New York. For Physicians and Students of Medicine and Jurisprudence. With Twenty-three Drawings in the Text. Second, Enlarged and Improved Edition. New York: Practitioners' Publishing Company, 1908. Pp. 258.

This second edition appears only a few months after the book came out for the first time. We reviewed it thoroughly (see the *New York Medical Journal*, lxxxv, p. 286), and to that notice we refer our readers. The new edition has been somewhat enlarged.

*The Correction of Featural Imperfections.* By CHARLES C. MILLER, M. D. Chicago: Published by the Author, 1907. Pp. 134.

The usual textbooks on surgery find but little space for cosmetic operations, and yet the distress that is caused, both in men and in women, by imperfections in feature—a distress that may influence greatly the life of the individual—makes some guide for operative procedures to remedy such conditions a desideratum. The operations are described briefly and illustrated by cuts, and the little volume may be of use to many surgeons.

*Atlas der pathologisch-anatomischen Sektionstechnik.* Von Prof. Dr. M. WESTENHÖFFER. Mit 34 Abbildungen. Berlin: August Hirschwald, 1908. Pp. 53.

The many forms and modes of procedure in post mortem examinations as taught at the German universities have induced Professor Westenhoeffer to place before his confrères a guide for necropsies which could be generally accepted. Over thirty years ago (in 1875) Virchow wrote a manual on autopsies for the Prussian coroners' physicians, to make the proceedings and their reports uniform, an English translation of which appeared from the fourth German edition in 1885. Johann Orth, who now occupies Virchow's chair as professor of pathology in the Berlin University, published a similar compendium in 1905.

Our author has founded his rules upon a topographical anatomical basis, and treats the subject in a very condensed, scientific way, illustrating his text with well executed drawings. The language is plain and to the point, and Professor Westenhoeffer avoids the complicated sentences with which the English reader so often has to struggle in German medical books.

*Bericht über den VII. internationalen Kongress für Hygiene und Demographie.* Berlin, 23-29. September 1907. Band 1. Berlin: August Hirschfeld, 1908. Pp. 304.

This is the first volume of the Report of the Fourteenth International Congress of Hygiene and Demography, held in Berlin, September 23 to 29, 1907. It is interesting to note that the contents of

the book pertaining to official proceedings appear in three languages, German, French, and English, while the papers and speeches are given in the language in which they were presented.

The book contains the reports on the organization of the congress and on the plenary meeting, the protocol of the session of the permanent international commission of the congress, and also a list of the members. Of essays there appear three: Chantemesse, Sérothérapie de la fièvre typhoïde; Haldane, Some Recent Investigations in the Hygiene and Subterranean and Subaqueous Work; and Schattenfroth, Die Grundlagen der hygienischen Wasserbegutachtung. We are to expect three more volumes.

*Transactions of the American Gynecological Society.* Volume xxxii. For the Year 1907. Philadelphia: W. J. Dornan, Printer. Pp. 568.

This volume of transactions is more portly than usual, owing to the addition of a number of papers by members of the American Surgical Society and American Ophthalmological Society in the "symposia" in which these kindred societies were especially interested.

The same high quality which has characterized the work of this society from the beginning is observable in this volume. The scope of its work, as intimated above, is broader than in any previous year.

A number of the papers are very brief, and this is a decided improvement upon earlier custom. There are very few subjects which cannot be treated in this busy age, with its superabundant literature, with comprehensive brevity. The art of luminous and informing writing is at its best when controlled by terseness and condensation, notwithstanding some noteworthy exceptions to this rule in very high places.

*Die Schuppenflechte (Psoriasis vulgaris) und ihre Behandlung.* Von Dr. S. JESSNER, Königsberg i. Pr. Zweite Auflage. Würzburg: A. Stuber, 1908. Pp. 39. (Price, 0.70 mark.)

This little pamphlet is the second edition of No. 13 of Dr. Jessner's collection of dermatological hints for the general practitioner, in which the author speaks of psoriasis vulgaris. Like all Dr. Jessner's handbooks, it contains many valuable hints and a number of good prescriptions.

*Cancer. Relief of Pain and Possible Cure.* By SKENE KEITH, M. B., F. R. C. S., Ed., Author of *Introduction to the Treatment of Disease by Radiation*, and GEORGE F. KEITH, M. B., C. M., Author of *1400 Cases of Abdominal Surgery*, with Mr. Skene Keith. New York: The Macmillan Company, 1908. Pp. 188. (Price, \$1.35.)

This volume is offered as a contribution of five years' experiments in the treatment of cancer by means of an injection method. An emulsion is made of iodipin, iron arsenate, mann calcium, and sodium cinnamate, which is given in doses of from two to five cubic centimetres every other day. There are records of thirty-six cases of carcinoma and five of sarcoma; these histories are not so detailed as might be wished, and they are not summarized. While the authors state that in many cases there was relief of pain, further data are necessary to indicate the value of the preparation as a cure.

## BOOKS, PAMPHLETS, ETC., RECEIVED

The Sexual Question. A Scientific, Psychological, Hygienic, and Sociological Study for the Cultured Classes. By August Forel, M. D., Ph. D., LL. D., Formerly Professor of Psychiatry at and Director of the Insane Asylum in Zurich (Switzerland). English Adaptation by C. F. Marshall, M. D., F. R. C. S., late Assistant Surgeon to the Hospital for Diseases of the Skin, London. Illustrated. New York: Rebman Company, 1908. Pp. 536.

Transactions of the American Paediatric Society. Nineteenth Session. Held at the Arlington Hotel, Washington, D. C., May 7, 8, and 9, 1907. Edited by Linnaeus Edford La Fetra, M. D. Volume xix. New York: E. B. Treat & Co., 1908. Pp. 220.

---

 Miscellany.
 

---

**The Medical Centre of the World.**—Dr. Osler in his letter from Vienna in the *Journal of the American Medical Association* remarks:

As a medical centre Vienna has had a remarkable career and her influence, particularly on American medicine, has been very great. What was known as the first Vienna school in the eighteenth century was really a transference by van Swieten of the school of Boerhaave from Leyden. The new Vienna school, which we know, dates from Rokitsansky and Skoda, who really made Vienna the successor of the great Paris school of the early days of the nineteenth century. But Vienna's influence on American medicine has not been so much through Skoda and Rokitsansky as through the group of brilliant specialists—Hebra, Sigismund, and Neumann in dermatology; Arlt and Jaeger in ophthalmology; Schnitzler and von Schrötter in laryngology; Gruber and Politzer in otology. These are the men who have been more than others responsible for the successful development of these specialties in the United States. Austria may well be proud of what Vienna's school has done for the world, and she still maintains a great reputation, though it can not be denied, I think, that the Æsculapian centre has moved from the Danube to the Spree. But this is what has happened in all ages. Minerva Medica has never had her chief temples in any one country for more than a generation or two. For a long period at the Renaissance she dwelt in northern Italy, and from all parts of the world men flocked to Padua and to Bologna. Then for some reason of her own she went to Holland, where she set up her chief temple at Leyden with Boerhaave as her high priest. Uncertain for a time, she stayed here with Boerhaave's pupils, van Swieten and de Haen, and could she have come to terms about a temple, she doubtless would have stayed permanently in London, where she found in John Hunter a great high priest. In the first four decades of the nineteenth century she lived in France, where she built a glorious temple to which all flocked. Why she left Paris, who can say? But suddenly she appeared here, and Rokitsansky and Skoda rebuilt for her the temple of the new Vienna school, but she did not stay long. She had never settled in northern Germany, for though she loves art and science she hates with a deadly hatred philosophy and all philosophical systems applied to her favorite study. Her stately Grecian shrines, her beautiful Alexandrian home, her noble Roman disciples did she move to Germany, where she stays in Johannes Müller and in Rudolph Virchow true and loyal disciples did she move to Germany, where she stays in spite of the tempting offers from France, from Italy, from England, and from Austria.

In an interview most graciously granted to me, as a votary of long standing, she expressed herself very well satisfied with her present home, where she has much honor and is everywhere appreciated. I boldly suggested that it was perhaps time to think of crossing the Atlantic and setting up her temple in the new world for a generation or two. I spoke of the many advantages, of the absence of tradition—here she visibly weakened, as she has suffered so much from this poison—the greater freedom, the enthusiasm, and then I spoke of missionary work. At these words she turned on me sharply and said: "That is not for me. We gods have but one motto—those that honor us we honor. Give me the temples, give me the priests, give me

the true worship, the old Hippocratic service of the art and of the science of ministering to man, and I will come. By the eternal laws under which we gods live I would have to come. I did not wish to leave Paris, where I was so happy and where I was served so faithfully by Bichat, by Laennec, and by Louis"—and tears filled her eyes and her voice trembled with emotion—"but where the worshippers are the most devoted, not mark you, where they are the most numerous; where the clouds of incense rise highest, there must my chief temple be, and to it from all quarters will the faithful flock. As it was in Greece, in Alexandria, in Rome, in northern Italy, in France, so it is now in Germany, and so it may be in the new world I long to see." Doubtless she will come, but not until the present crude organization of our medical clinics is changed, not until there is a fuller realization of internal medicine as a science as well as an art.

**The White Man in the Tropics.**—Anderson observes that when a species is well adapted to the conditions which environ it, it flourishes; when imperfectly adapted, it decays; when ill adapted, it becomes extinct. When a white man, native of a temperate zone, goes to the tropics, there occurs a biological reaction of his system to the new environment, and a readjustment of coordination between his vital processes. In the tropics, the white man, individually, can exist; racially, he cannot persist. Acclimatization is not possible. No superior race can successfully govern an inferior race, superior in numbers, with equality before the law. Only by partial enslavement of the colored natives, superior in numbers, can the white man rule and govern the tropics, and it is only by relays of fresh representatives he can continue his sovereignty. No colony of northern origin has ever been able to lead a permanent and independent existence in the tropics.—*The Journal of the American Medical Association*.

**The Millwheel.**—At the dinner of the Edinburgh branch of the British Medical Association Dr. Charles Kennedy delighted the company with the following original song:

*Tune*—The Millwheel.

My opsonic index is negative,  
I greatly fear I must die,  
I often require a restorative  
Of Scotch or Irish or rye;  
My leucocytes are not digestive  
Of staphylococci.

I've a boil no bigger than half a crown,  
Though it feels as big as a score,  
It makes me sit up when I try to sit down,  
It is so devilish sore;  
It's hotter than hell, and I've tried to drown  
My sorrows in nips galore.

A bacteriologist came one day  
With sterilized lancet and all,  
He pricked it, and he carried away  
Some matter from that boil;  
A little matter, I heard him say,  
To grow on another soil.

He planted it in a jelly dish,  
It flourished under his eye;  
Said he, when I asked him, "What is this?"  
"They're staphylococci!"  
Yes, yes," he murmured, "What more can one wish  
Than staphylococci!"

My germs, in strange serum, with nicely washed leucocytes he now incubated,  
And with oil immersion lens brought into view  
The fact that each polymorph fed  
On three or four cocci, and so one drew  
An index opsonic, he said.

Then serum from me, for his leucos he asked,  
A meal of my germs to prepare;  
But they smiled at him, as in sunshine they basked,  
For not one opsonin was there!  
The cocci smiled blandly as polymorphs passed  
With stolid, ameboid stare!

With the ghost of a chuckle, he gazed on the sight,  
Then took up a Pravaz syringe  
To dose me with cocci cream cooked à la Wright,  
And told me my welfare would hinge  
On whether my leucocytes still took fright  
At cocci of golden tinge.

My wretched opsonins will not revive!  
No matter how often we try;  
The boil is much better, but can I survive  
If the man with the cocci reply,  
"You can only get well, if your leucocytes thrive  
On staphylococci!"

And now, I could do with a drop of Scotch,  
I like it much better than hy-  
Podermic injections of coecal hotch potch,  
And fain with my boil would I fly  
To regions obscure, where there's no one to tort-  
Ure me with pickled cocci.

### Public Health and Marine Hospital Service:

Official list of changes in the stations and duties of commissioned and noncommissioned officers of the United States Public Health and Marine Hospital Service for the fourteen days ending June 3, 1908:

- BELL, J. M., Pharmacist. Granted leave of absence for five days, from May 19, 1908, under paragraph 210, Service Regulations.
- CARTER, P. I., Acting Assistant Surgeon. Granted leave of absence for three days, from May 19, 1908, under paragraph 210, Service Regulations.
- CLEAVES, F. H., Acting Assistant Surgeon. Granted leave of absence for ten days, from May 26, 1908.
- COBB, J. O., Surgeon. Granted leave of absence for seven days.
- EICHELBERGER, W. W., Acting Assistant Surgeon. Granted leave of absence for fifteen days, from June 10, 1908.
- FAHEY, E. W., Acting Assistant Surgeon. Granted leave of absence for ten days, from May 26, 1908.
- GARDNER, C. H., Passed Assistant Surgeon. Granted leave of absence for one month, from May 31, 1908.
- HOLT, J. M., Passed Assistant Surgeon. Granted leave of absence for five days, from June 2, 1908.
- HUNT, REID, Chief of Division of Pharmacology. Detailed to attend the Council of Pharmacology and Chemistry, in Chicago, Ill., June 2, 1908, upon the completion of which duty to rejoin his station.
- HUNTER, W. R., Acting Assistant Surgeon. Granted leave of absence for four days, from June 4, 1908.
- KEATLEY, H. W., Acting Assistant Surgeon. Granted leave of absence for three days, from May 13, 1908, on account of sickness.
- KING, W. P., Passed Assistant Surgeon. Relieved from duty at San Francisco, Quarantine station, and directed to report to the medical officer in command of the Marine Hospital at San Francisco, for duty and assignment to quarters.
- NAULTY, C. W., Jr., Acting Assistant Surgeon. Granted leave of absence for five days, from June 17, 1908.
- PEARSE, H. E., Acting Assistant Surgeon. Granted leave of absence for three months without pay, from June 15, 1908.
- ROBERTS, NORMAN, Assistant Surgeon. Granted leave of absence for three days, from May 15, 1908, under paragraph 101, Service Regulations. Granted leave of absence for one month, from June 1, 1908.
- ROSENAU, M. J., Surgeon. Granted leave of absence for one month.
- SMITH, A. C., Surgeon. Granted leave of absence for one month and fifteen days, from July 1, 1908.
- THORNTON, M. J., Acting Assistant Surgeon. Granted leave of absence for one month, from June 1, 1908.
- TRASK, J. W., Passed Assistant Surgeon. Granted leave of absence for five days, from June 6, 1908.

- WAKEFIELD, H. C., Acting Assistant Surgeon. Granted leave of absence for five days, from May 21, 1908, under paragraph 210, Service Regulations.
- WHITE, M. J., Passed Assistant Surgeon. Granted leave of absence for one month, from June 1, 1908.
- YOUNG, G. B., Surgeon. Detailed to attend the meeting of the Lake Michigan Water Commission, at Grand Rapids, Mich., May 27, 1908.

#### Appointment.

Dr. Nathanael L. A. K. Slambert appointed as Acting Assistant Surgeon, for duty at Eastport, Idaho.

### Army Intelligence:

*Official list of changes in the stations and duties of officers of the medical corps of the United States Army for the week ending June 6, 1908:*

- ASHFORD, B. K., Captain. When no longer needed at Hattiesburg, Miss., ordered to return to Washington Barracks.
- BAILY, H. H., Captain. When no longer needed at Hattiesburg, Miss., ordered to return to Washington Barracks; returned to Fort Myer, Va., from detached service at Hattiesburg, Miss.
- BANISTER, J. M., Lieutenant Colonel. Appointed a member of a board of review to meet at Washington, D. C., to review proceedings and findings of medical examining boards in the case of medical officers found disqualified for promotion.
- CRAMPTON, L. W., Colonel. Appointed a member of a board of review to meet at Washington, D. C., to review proceedings and findings of medical examining boards in the case of medical officers found disqualified for promotion.
- EBERT, R. G., Major. Ordered to Vancouver Barracks, Wash., for duty as chief surgeon, Department of the Columbia.
- HUTTON, P. C., Captain. Ordered to return to Fort William H. Seward, Alaska, from Fort Benjamin Harrison, Ind.
- LA GARDE, L. A., Lieutenant Colonel. Granted an extension of his leave of absence to include June 24th; appointed a member of a board of review to meet at Washington, D. C., to review proceedings and findings of medical examining boards in the case of medical officers found disqualified for promotion.
- LYNCH, CHARLES, Major. Ordered to temporary duty in the surgeon general's office, and on its completion to revert to status of leave.
- MUNSON, E. L., Major. Granted leave of absence for one month.
- REYNOLDS, C. R., Captain. Arrived in New York from the Philippines Division, on leave of absence.
- STONE, J. H., Major. Relieved from duty with the Army of Cuban Pacification, and ordered to Newport News, Va., for further orders.
- STRAUB, P. F., Major. Ordered to report to the President of the Army War College for duty pertaining to the staff ride over the battlefields of Virginia.
- TORNEY, G. H., Colonel. Granted leave of absence for fifteen days.

### Navy Intelligence:

*Official list of changes in the stations and duties of officers of the medical corps of the United States Navy for the week ending June 6, 1908.*

- ALLEN, A. H., Assistant Surgeon. Detached from duty in connection with the Cape Cruz-Casilda survey expedition and ordered to duty with the Marines at Havana, Cuba.
- BIELLO, J. A., Assistant Surgeon. Detached from the Naval Hospital, Portsmouth, N. H., and ordered to the *Salace*.
- BISHOP, L. W., Passed Assistant Surgeon. Detached from the *Hancock* and ordered to the Naval Recruiting Station, Indianapolis, Ind.
- BREWER, E. M., Assistant Surgeon. Detached from the Naval Hospital, Puget Sound, Wash., and ordered to continue other duties.
- COOK, F. C., Surgeon. Detached from the Naval Academy, and ordered to the *North Carolina*, June 6, 1908.
- HOLEMAN, C. J., Assistant Surgeon. Orders of May 26th modified; detached from the Naval Training Station, San Francisco, Cal., and ordered to the *Arethusa*.

- MCDONELL, W. N., Passed Assistant Surgeon. Detached from the Naval Recruiting Station, Buffalo, N. Y., and ordered to the *Severn*, for duty in connection with the Navy Rifle Team.
- SCHALLER, W. F., Assistant Surgeon. Resignation accepted, to take effect June 1, 1908.
- SMITH, C. G., Passed Assistant Surgeon. Ordered to the Naval Hospital, Portsmouth, N. H.
- WHITE, E. C., Assistant Surgeon. Detached from duty with Marines at Havana, Cuba, and ordered home to wait orders.

## Births, Marriages, and Deaths.

### Born.

- BRECHEMIN.—In Fort McKinley, Philippine Islands, on Tuesday, March 17th, to Dr. Louis Brechemin, Jr., Medical Corps, United States Army, and Mrs. Brechemin, a son.
- ELLIOTT.—In Philadelphia, on Tuesday, June 2d, to Dr. John Dean Elliott and Mrs. Elliott, a daughter.
- GILLESPIE.—In New York, on Sunday, May 24th, to Dr. H. M. Gillespie and Mrs. Gillespie, a daughter.

### Married.

- ALEXANDER—MALTY.—In New York, on Saturday, June 6th, Mr. Ludwell T. Alexander, son of Dr. Welcome T. Alexander, and Miss Mary Breckenridge Maltby.
- DUNLOP—SCHAFFER.—In Washington, D. C., on Tuesday, June 2d, Dr. John Dunlop and Miss Gertrude King Schuyler Schaeffer.
- FLOWERS—ROSE.—In Harrisburg, Pennsylvania, on Tuesday, June 2d, Dr. Claude J. B. Flowers and Miss Augusta Karoline Frederica Rose.
- GILBERT—STAMPER.—In Cincinnati, Ohio, on Thursday, May 28th, Dr. J. T. Gilbert and Miss Blanche Stamper.
- HAZEN—ROSS.—In Malden, Massachusetts, on Monday, June 1st, Dr. Henry Honeyman Hazen and Miss Laura May Ross.
- MILLER—FOLTZ.—In Harrisburg, Pennsylvania, on Tuesday, June 2d, Dr. David I. Miller and Miss Mary Frances Foltz.
- SWAYNE—PARAMORE.—In Philadelphia, on Wednesday, June 3d, Dr. Eugene Swayne and Miss Ida M. Paramore.
- THOMPSON—NAGLE.—In Philadelphia, on Monday, June 1st, Dr. Louis L. Thompson and Miss Elsie May Nagle.
- VAN WORT—DIXON.—In Brooklyn, New York, on Tuesday, June 2d, Dr. Clarence Thorn Van Wort and Miss Mary Louise Dixon.
- WHITE—WILLIAMS.—In Alexandria, Virginia, on Monday, June 1st, Dr. W. E. White, of Harrisburg, Pennsylvania, and Dr. Mary B. Williams.
- WINSMORE—BUHRE.—In Philadelphia, on Tuesday, June 2d, Dr. Henry Davis Winsmore and Miss Bell Buhre.

### Died.

- BELL.—In Omaha, Nebraska, on Thursday, May 28th, Dr. Joseph Bell, aged sixty-five years.
- CATE.—In Medford, Massachusetts, on Thursday, May 28th, Dr. Isaac Wallace Cate.
- CHRISTIE.—In Omaha, Nebraska, on Thursday, May 28th, Dr. William H. Christie, aged sixty-four years.
- CULBERTSON.—In Cincinnati, Ohio, on Thursday, June 4th, Dr. J. C. Culbertson, aged seventy-five years.
- DEANE.—In Montague Centre, Massachusetts, on Sunday, May 31st, Dr. Ebenezer A. Deane, aged eighty-three years.
- FOSTER.—In Concord, New Hampshire, on Saturday, June 6th, Mr. William P. Foster, father of Dr. Frank P. Foster, of New York, aged ninety years.
- IRISH.—In Lowell, Massachusetts, on Friday, May 29th, Dr. John Carroll Irish, aged sixty-five years.
- MILLER.—In Camden, Maine, on Friday, May 29th, Dr. Horace George Miller, aged sixty-eight years.
- RONAN.—In Albany, New York, on Monday, May 25th, Dr. Andrew J. Ronan.
- SCHADLE.—In St. Paul, Minnesota, on Friday, May 29th, Dr. Jacob E. Schadle, aged fifty-nine years.
- TABER.—In Elmira, New York, Friday, May 29th, Dr. Alfred B. Taber, aged seventy-six years.

#### A NEW METHOD OF ESTIMATING THE PERMEABILITY OF THE PYLORUS AND AN ATTEMPT AT TESTING THE PANCREATIC FUNCTION DIRECTLY.\*

By MAX EINHORN, M. D.,

New York,

Professor of Internal Medicine at the Postgraduate Medical School.

##### *I.—Permeability of the Pylorus.*

The methods ordinarily used for estimating the permeability of the pylorus are based principally upon examinations of the motor function, or rather prochoresis, of the stomach, as, for instance, the oil test of Klemperer and the examination for food remnants of the day previous in the fasting condition. Neither test decides whether the trouble is caused by abnormal weakness of the gastric musculature or by a narrowing of the pylorus. The rice test meal recommended by myself and the currant test of Strauss take the condition of the

and the currant test suffers from the drawback that frequently the currants will not pass the stomach tube.

The direct introduction of rubber tubes into the pylorus has been tried by Hemmeter and Kuhn, but not with very marked success.

The idea presented itself of having beads of dif-

The permeability of the pylorus was estimated in a series of experiments on patients who had been kept in patient McK.'s digestive tract for five and a half hours. The results are summarized and given in the table on opposite page.

pylorus a little more into account. The rice test will, however, be positive only in advanced cases.

\*Read before the meeting of the Chicago Association of Surgeons, Chicago, Ill., on June 1, 1908.

been kept in patient McK.'s digestive tract for five and a half hours. The results are summarized and given in the table on opposite page.

ferent sizes attached to a silk thread and having them swallowed in order to see whether they pass the pylorus or not. In normal conditions they will pass; in stenosis they will remain in the stomach. As the length of the thread in itself is not a sufficient guide to decide whether the bead was in the duodenum or not we must look for a different indicator for this purpose. In the beginning I used beads coated with mutton tallow, later beads filled with methylene blue and coated with mutton tallow. In as far as the fat is dissolved mainly in the duodenum, a green or blue color of the urine would show that the bead had already passed the pylorus. This usually occurs in from three to five hours. If we then withdraw the tube we will find that it is empty, i. e., contains neither fat nor methylene blue. In order to be sure, however, that the green color (disappearance of fat and methylene blue) really occurred in the duodenum and not in the

FIG. 3.—Section of a thymus piece (proximal piece), which had been kept in patient O.'s stomach for six hours (April 29, 1908). The nuclei are visible as rounded or slightly oval bodies of a regular shape.

stomach, I tied another similar bead for control purposes to the thread at a distance of fifty centimetres from the lips. This bead can only remain in the stomach, whereas the original bead was tied at a distance of seventy-five centimetres from the lips, and could thus pass the pylorus and travel for a distance in the duodenum. If, therefore, the distant bead is empty, whereas the proximal bead is still filled, it would prove that the lower bead had passed the pylorus.

In some cases of pyloric stenosis both beads remained full.

In doing this test on a large number of patients without pyloric stenosis at the German Hospital, it was shown that frequently the stomach bead was empty, i. e., the fat can disappear from the bead in the stomach (perhaps mechanically), and methylene blue can thus be liberated. If both beads

are empty we can naturally not say whether the lower bead passed the pylorus or not.

It was therefore necessary to look for other indicators. At first I used pieces of thymus in gauze and tied to the bead. In the small intestine the nuclei will disappear, whereas in the stomach they are not changed. If we allow the beads with the thymus for four to six hours to remain in the digestive tract, we find in most cases that the result will be as indicated before. (See Figs. 1 to 4.)<sup>1</sup> If, however, we leave the beads in the intestinal tract for a longer time, as over night (for about eleven to twelve hours), it happens occasionally that the nuclei will also disappear in the stomach.

FIG. 4.—Section of a piece of thymus (distal piece), which had been kept in patient O.'s digestive tract for six hours (April 26, 1908). The nuclei are partly destroyed. In some places they show distinctly irregular shapes.

Why this should happen, whether there is regurgitation of the pancreatic juice into the stomach, or whether it is due to other circumstances, I am at present unable to state. At all events, the thymus was not sufficiently reliable for our purpose.

Instead of thymus I used pieces of agar that had been saturated with tincture of litmus and later with dimethyl-amidoazobenzol. They were placed in gauze and tied to the beads. By means of the litmus agar we determined that the duodenal juice (or duodenal chyme) is usually acid, because the distal agar pieces were colored red just like the proximal stomachpieces.

<sup>1</sup>I am greatly indebted to Miss Katharine Foot and Miss E. C. Strobell for taking these excellent micro-

The dimethylagar, however, proved useful. It was colored red in the stomach if it was removed at a time when free hydrochloric acid was present, whereas the duodenal piece usually remained colorless. It may, of course, occur that the proximal piece also remains uncolored, particularly in cases of achylia or marked subacidity; on the other hand, the duodenal piece may be red, if it has not remained long enough in the duodenum to lose its color, or where the duodenal chyme, for some distance, still contains free hydrochloric acid. In these cases the test has to be done with a different indicator.

It would be advisable to always use two indicators at the same time, as, for instance, fat and dimethyl or fat and thymus, in order to decide more accurately.

For in all cases in which one of the indicators shows a difference between stomach and duodenum, we can be sure that the lower bead has passed the pylorus.

## II.—Testing the Pancreatic Function.

Examination of the *faeces* has up till now furnished the best means for judging the pancreatic function. The nuclein test of Schmidt seems thus far to be the best procedure. The disadvantage, however, lies in the fact that at least twenty-four hours are needed for the completion of the test; secondly, that if they disappear later the possibility of their destruction by microorganisms cannot be excluded.

I have already mentioned that pieces of thymus attached to the thread and swallowed lose the nuclei for the greater part in the duodenum. This may, of course, be utilized for testing the pancreatic function. I proceed as described before, and have the result in five hours.

Instead of observing the change in test substances due to the action of the pancreatic juice it would naturally be better to get the juice directly. Boas tried this by introducing a tube into the empty stomach, massaging the region of the liver, and then obtaining the gastric contents. In some cases Boas succeeded in demonstrating pancreatic juice in this fluid. This method is, however, successful only in a fraction of the cases. The same may be said of the methods of Hemmeter and Kolmer to obtain the juice by direct sounding of the duodenum.

On the same principle as the stomach bucket I have constructed a much smaller duodenal bucket (Fig. 5). If we have the patient swallow the bucket on a thread for a distance of several cen-

timetres from the lips then we can often obtain duodenal chyme.

I proceed as follows: The duodenal bucket, tied to a long string of braided silk, with a mark at seventy-five centimetres, is placed in a gelatin capsule and given about one hour after a small meal. It is left in the digestive tract for three hours without taking any more food. The thread is tied to the ear or fastened in another manner, so that it cannot go beyond the seventy-five centimetre mark. After three hours the thread is slowly drawn up. In many cases we could feel a slight resistance when the bucket passed the pylorus, the cardiac end usually offering no resistance. At the entrance of

the oesophagus the resistance is overcome by having patient swallow once before withdrawing the bucket. It is still better to have patient swallow the bucket before retiring and withdraw it in the morning in the fasting condition.

I leave the bucket open a while. The contents may be removed by means of a syringe and placed in a small porcelain dish. The contents usually look yellowish (owing to the coagulum of bile) and yield a normal quantity acid reaction without the presence of free hydrochloric acid.

Only in one case of grave hyperchlorhydria, after an old ulcer of the stomach, free hydrochloric acid was found in the yellowish fluid. In this case the string showed a distinctly brownish coloration at the portion 52 to 64 cm., while the rest was not colored. The brown part gave positive reaction for blood. The colored string marked most probably the position of the ulcer in the pylorus and duodenum.

That the duodenal bucket really gets into the duodenum may be seen, first, from the contents, secondly, from a Röntgen ray picture taken before removing the bucket. Such an x ray picture from patient H., three and a half hours after swallowing

## FAVUS, WITH REPORTS OF TWO INDIGENOUS CASES.

By EMANUEL J. STOUT, M. D.,  
Philadelphia,

Associate in Dermatology in the Jefferson Medical College.

Favus (literally a honeycomb) is of rare occurrence among natives of the United States, and is usually met with in this country among the flotsam from foreign lands, notably Russia, Poland, and Italy. Both cases, to be referred to later, are examples of the disease in individuals born of American parents. Usually the affection is located on the scalp (favus capitis or tinea favosa capitis, but any

part of the body, even the mucous membranes, may be attacked. Favus of the nails, also known as onychomycosis favosa (from *ὄνυξ*, nail; and *μυκός*, a fungus) is exceedingly rare, and the fungus is, as a rule, introduced under the nail by the latter scratching the scalp. Lack of cleanliness and unfavorable hygienic surroundings are regarded as favoring its spread—one of the synonyma used by the French, *teigne du pauvre*, being quite suggestive, although the disease is occasionally seen in individuals belonging to the better class. This may be explained by the fact that tinea favosa may be transmitted by animals, such as cats, dogs, rats, mice, rabbits, fowls, cattle, and horses, and numerous cases have been recorded in which the disease has been conveyed from animals to human beings. The writer is inclined to regard barber shops and other public places, where combs and brushes<sup>1</sup> are used promiscuously, with considerable suspicion, although he cannot recall these articles being mentioned in dermatological textbooks as causative factors. Some time ago, while resting after a Turkish bath, the writer observed an Armenian rubber, employed in the establishment, who exhibited typical favus of the scalp, deliberately use the brush and comb, intended for customers, and arrange the few locks the achorian had left untouched.

Obstupui, steteruntque comæ et vox faucibus hæsit! (Vergil). Although favus has been placed on the list of contagious diseases by the United States government, and is regarded as sufficient cause for refusing admission to immigrants, nevertheless its not infrequent occurrence—principally among the foreign population—bears evidence to the fact that the supposed Argus eyed inspectors at the various immigrant stations either fail to recognize the condition or overlook it. From personal observation the

Fig. 6. X-ray picture taken three and a half hours after the above patient twenty-four hours earlier, showing the position of the colored and the duodenal bucket, which patient had swallowed about three hours previous to this exposure to the x rays. A, cæcum; B, hepatic flexure; C, splenic flexure; E, duodenal bucket. Comparing Fig. 6 with Fig. 7 it can easily be seen that the bucket is lodged beyond the stomach (duodenum).

the bucket is here reproduced. (Figs. 6, 7, and 8.)<sup>2</sup> The duodenal bucket can, of course, also be used for testing the permeability of the pylorus. For when it returns with the duodenal contents it certainly must have passed the pylorus. The tests described here, however, will be of benefit principally in those cases in which there is any doubt whether regurgitation has taken place from the duodenum into the stomach.

<sup>1</sup>Rayet, in *Dermatologia*, 1845, p. 100, states that favus is readily communicated among children who make use of the same comb and brush.

writer has been impressed with the tendency among a certain class of patients, when being treated for some cutaneous affection, to deny that they are affected with favus, although the presence of scutula and loss of hair, often associated with extensive atrophy of the skin or the scalp, will frequently point to the true character of the disease. Although much less contagious than ringworm, its appearance in public institutions, homes, and schools is much to be dreaded. This is another excellent reason why medical inspection of school children should be entrusted to competent hands only, and carried out thoroughly. How often, however, are those who are expected to make a correct diagnosis of cutaneous affections among school children unable to recognize the true state of affairs, and how frequently we meet with the stereotyped phrase on certificates, "disease of the scalp" (sic), forcibly reminding one of that other threadbare expression, "heart failure," which in former times played quite an important rôle in death certificates. Owing to its chronic character and rebelliousness to treatment, when on the scalp or affecting the nails (favus of the cutaneous surface, *tinea favosa epidermidis*, being much more amenable to treatment), it has proved a veritable *bête noire* to the dermatologist. The modern treatment of favus capitis with the x ray, strictly observing the technique and rules laid down by Sabouraud and Noiré (*La Presse médicale*, 1904, p. 825, and *Annales de dermatologie et de syphilis*, 1904, p. 80), in conjunction with local applications, has helped very materially in shortening the time required to affect a cure. Under the old method of treatment the time necessary to bring about lasting and favorable results ranged from six months to two years; now, however, it has been reduced to three months. Even under these much more favorable circumstances, "an ounce of prevention is worth more than a pound of cure" fully applies to favus.

The first case to be described bears a resemblance in some respects to the one reported in 1804 by Cantrell and Stout ("A Case of Favus of the Head and Body," *Journal of Cutaneous and Venereal Diseases*, pp. 375 and 410; article contains review of similar cases and bibliography).

CASE 1.—John L., fourteen years of age, born in New York City, came under the writer's care the latter part of July, 1907.

FAMILY HISTORY.—Both parents are living. Father is a native of Boston, mother was born in New England. Two brothers and one sister are living. According to statements made by his aunt, quite an intelligent and well-looking woman, he is the only member of the family having this eruption.

Previous History: Patient had measles and scarlatina. His aunt stated that the disease began on the scalp two years ago, while her nephew was in a home, and appeared on the body and nails six months later.

Present Condition: The lad presented an anæmic appearance, the muscles were flabby and the panniculus adiposus was poorly developed. He was 5 feet 3 inches in height, weighed 85 pounds, and had dark blue eyes and dark hair. Scrotal hernia on right side. He complained of itching on the scalp, more or less severe at times.

Examination of Urine: Reaction acid, specific gravity 1.022, no trace of albumin or sugar.

Scalp: On examination the entire scalp was found to be involved, with the exception of an area in both temporal regions about two inches wide and 3 inches long. The postauricular lymphatic glands were visibly enlarged; pediculi or ova could not be found. Innumerable scutula

FIG. 1.—Scalp of the patient, showing the typical scutula of favus. The scutula are of various sizes, and are often surrounded by a zone of erythema. The hair is often broken or falling out. The scutula are often surrounded by a zone of erythema. The hair is often broken or falling out. The scutula are often surrounded by a zone of erythema. The hair is often broken or falling out.

of various size were situated on the anterior and posterior part of the scalp; toward the temporal regions they were more or less scattered and some of the larger formed a striped concentric arrangement. When examined close than had they presented the typical cup-shaped appearance characteristic of the favus scutulum (scutulum, diminutive of scutella, a shield). These crusts, however, on their lower and convex or concave surface, had also beneath some of the small dark pits, pores, or depressions, and the pressed and under some of the depressions a granular mass was visible. The removal of the crusts of this type was accompanied by slight bleeding. A few of the smaller lesions were peculiar in shape, being rather circular, the fingers the crusts crumbled readily. Some of the more

recent favi showed the sulphur yellow color; where they had become confluent they looked brownish yellow. The characteristic odor—suggesting the odor of mice or musty

exhibited longitudinal splitting, and could be readily extracted with forceps. Midway of the scalp there were several atrophic areas, almost entirely devoid of hair, varying in size, the largest being about two inches by two inches in extent. The eruption extended anteriorly slightly beyond the hairy margin of the scalp and posteriorly about one half inch beyond the hair line. Owing to the hair being rather long, it was impossible to obtain a satisfactory photograph showing the full extent of the disease.

**Face:** Two typical, sulphur yellow, cup shaped lesions, of the size of a split pea, were visible on the face below the processus zygomaticus; one similar, smaller, lesion was situated on the upper part of the left ear and one pinpoint scutulum on the lower part of the left ear lobe, and three lesions, the size of a pea, were located near the left commissure of the lower lip, below the mucocutaneous junction.

**Nails:** The thumb nail of right hand had lost its glossy appearance and was brittle, and slightly fissured; the greater part of the nail from its distal end to lunula, and laterally from the nail fold to corresponding side, was implicated. The nails on the middle and index finger of the same hand were of a grayish yellow color and slightly raised from the nail bed. They were involved principally at the lateral and anterior margins, and only about one fourth of the nail substance appeared to be diseased.

On the left hand the nails of the thumb, index, and ring fingers were slightly affected and did not differ much in appearance from those of the right hand. The toe nails did not show any deviation from the normal.

The existence of favus on the body was discovered by accident. The writer's hand happening to come in contact with the lad's arm, and he being clad with a thin alpaca coat, the weather being quite warm, it was possible to detect decided irregularities through the coat sleeve. The patient did not refer to any eruption on the body and appeared to be anxious to conceal the exact state of affairs and merely called attention to his head and face. After considerable persuasion he allowed a thorough examination to be made, which revealed the following conditions:

**Arms:** On extensor surface of upper part of right arm there were eight scutula, varying in size from a pea to that of a quarter of a dollar. Above the external condyle the lesions had become confluent and had formed a patch, measuring about two inches in width and five inches in length, situated on the external surface of the ulna. About the middle of the elbow joint and on the internal condyle of the humerus there were present two favus cups. Numerous smaller scutula, exhibiting a tendency to become confluent, were distributed on the inner surface of the radius, and eight to ten isolated favus cups were scattered over the extensor surface of the forearm, terminating one and one half inches above the wrist.

**Left Arm:** Beginning at the acromion a patch, measuring about one inch in width at the starting point and gradually growing wider, reached about three inches downward to a point on a level with the left nipple. From this point an almost continuous sheet of scutula extended to within two inches of the left wrist.

**Trunk:** The anterior part of the chest, abdomen, and pubic region were not involved.

**Legs:** The scutula were quite plentiful on the upper part and outer margins of the thighs; a few were discrete, and some had coalesced. On the lower part of the thighs the eruption was very abundant, and extended downward, becoming narrower at the condylus externus of the femur and gradually broadening out, terminated three inches above the condylus externus of the tibia. On the inner surface of the tibia a patch, several inches in length, was situated below the knee joint. The patellæ were free from eruption, with the exception of a few isolated lesions on the left. On the left leg almost the same areas were invaded, except the anterior upper surface of the tibia. The eruption on the lower extremities showed considerable symmetry. On the left scapula were two large circinate lesions the size of fifty cent pieces, the one near the upper margin and the other about midway. Near its lower border were located one lesion, the size of a dollar, and another, the size of a quarter of a dollar, the latter becoming confluent with the former. The posterior surface of the left arm and outer margin of the left scapula were covered with abundant confluent scutula, and the entire arm from the

straw—was very pronounced. The hairs showed decided change and had lost their lustre, were dry and brittle, some

shoulder to within a few inches of the capitulum ulnæ was literally strewn with favi.

On the right arm posteriorly there was a collection of lesions, beginning about four inches below acromion and extending to a point below internal condyle of the humerus. A large patch was situated below the olecranon and on the outer margin of the forearm, and a number of isolated scutula were visible on the inner margin of the arm.

Near the waist line on the left side of the spinal column a large scutulum, the size of a quarter of a dollar, presented, and a pea sized favus cup was situated in right lumbar region. Two larger lesions, about one inch by one and one half inches in size, were noticeable in left lumbar region, near upper margin of the pelvis.

**Gluteal Region:** The left buttock was covered with the eruption, and only a few small areas remained intact; the right gluteal region was similarly affected, although in a lesser degree. The eruption on the thighs was continuous with that on the buttocks and covered large areas; the popliteal spaces showed only a few scattered favi. The posterior parts of both legs were the seat of a large number of patches and discrete scutula, the eruption being especially abundant on the left leg.

The smaller scutula exhibited the cup shape very typically; where the favus cups had become confluent, they bore a resemblance to fungi as seen on decaying stumps. Quite a number of the larger lesions were arranged in concentric rings. Where the scutula had been removed accidentally, distinct atrophy was noticeable.

The boy remained under the writer's care for six weeks, and after four weeks' treatment the lesions on the face and body had entirely disappeared. Numerous atrophic areas scattered over different parts of the body remained. The patient complained of itching, more or less severe at times, and owing to the skin being tense over the articulations and gluteal regions, movements of the body gave rise to considerable pain.

Although favus over a limited space does not affect the general health, generalized favus undoubtedly has a depressing effect on the system. It is interesting to note that the patient gained ten pounds in weight after the disappearance of the eruption and that his general physical condition improved very materially.

The time required for the eruption of favus to make its advent after experimental inoculations appears to vary somewhat. Thus in Van Harlingen's experiment upon his left arm a scutulum developed after ten days. Bulley observed favus cups appear on forearm after nineteen days, and they were preceded by an erythematous circle and herpetic lesions. In Bulkley's case three or four scutula showed on the arm of one of his assistants after six weeks, and were surrounded by a scaly, erythematous halo. Peyritsch observed favi four days after experimental inoculation and in another instance after four weeks. Wishing to make personal observations and to study the evolution of the scutula, the writer secured two mice and rubbed particles of favus crust on the temporal region. The first attempt resulted in disappointment, and proved negative after a period of five weeks had elapsed. A second effort proved successful. Following as nearly as possible Bulkley's method, several drops of water, in which particles of favus crusts had been soaked for several hours, were deposited in the temporal regions of both mice, after the skin had been scarified. Four weeks later three to four pinhead sized scutula had developed in one mouse at the site of the inoculation. It was possible to observe the presence of small vesicles, arranged in the form of

were noticeable before the scutula appeared. The skin in the temporal region of the other mouse did

FIGURE 1.—Favus after four weeks' treatment in experiment.

not show any change with the exception of slight swelling.

Report of Dr. R. C. Rosenberger, assistant professor of bacteriology, Jefferson Medical College:

Specimen, sent by Dr. Stout, consisted of crusts from the scalp, face, arms, legs, and scrapings from the finger nails. Some of these were treated with a ten per cent. solution of caustic soda and examined immediately; others were inoculated upon culture media, as bouillon and agar.

The crusts, treated with this solution, showed the characteristic hyphæ and spores of the achorion, and the scrapings from the finger nails also contained the fungus.

The inoculations upon agar and bouillon developed a mixed growth, consisting of the *Micrococcus pyogenes aureus* and mould fungus. (Inoculation of white mice was intended, but had to be abandoned, as no white mice were procurable at the time.)

From the appearance of the hyphæ, the arrangement of the hyphæ and spores, as well as the morphology of the growth upon culture media, it seemed beyond doubt that the parasite was the one recognized as the cause of favus, the *Achorion Schoenleinii*.

FIG. 3.—*Achorion Schoenleinii*: a, spores; b, hyphæ

The second case to be reported, briefly, furnishes an example of favus occurring upon the body surface alone.

CASE II.—J. R., a young girl, aged thirteen, the daughter of respectable and intelligent parents, both Americans, came to the writer's office during the summer of 1907. The parents consulted the author for an eruption on the arm of three weeks' duration and slightly itching in character. They stated that their family consisted of two children, one boy and one girl, and that no other member of the household had any cutaneous disease.

On inspection a group of sulphur yellow scutula, about ten to twelve in number, varying in size from a pinhead to that of a split pea, were seen on the flexor surface of the right forearm, three inches above the wrist joint, and occupying an area about four inches in diameter. Viewed through a lens they appeared to be located around fine lanugo hairs and were surrounded by a slight erythematous halo. The most careful search failed to elicit the presence of favus on the scalp or on any other part of the body. Bearing in mind the possibility of the disease being conveyed by animals, the writer after careful questioning elicited the information that a pet cat, belonging to the family and with which their daughter played quite frequently, had several patches on its body devoid of hair, and concluded that in all probability the cat had transmitted the disease to the girl. Microscopical examination showed the *Achorion Schoenleinii* to be present in scrapings taken from the arm.

## THE TREATMENT OF INFANTILE PARALYSIS.\*

BY CARL R. KEPPLER, M. D.,  
New York,

Orthopædic Surgeon to the Out Patient Department of Harlem and Fordham Hospital; Associate Orthopædic Surgeon, Red Cross Hospital.

Since it was the misfortune of the children population of New York and its near vicinity to have gone through a severe epidemic of anterior poliomyelitis during the last year, general interest in this disease has been greatly awakened. Infantile paralysis, which until then, on account of its comparative rarity, was observed and treated only by a selected few, now became a menace, and the cry for further information as to its ætiology, pathology, and treatment has been a universal one both in the medical and lay press.

It will be my endeavor to rapidly outline the treatment of the condition following the acute attack; but before doing so I wish to emphasize our present general opinion, that during the first six weeks all of these cases should be left alone, being kept absolutely quiet in the recumbent position. This is done so as to allow all inflammation and congestion in the spinal cord to disappear; the products of disease to become absorbed. The best means at our command for this purpose is a light, portable gas-pipe frame, to which the child is attached by an apron; this allows, without disturbance, easy transportation from room to room, or outside into the fresh air. The food administered should be light and nourishing; the child's general health carefully observed. Over the spine itself counterirritation by means of the cautery might be practised at intervals, and the limbs kept straight and warm in flannel bandages.

Passing over to the treatment of the chronic stage, that is, of established paralysis, a different phase presents itself. It is our duty now to help Nature in its reparative efforts, both at the seat of the disease as well as in the affected limbs, to prevent these efforts from becoming vicious in effect, and to gradually teach the child in protective apparatus the lost art of locomotion. An absolutely paralyzed muscle can probably not come to life again, it is true, but much can be done to strengthen those partially paralyzed or frequently only weakened. I believe, directed by observations of results obtained, that the treatment should be one of active assistance, not only of passive indifference.

The procedures to be employed I will therefore categorize as: 1, active treatment; a, by the use of pendulum machines; b, by the use of massage and electricity; c, by the use of hydrotherapy; 2, brace treatment; 3, operative treatment.

1, a, *Treatment by the Use of the Pendulum Machines*.—After the acute attack the lower (distal) part of the body is cut off from the brain by means of the changes in the spinal cord; the centres in the brain therefore not having to work any more, that is, to send out controlling impulses to these parts, return in a sense to their infant stage, in so far as to forget to frame and send out these complex impulses. But at the diseased area of the spinal cord not all—in fact, generally, not even the major

\*Read before the Medical Society of the County of Richmond, N. Y., March 11, 1908.

FIG. 1.—Pendulum machine.

portion—of the nerve tissue is absolutely degenerated, as one might be led to believe from the changes in the limbs. Many of the cells are still patent, having been simply put out of action and dormant following the intense acute inflammation of the affected area. If now we passively and rhythmically move the paralyzed limbs, using for this the basic principle of all motion, that is, the pendulum movement or swing, we send at equal intervals new impulses to the controlling brain centres—both through the medium of the still existing nerve filaments in the spinal cord, as well as through the medium of the child's eyes. The brain is thus called into activity and starts to imitate these simple pendulum movements; the impulses thus generated pass down to (and through) the partly degenerated, partly latent area in the spinal cord, causing renewed activity in the latter and possibly some regeneration in the former. All this time the effect of motion in the affected muscles of the limbs being exercised, is active in two ways: Firstly, from here impulses pass up through the peripheral nerves to their centres along the cord; these active impulses meet and mutually aid those coming from the brain, causing a two fold activity of repair in the diseased area. Secondly, the rhythmic expansion and contraction of the muscles increases the flow of blood to the limb, thus giving locally to the muscles and tissues added nutrition and consequent tissue change.

Passing now from theory to practice I can assure you that in a relatively short space of time the good results following the careful use of these machines

will become apparent in the children themselves. They are admonished to try and work the machine as soon as they appear to grasp its fundamental principle and have recovered from the first few frights anything new imparts. In this way they learn to use actively whatever muscular power is remaining—let us say alive—in the limb, increasing it; and thus bring the frequently only dormant fibres of apparently dead muscles into rhythmic play, soon becoming active. The effect is nearly magic. The flabby, thin, cold limb increases in size and solidity, and becomes pink and warm; contractures of the joints, if present, are gradually and painlessly overcome, in fact, can be prevented if they have not as yet occurred. The child's mind brightens, it loses its sickly stoicism consequent to long confinement, takes interest in its own progress, and will soon try to work its limbs actively without being urged. Furthermore, the general health of the child makes rapid strides forward, and there is an increase in its appetite and general body weight. No passive exercise manually done, no free exercise could so well accomplish this desired result; for in the first place the exercises would and could not be executed rhythmically and graded, and secondly, the child's brain cannot formulate any distinct movement independently and execute it. The fundamental principle upon which the pendulum machine is built is simple: Upon one end of a revolving axle a weight and pendulum are attached, at the other end by means of removable sandals or leg cups the limb or part to be exercised. The pendulum is now set in motion, either passively by the attendant or actively by the patient, and swinging to and fro gently and rhythmically exercises the part

FIG. 2.—Clockwork machine.

of the body attached at the other end. One advantage to note is that the pendulum can be attached at any plane to the axle so that one can stretch any group of muscles desired.'

At first the child spends about five minutes exercising each part, and, as the work becomes more active, this time is gradually increased to fifteen minutes, never up to the point of fatigue.

1, *b, Massage and Electricity*.—Massage I consider one of our main adjuncts to the successful treatment of infantile paralysis. The manipulations consequent to it are apparently so easily mastered that, unhappily, its professional standard in this country has been lowered by its promulgation in the hands of charlatans and fakirs. In fact, I have had to hear that it lowers the dignity of our professional standing to make use of it personally. I disagree with this, for it seems to me that what one

harmful and dangerous; correctly administered it is of marked benefit. Rubbing the limb, as so frequently done by parents, up and down more or less rapidly, is but misguided energy wasted.

Electricity can, in my opinion, hardly be placed in the same category with pendulum machine and massage treatment. The intermittent galvanic current is useful in that it momentarily excites the muscle fibres, thus causing frequent slight contractions and expansions of them, but the local and general toning nutritive effect before mentioned is lacking. It also cannot prevent contractures, nor overcome them when present. The faradic current, I think, only unduly excites and frightens the child, without much benefit; but I suppose on account of its wholesome, buzzing sound, pleases the parents.

1, *c, Hydrotherapy*.—The manner in which I advise it is the following: Into a basin, pail, or tub large enough to hold the affected limb, hot water of about 100° F. is poured. To this is added sea salt (one handful to about two gallons of water), and the limb is then allowed to soak in this for about five minutes. Upon withdrawal it is well dried with a coarse towel, and immediately encased in flannel bandages. This procedure is especially effective when the limb is blue and cold, as after long neglect, but I also advise its use in the lighter cases, as an adjunct to the other treatments just described, where the parents' intelligence promises its careful execution.

2, *Brace Treatment*.—The application of a brace to a child suffering from infantile paralysis is an absolute necessity, just as soon as it begins to use its limbs in trying to stand or walk. The brace is put on to keep the efforts of the still active muscles within normal bounds—aiding the weaker, restraining the stronger; to protect the weakened joints from injurious overstrain and stretching, and to hold the parts of the limb in their correct relationship to one another. The varieties of braces employed by their authors, and those indicated in each individual case, are too numerous to mention here, suffice it to say that in constructing the brace we must always bear in mind that it should be a help-mate, not a curse. It must therefore be as light as possible, extend no further than really necessary, and fit the limb correctly and snugly without causing undue constriction or discomfort.

But applying a brace is not the end of treatment, nor can an occasional visit for a new buckle or strap hardly be recommended. For if active remedial measures, such as just described, are not faithfully carried out during this time, regeneration may easily become degeneration, the limb getting miserably thin, hypersensitive, and the trophic changes in it marked.

3, *Operative Treatment*.—Under this heading many interesting treatises have been written and much progress made since Strömeyer's first epoch making tenotomy. The indications, in short, for operation are: a, To overcome those deformities resultant to the disease, not otherwise amenable to treatment. b, To reconstitute the limb and its parts to as nearly normal a relationship to one another as possible. c, To aid and increase the useful work of the still active muscles. d, If a limb is absolutely paralyzed and all joints are flabby (*Schlötter-*

Fig. 1. Pendulum machine.

wishes to teach correctly, one has to have a thorough knowledge of, and I apply it, where possible, myself in every case until I have sufficiently instructed the parent or nurse to know that it is thoroughly done. I usually advise massage for both legs at the beginning of treatment in all cases—even in those where only one limb apparently remained paralyzed; and in the more severe forms also include the muscles of the buttocks and back, the abdominal muscles, and the arms if affected. Each individual group of muscles receives its share of stroking, kneading, striking, and vibration, as demanded, starting upward from the toes and following its defined anatomical distribution; the act becoming more severe as the hypersensitiveness of the parts decreases. Lack of knowledge of or carelessness in the employment of massage I warn is

Eyes: Complete temporal hemianopia with an excellent example of Wernicke's hemiopic pupillary reaction, that is, the pupils reacted to light when this was thrown on the temporal half of the retina of each eye, but did not react when the light was directed to the nasal or blind half of either retina, showing an interference with the nerves in the chiasm, where the nasal portions of each nerve cross to the opposite side.

There was some blurring of the disc edges, but the eye grounds were otherwise normal. He had a convergent squint of about 20 degrees, but this had been present from early childhood.

There was absolutely no history of, nor any evidence pointing to, specific disease. The ears were normal. The left side of his nose was badly occluded by a marked deflection of the septum to that side with thickening. He had some postnasal dropping and evidence of disease in the posterior ethmoid cells and sphenoid sinus of the left side.

The case cleared up completely with rest in bed. While it looked like a condition due to hemorrhage the age and general state of the patient were against such a diagnosis, and the presence of the nasal faults made it likely that conditions in the sphenoid sinus were responsible for the trouble.

CASE IV.—W. J., a young man, was struck in the left eye with the prickly husk of a chestnut while looking upward into a tree on a nutting expedition. When he presented himself next day for treatment, the cornea and conjunctiva were literally peppered with the barbed spicules from the burr and a severe inflammation had set in.

Something more than twenty of the small thorns were removed at the first visit. A number had to be left, as they were broken off in the tissue and an excessive amount of digging would have been required to remove them. Unless one has had to deal with such a case it is difficult to appreciate how troublesome the removal of such slender spicules, deeply embedded in the cornea, may be. There happened to be attending the clinic at the same time a patient who had suffered a similar accident some years ago. The vigorous effort made in his case to clear out all the spicules was followed by reaction so severe that the eye became of little use for visual purposes.

Careful watching of the injured eye, with the use of atropine, warm bathing, and suitable collyria, made it possible to remove the embedded spicules one by one as they betrayed their presence. The edema and softening of the cells immediately about them rendered this comparatively easy. In this way all were finally disposed of with excellent results.

1076 BOSTON ROAD.

## BOTHRIOCEPHALUS LATUS.

(Abnormal Segments.)

By FRANCIS HUBER, M. D.,  
New York.

Though not indigenous in the United States, the occurrence of *Bothriocephalus latus* is not uncommon in our immigrant population. The geographical distribution of this variety is peculiar; it appears to have spread from certain points into the neighboring countries. In some places in Europe where it was formerly rare it is now becoming common. Common in Paris in the last century, it is now only seen in the imported cases.

The scolices, or plerocercoids, occur, especially in the pike, carp, salmon, etc. They are not killed by slight smoking, salting, or freezing. The mode of infection of fish is not known. The embryos of the *bothriocephalus* may be introduced through eating lettuce, as is stated to be the case in Switzerland. This is sometimes raised under irrigation from lake water, thus carrying eggs or meases to the plant, and thus explaining its occurrence in persons not fish eaters.

Stiles in Osler's *Modern Medicine* writes: "About thirty cases of infection with this parasite

have been recognized for the United States, chiefly among foreigners. Very probably it will become more commonly known in the United States, for now that special attention has been recently directed to it in several American medical journals, it will be more frequently recognized, and, further, it is highly probable that immigrants will infect the fish of some of our lake regions."

Nickerson (*Journal of the American Medical Association*, March 10, 1906), in speaking of the broad tapeworm in Minnesota, reports a case of infection acquired in the State. The latter occurred in a child of Finnish parentage, who was born in Minnesota, and had never been out of the State. This demonstrates the fact that the species has ob-

Anomalous variations of section of *Bothriocephalus latus*.

tained a foothold, at least locally, in this country. The author states that he has found the larvæ in American fish, caught in the Great Lakes. He attributes or explains the general freedom from infection enjoyed by Americans to the fact that our method of preparing fish for food tends to destroy the larvæ.

Some years ago, while still engaged in active practice, it was my fortune to run across seven instances in about as many years. These cases all occurred in people who had emigrated to this country from the Polish countries. The interesting specimen, the photographs of which are herewith presented, was passed by a woman about twenty-eight years old, who had been in this country some seven years. She was a neurasthenic creature, pre-

senting a high grade of anæmia. After the usual treatment with male fern, etc., a large quantity of the parasite, filling a large teacup about two-thirds, was expelled. Unfortunately no measurements were made. In examining the specimen, certain peculiarities were noted, which are brought out distinctly in the photographs. The best parts were preserved; the rest of the specimen, kept in another jar, was inadvertently thrown away. A careful examination of the separate portion shows the different stages of the anomalous variations of the different segments and sections.

As cases of bothriocephalus are infrequent in America, occurring only in immigrants, the topic is referred to in a superficial manner in most of the American textbooks. The abnormal appearance of the individual segment or series is not even referred to.

The subject of *Bothriocephalus latus*, particularly its relation to primary and secondary anæmia, has been thoroughly discussed by Dr. Robert N. Willson (*American Journal of the Medical Sciences*, August, 1902).

In describing the characteristics of the various parts he says: "Each segment contains at its centre a dark, bluish gray spot, which, on examination, appears in the form of an irregular rosette, marking the recurrence of the segments. This rosette never fails of appearance, though the segments, as already stated, may run together, be partially divided, or shown no demarcation whatsoever. The frequent occurrence of imperfect and abortive types of twin segments may be considered an almost distinctive feature of the bothriocephalus family, although seldom or never mentioned in the textbook descriptions. The segments may also be split, either at the free edge or in the parenchymatous lateral portion of the body. I do not look upon these irregularities as always due to traumatism or pressure, but consider them, especially the imperfect and twin segment formations, as typical malformations."

A more plausible explanation is given by Jacobi, and is as follows: "Sometimes they appear fenestrated in consequence of the bursting of the sexual apertures. Thus a genuine fissure may occur, which yields the impression of a double development" (Jacobi, *Intestinal Diseases*, etc., page 251).

209 EAST SEVENTEENTH STREET.

#### CHOLERA INFANTUM

*An Avoidable Plague which Annually Kills Forty Thousand Babies in the United States.*

By LEONARD K. HIRSHBERG, A. B., M. D.,  
Baltimore.

Assistant, Johns Hopkins Hospital.

Cholera infantum is a name loosely applied to a whole group of infantile maladies, which differ greatly in important particulars, though they have many characteristics in common. All are disorders of the digestive tract; all are caused by unclean or improper food, rarely by direct contagion; all are most prevalent in summer. A familiar synonym for cholera infantum, in fact, is "summer complaint." But this name is far from accurate, for cholera infantum, while most common and most

dangerous in the hot months, is by no means confined to the summer.

When cholera infantum appears in its true form—that is to say, as an infectious dysentery—it is an exceedingly fatal disease. Several authorities say that the death rate is more than 60 per cent., which means that two thirds of the children attacked by it die. In all large cities it is epidemic throughout the year, and in New York, where the dwellings of the poor are peculiarly crowded and insanitary, it causes approximately 12,000 deaths each summer. During the census year 1904, when the last mortality statistics were gathered by the federal government, there were 37,000 deaths from cholera infantum in the comparatively few cities and towns that made returns. In the whole country, the mortality was undoubtedly well above 50,000.

The most virulent and dangerous form of the malady is caused by a minute organism now believed to be identical with the germ which causes the terrible adult dysentery of the tropics. The germ was discovered by a Japanese scientist, Shiga, in 1898, and bacteriologists have, therefore, called it the *Bacillus dysenteriae* of Shiga. Two years later, the eminent American biologist, Dr. Simon Flexner, discovered an organism of similar appearance in the tissues of a patient named Harris, at Manila, and this was given the name of *Bacillus dysenteriae* of Flexner, or Flexner-Harris. It was soon noted that the two bacilli were practically identical, and since then it has been found that, besides causing tropical dysentery, they also cause cholera infantum.

Many able men are now studying cholera infantum and its organism, particularly at the Rockefeller Institute in New York, at the Johns Hopkins Hospital, and at some of the German universities. As yet no certain cure for the disease has been discovered, but there is good reason to believe that, within a few years, a protective vaccine will be perfected. When that is accomplished, it will be possible to vaccinate children against cholera infantum just as they are now vaccinated against smallpox. It is evident that this will mean a great reduction in infant mortality—a most important matter for the human race as a whole.

The cholera infantum bacillus, like that of typhoid fever, practically always enters the body through the stomach, and by the medium of bad milk or contaminated food. It lives and breeds in the intestinal tract, and manufactures powerful toxins or poisons which cause most of the familiar symptoms of the disease—the vomiting, the acute diarrhea, the fever, the abdominal pains, and the rapid wasting of strength. The onslaught is so severe that the little patient sometimes dies within a week, and even when recovery follows an attack, convalescence is always slow and precarious, and the danger of sudden relapse and collapse is always great.

In its war upon this terrible malady modern medicine must depend, as yet, on weapons that are necessarily crude. An effort is made to remove the bacilli and their toxins from the intestines by irrigation, and stimulants are employed to combat the distressing exhaustion. In addition, the fever and other symptoms are combated in the manner that seems least harmful, and an effort is made to administer nourishment. Further than that some aid from drugs and baths may be obtained, and it is there—

fore not remarkable that two thirds of the children who develop true cholera infantum die of it.

In many cases indeed, though the physician is practically impotent, hope must never yield to despair, and every effort must be made to keep the child comfortable and to prevent the spread of the disease to other children in the household. For cholera infantum, as has been mentioned, is decidedly infectious, and every case is apt to be followed by other cases. Therefore, when the disease appears in a house, it is well to employ the same safeguards against its spread as would be employed in a case of typhoid. All the bedclothes and other fabrics in use in the sick room should be well soaked in a mild solution of some effective germicide—carbolic acid or corrosive sublimate, for instance—before they are sent to the family laundry, and care should be exercised in disposing of the water used to wash the patient. Other appropriate precautions will suggest themselves when it is remembered that the intestines of the patient and their secretions are fairly alive with virulent bacilli.

To prevent cholera infantum it is necessary, first, to reduce the risk of direct infection to the minimum, and, secondly, to keep the child in good general health, so that in case of chance infection it may be in a good condition to make a successful fight against the disease. It must have fresh air, proper clothing, and nourishing food. Both results may be attained by a proper supervision of its food supply. It must be fed intelligently, and it must get pure food, which means, not food which merely looks good and smells good, but food which is nourishing, easily digested, and absolutely free of all deleterious organism. The child must also be kept clean by frequent bathing.

Volumes may be inscribed with rules for hygienic and dietetic prophylaxis of infantile dysentery. The opportunities for the greatest of modern philanthropies hovers about this important matter.

Calomel and castor oil are the cathartics of choice which act on the small bowel, but they must often give place to stomach lavage and colon irrigation; the latter are quicker and safer methods late in the attack.

The aid and importance of most drugs, except opium, resorcin, and bismuth, and their allied and analogous chemicals, is much overestimated.

Lime water, sodium bicarbonate, magnesium, and the alkalies help in the vomiting of the acute stage. In later stages, a few drops of a dilute acid help. Astringents usually do harm. In cases of severe prostration mustard baths, hot packs, and saline infusions may be employed. One half ounce of old brandy in twenty-four hours will be well borne by an infant ten months old.

It is a lamentable fact, but one which no observant physician will deny, that mother love causes almost as many deaths among babies as neglect. About the business of "raising" babies—certainly the most important profession in all the world—there has been grouped a mass of traditions and superstitions whose practical effect is a needless and enormous increase in the infantile death rate. Ancient grandmothers, entrenched behind the fact that they have "raised a dozen children and lost none," appear with all sorts of ridiculous lore regarding

baby food and baby dressing, and it takes a great deal of firmness and ingenuity on the part of the physician to combat them and put them to rout. Too often he is put to rout himself, and has to content himself with rectifying the damage they have worked.

For instance, I was called in to ease the last moments of a poor little child whose life was ending at four months. The baby had cholera infantum, and was dying of it, and nothing could be done but make its death painless. And why was it dying? Simply because its grandmother—a presumably sane and intelligent woman—had insisted that it be given a "taste" of every dish eaten by its mother, on the theory that it would thus progress most easily and safely from a diet of milk to one of adult food. The poor child's digestive apparatus was broken down entirely by this incredible barbarity, and stray germs of cholera infantum found it an easy victim. Yet if the grandmother had been told that she was directly and unmistakably responsible for the baby's death, she would have protested violently, and, in all probability, would have instituted an action for criminal slander.

Superstitions such as this are by no means few, nor are they confined to the ignorant. Many a mother of undoubted intelligence provides her baby with one of the rubber or ivory nipples called "comforters" or "pacifiers." The theory of this is that the "pacifier" will keep the baby quiet, divert it from sucking its thumbs, and, by giving it something to employ its gums on, help it to cut its teeth. This is the theory. In sober reality, the pacifier merely serves to make the baby querulous and peevish, to teach it bad habits, and to fill its mouth and body with the germs of half a dozen diseases—from cholera infantum to diphtheria and from chicken-pox to meningitis.

The baby is dumped into its perambulator, with a pacifier in its chubby fist, and a nurse girl is told off to take care of it. In a moment it drops the pacifier, and the nurse rescues the deadly implement from the sidewalk. If she is careful she wipes it with her apron or handkerchief; if not she jams it into the baby's mouth without wiping. In either case there are ten chances to one that it is fairly alive with germs. Wiping a thing with an apron or dusting it with a brush or washing it with soap does not rid it of the organisms of disease. The only way to do that effectively is to boil it steadily for at least half an hour. And whoever heard of a nurse girl who boiled her charge's pacifier for half an hour before putting it to its disgusting and nefarious uses?

In pacifiers, rubber rings, and things of that sort cholera infantum lies. One authority estimates that from 5 to 10 per cent. of all deaths among infants less than two years old are due to infections by such or similar means. The average child, luckily enough, has an almost uncanny power for resisting virulent organisms. Its hold on life, despite its physical weakness, is strong, and it has a wonderful capacity for recovery. If that were not true, the average child, in the face of its almost constant exposure, would die.

There is no truth whatever in the common superstition that children must have something to exercise their gums on. The baby's liking for such things is

a habit, pure and simple, and a bad habit at that. It is just as easy to teach it to do without its rubber ring—just as easy and a great deal more humane and sensible.

Ten days after they are born babies begin to acquire habits. These may be bad habits or good ones, according as the mothers act sensibly or the reverse. If the mother of an infant—or its grandmother or aunt or nurse—rocks, bounces, or nurses it every time it cries, it almost immediately notices the connection between the two things, and so a bad habit is formed. If, on the contrary, a deliberate effort is made to teach it good habits, it will acquire them just as quickly and cling to them just as tenaciously.

During its first few months a healthy infant should be fed regularly every two hours from daylight until eleven p. m. Then it should be put to bed and kept there, without food, until five o'clock the next morning. In the case of a baby who has been fed every time it cries, the inauguration of this régime will almost certainly bring forth heart breaking protests. The first night, for instance, it will yell most piteously, and so, too, the second and third nights. But after that it will go to sleep when it is put to bed, and sleep without interruption until daylight. And when it does that, it will have acquired a habit that is healthful and normal and one that will conduce to its good health to the end of its life.

The baby which sleeps by fits and starts and must be walked up and down the floor is a baby with an unwise mother. Any one who does not believe this should pay a visit some night to an up to date maternity hospital, wherein skilled nurses take the place of meddlesome grandmothers. There may be fifty babies in the place, but except among those who are violently ill not a sound will be heard between midnight and dawn.

The connection between bad habits and illness is obvious. The baby which frets and fumes is constantly wasting its energy and losing its proper rest. Its power of resistance is thus lowered, and when the germs of disease assail it, it falls an easy victim. The serene and good tempered child, which has been taught to eat and sleep with regularity, is almost invariably healthy. And the child who has a mother sensible enough to teach it good habits, almost always has a mother sensible enough, too, to protect it from pacifiers and to feed it upon appropriate and clean food.

The best of all food for the baby is that provided by Nature. When unavoidable conditions put this out of its reach, its mainstay should be pure or modified cows' milk. In all large cities there are companies which sell this milk, so prepared that it contains, in exact proportions, the ingredients recommended by the family physician. To feed the milk sold by the average neighborhood milk dealer to the baby, particularly if that milk be unboiled, is little short of assassination. There was no need for President Roosevelt to point out this fact. The mortality tables had revealed it long before it was brought to his attention.

Often it is difficult to inquire closely into the source of the family milk supply, but in all cases it pays to take the trouble. The milk given to infants

should be absolutely free of germs, and this freedom can only be obtained by proper pasteurizing. Therefore, the family physician should be consulted and his advice followed. He should be consulted, too, when it is proposed to feed the baby on any one of the many artificial foods on the market. Many of these are most excellent, but it is necessary that the peculiar needs and idiosyncrasies of each baby be properly studied and understood before they are administered.

Next to pure food, the most important thing for infants is fresh air. The atmosphere of the average house in the average city is heavy with the waste products of respiration, dried germs of all sorts, and various other things. A child breathing it day after day is almost certain to lose in vigor. Fortunately, however, parks are plentiful, and their air is always comparatively clean. Therefore, the baby should spend much time in its perambulator and under the trees, particularly in summer.

A great many children are made ill, in winter as well as in summer, by too much coddling. Infants, it should be remembered, are far more sensitive to heat than adults, and their skin, when the air does not reach it, is very liable to painful and persistent eruptions. A baby born during the warm weather should be put into short clothes at once—despite the ancient and powerful belief that the virtue and intelligence of a mother is to be measured by the length of her baby's clothes. After the second month, in the hot season, the child should be practically naked, day and night.

1937 MADISON AVENUE.

#### A SHORT RESUME OF THE COMMON CONJUNCTIVAL AND CORNEAL DISEASES.\*

By A. J. HERZIG, M. D.,  
New York.

Before proceeding with the description of the various eye diseases thus enumerated, I will give a method of examining the conjunctiva and cornea. Exposure of the lower conjunctival sack is performed by pulling the lower lid downward with the thumb and telling your patient to look up. Exposure of the upper lid is as follows: Grasp the central lashes between the thumb and index finger, draw the lid forward, downward, and outward, while with the other hand press with the finger or toothpick at the upper margin of the tarsus, at the same time directing your patient to look downward. Pay special attention to the transition fold as to ulceration and granulations. Inspection of the cornea is as follows: Use a strong convex lens and concentrate the light from the window or any other artificial illumination on to the cornea. In examining children it is better to have them held from attendant's or parent's lap with the child's head between your knees.

#### Foreign Bodies in the Conjunctiva.

A foreign body in the conjunctiva is usually found under the upper lid and easily removed by forceps. A loose object may pass into the upper conjunctiva, and this often causes the characteristic

of the physician, who tells the patient there is nothing in the eye. When seen, it is easily removed by being pulled out with a small forceps.

#### *Injuries.*

Injuries to the conjunctiva are common, such as contusions, burns, wounds, insect bites. Contusion (black eye) is easily diagnosed. Treatment consists of ice applications and later massage. Should an abscess result, it should be incised and drained. Wounds should be dealt with surgically. Insect bites cause a great deal of swelling sometimes, but this is easily reduced by iced compresses. Burns are best treated by some bland ointment such as a one per cent. ointment of yellow oxide of mercury. In extensive burns, skin grafts are required after a proper treatment.

#### *Catarrhal Conjunctivitis.*

This is subdivided into acute, chronic, and follicular. Acute catarrhal conjunctivitis is usually accompanied by a mucoid or mucopurulent discharge; conjunctivæ red and swollen. There is a congestion of the bulbar conjunctiva. In severe cases œdema of the bulbar conjunctiva (chemosis) is present. Secretion also appears as scales adhering to the margins of the lids. The patient complains of an itching or burning sensation of the lids, which feel hot and heavy, as though there was a foreign body in the eye. There is more or less photophobia present, according to the degree of inflammation. This condition may affect one or both eyes. Treatment consists in applying hot or cold compresses. I usually find heat the best. The conjunctiva should be touched up daily until the acute symptoms have subsided with a one per cent. solution of silver nitrate. The patient is to use a mild astringent, such as a one half per cent. solution of zinc sulphate in camphor water, at his home every three hours and later three times a day.

#### *Chronic Catarrhal Conjunctivitis.*

This has similar symptoms to those of the acute form, but a great deal milder in severity. The secretion is slightly altered and more profuse in quantity. It is more mucoid in character. Treatment consists in the regular applications of a one per cent. solution of silver nitrate to the conjunctiva every two or three days, as is necessary. I usually give the patient a mild astringent to use at home. These remedies may have to be changed from time to time.

#### *Follicular Conjunctivitis.*

Follicular conjunctivitis is divided into two forms, namely, fine granules and those that have large lymphoid granules. Examination reveals in the former fine sandpaperlike granules, which appear on the upper conjunctiva and transition fold. These may be associated with large lymphoid granules so commonly met with and so often mistaken for trachoma. (Some authors state that this condition is a primary stage of trachoma). These lymphoid granules are found more commonly on the lower than on the upper lid, but are commonly present on both. Symptoms are those of catarrhal conjunctivitis, with a feeling of a foreign body in the eye and profuse discharge, although in some cases the discharge is absent. In the sandpaper like granular form, with

little secretion, I prefer to use a one per cent. yellow oxide of mercury ointment to be applied into the lower conjunctival sack three times a day and then gently massaged. It is a practice with me to treat these granular conditions with blue stone, as the large lymphoid variety succumbs to this treatment in very short order. These large lymphoid granules are easily expressed by a roller forceps, and cases have been credited to a cure of trachoma instead of granular conjunctivitis.

#### *Acute Epidemic Conjunctivitis, or Pink Eye.*

This disease occurs most frequently in the spring or fall season. It is generally bilateral and has all the symptoms of an acute conjunctivitis, with all the symptoms exaggerated, and a very profuse mucopurulent discharge. Treatment consists in giving the patient an astringent wash to use at home and to keep the eye free from irritation, such as dust and tobacco smoke. I treat these patients daily at first, and later as the condition gets better, less and less. I use a one per cent. silver solution in all these cases. Bathing the eyes with very hot water night and morning is of great benefit to these patients. It is well to keep these patients away from other children, as the disease is highly contagious, and also to caution them about being particular in avoiding to use other towels, napkins, etc., than their own.

#### *Trachoma.*

Trachoma is an infectious disease attacking the conjunctiva of the transition fold of the upper lid primarily, and firstly manifests itself by minute ulcerations along the transition fold with fine sandpaper like granules. These are very easily demonstrated by everting the upper lid and placing the margin of the lower lid under the transition fold. These ulcers are minute, and appear as a series of white spots in contradistinction to the red tissue intervening. The other of the granular forms of conjunctivitis may or may not accompany the trachoma. In the examination of trachoma I have been able to see and demonstrate this condition in every case of beginning or incipient trachoma. This was first brought to notice by Dr. R. O. Born in 1901, under whom I have had the opportunity of seeing and studying many cases. In the later stages these ulcers disappear, to be replaced by cicatricial tissue. In a hundred scrapings taken from these patients I have not been able to demonstrate any special organism, the staphylococcus being present in fourteen cases and the gonococcus in one case. Other examinations were negative. Treatment is nonoperative, as trachoma, being a nongranular disease, there is nothing to squeeze out. Truly, the large lymphoid granules are readily squeezed out and easily cured, but not the trachoma. The proof of this is that in a great number of cases where the patients have been operated upon for trachoma, these same patients come back after operation with the trachoma remaining. Trachoma is curable in the primary and secondary stages (hypertrophic) by the careful application of blue stone. The tertiary (or scar) stage is incurable as regards to curing the scars, although these patients are relieved from time to time by the use and application of blue stone and silver. The diagnosis of trachoma can

never be made without examining the transition fold for these ulcerations—that is, the incipient stage. Also, cases of trachoma should not be subjected to a squeezing operation, as the resulting scars of this method are worse than those of a trachoma. I have never seen a case of genuine trachoma successfully operated on and cured, while I have seen hundreds of cases cured by the application of the blue stone. Why operate when you can cure these patients by the applications of blue stone? In cases of so called trachoma I have, after eight to fifteen applications, found a good, clean, smooth conjunctiva resulting. In cases where there is an underlying trachoma, the trachoma will remain after the granules have disappeared. A word of advice as to the application of blue stone. *Never* apply blue stone to the upper portion of the everted lid, only under it and along the edge of the transition fold. The injudicious use of blue stone upon the upper tarsal folds causes scar tissue after long use. The home treatment of these cases is the same as that of conjunctivitis.

#### *Blennorrhæa (Adultorum).*

After a period of incubation the lids swell and become edematous, hot, and red. The conjunctiva is intensely swollen, very red, and often so intense as to prevent opening the lids to inspect the cornea. The secretion is often reddened like blood juice mixed with flakes of pus. The preauricular glands are often swollen and sensitive to the touch. The positive diagnosis is made by examining the secretion and the finding of Neisser's bacillus. It ordinarily takes from two to three days for the disease to reach its height, then the secretion becomes purulent. A membrane may often be seen superficially; small infiltrations may make their appearance now. This is the stage when the cornea is usually involved unless precautions are taken. The treatment consists in protecting the other eye by means of a shield of isinglass, and frequent cleansing of the affected eye with a 1 in 3,000 bichloride solution and the daily application of a two per cent. silver nitrate solution. I have these patients apply iced compresses continually day and night. This is best done by placing a small piece of ice in a basin, surrounding it with sterile gauze, and having quite a number of small cut squares of gauze about an inch square laid on this gauze. The gauze is changed every minute or so, so that the patient has the constant effect of the cold. After using these compresses for a time I advise them to be burnt. When the swelling has gone down considerably I substitute blue stone for the nitrate of silver solution.

#### *Blennorrhæa Neonatorum*

Blennorrhæa neonatorum occurs in newly born infants as a result of an infection of the eyes during the passage of the head through an infected vagina. The symptoms run the same as those in adults, only much less severe. The danger of suppurative of the cornea is not as great as in adults. The treatment is the same. In cases where the suppurative is profuse I apply the two per cent. silver nitrate solution twice daily. Prophylactic treatment should be more strongly advocated than it is. A two per cent. solution of silver nitrate should be dropped into the baby's eyes immediately after birth.

#### *Conjunctivitis Diphtheritica.*

This is an infectious disease of the eyelids caused by the Klebs-Loeffler bacillus, and resembles blennorrhæa in its symptoms and course. The infiltration in these cases is more marked than the blennorrhæal form, and the induration is greater. A membrane is seen which bleeds easily upon removal. This appearance with a positive culture concludes our diagnosis. Treatment consists in the injection of antitoxine, in keeping the eye clean with a mild antiseptic, and, lastly, in the application of cold.

#### *Croupous Membranes.*

They may also be seen in severe conjunctival catarrh or as a result of burns. Bacteriological examination will settle all doubt as to the cause of the membrane, and the treatment is symptomatic.

#### *Phlyctenular Conjunctivitis and Keratitis.*

These affections occur so frequently together that I will enumerate them under one heading. Some writers group these forms under those of conjunctivitis eczematosa. No real eczema occurs in these cases, for these so called eczematous symptoms disappear under proper treatment of the eye. These conditions occur most frequently in children who belong to that class designated lymphoid diathesis. They have the enlarged glands adenoids, tonsillar hypertrophies, and sometimes the large lymphoid granules of the conjunctiva. These conditions are dignosticated by small elevations being seen upon the conjunctiva or cornea followed by a streak of bloodvessels, which usually range themselves in the shape of a pyramid having the phlyctenule at the apex of the pyramid. Circumcorneal injection in these cases is marked, and blepharitis is often present. I treat these cases firstly by giving the patient calomel internally to use at home and also yellow oxide of mercury to be put into the lower conjunctival sack two or three times daily. Apply a one per cent. solution of silver to the phlyctenules direct; at first daily, and later as the condition improves two or three times weekly, etc. These phlyctenules usually disappear in from ten to twenty-one days under this treatment. If there is any coexisting condition of the lids treat it with castile soap and water.

#### *Ulcers.*

Ulcers of the conjunctiva sometimes occur after a severe conjunctivitis, but most commonly follow a burn by heat or caustics. These ulcers also occur during the various exanthemata, but the commoner forms are those of a chalazion breaking through the conjunctival wall. Acute ulcers of the conjunctiva are rare, and when seen are accompanied by a swelling of the lids, considerable pain, enlargement of the preauricular glands, and purulent secretion. Ulcers occurring as a result of degeneration of an epithelioma of the conjunctiva and specific ulcers from degeneration of a gum-sarcoma are our greatest rarities. The treatment of ulcers is the treatment of the cause.

#### *Injuries.*

Injuries of the conjunctiva are such as lacerations and burns. Wounds should receive proper surgical treatment; such burns are produced by hot water, steam, caustics, hot vapor, ashes, molten metal, electric flashes, exploding powder, and flames striking

the eye. Burns by caustics, especially lime in the form of mortar, cause eschars. These spots stand out as gray or white patches in a sea of swollen conjunctiva. These ulcers sometimes suppurate, and are always followed by a scar. Symblepharon often follows an extreme burn. Treatment consists in the use of a one per cent. solution of atropine sulphate every three or four hours, cold compresses, and a bland wash for the eye, such as a dilute solution of a concentrated solution of sugar, as that forms an insoluble compound with the lime. After a separation of the eschars, our aim is to draw the lids away from the eyeball to prevent adhesions. To enumerate these various methods would occupy too much time, and I only wish to suggest the use of the yellow ointment of mercury thoroughly applied into the upper conjunctival sack, as this has proved successful in my hands. In cases of burns by caustic alkalis do not use water, but use milk.

#### *A Pterygium.*

This is a triangular fold of mucous membrane which extends from the ocular conjunctiva to the cornea, either to the inner or outer side of the latter. A pterygium of recent origin is succulent, and is plentifully supplied with bloodvessels. We have two varieties of pterygium—a stationary and progressive variety. The progressive form keeps on growing until it reaches the centre of the cornea or crosses the centre. Its greatest danger lies in obstructing the vision. The stationary form remains stationary, but does not progress, as its name implies. The treatment of these conditions is entirely operative. We have numerous operations of this condition, but I will only describe the one which has proved most successful in my hands. I prefer the method of splitting the pterygium in the horizontal plane after having separated it from its corneal attachment and turning the lower flap downwards and backwards. I then fasten this flap into its position by several silk sutures. The same is done with the upper flap, only upwards.

#### *Symblepharon.*

Symblepharon occurs after wounds of the conjunctiva or cornea, by burns, etc. We have several degrees of symblepharon which I will not go into. Let it suffice to mention that the treatment consists of a plastic operation. Various varieties and positions of the symblepharon require different procedures, and to describe any of them in preference to the other would be great injustice, hence I leave this subject to your own individual experience.

#### *Subconjunctival Haemorrhage.*

Such a haemorrhage is easily diagnosed by a bright red patch of blood seen under the conjunctiva, usually under the bulbar. This condition develops after injuries (after squint operations) in severe inflammations of the eyeball, such as glaucoma or very commonly after a blow. Spontaneous effusions occur in old people, whose bloodvessels have brittle walls, or may be occasioned by any extreme exertion, such as sneezing, coughing, vomiting, or great straining. In children whooping cough is a great factor as a causative agent in producing subconjunctival haemorrhage. The treatment, provided that glaucoma be excluded as a causative factor, is *nil*. Application of iced compresses hastens absorp-

tion of the clotted blood and reduces the swelling. I have used adrenalin chloride in various strengths in these conditions without satisfactory results. I will next endeavor to point out and describe the various affections of the lid and lid margins. I will only briefly mention the local skin disorders one meets with in clinical and private practice. We see the various exanthemata, herpeszoster, eczema, erysipelas, etc. The treatment for these conditions must be sought for elsewhere. Plegmons of the lids are easily recognized, and should be treated by incision and drainage. Ulcers of the lids are caused by injuries such as burns, contusions, or occur spontaneously. We also have ulcers due to lupus and syphilis. The treatment for these conditions will be to treat the cause.

#### *Edema.*

Edema of the lids is a symptom and not a disease; it is of such great diagnostic importance that I mention it here and go into it in some detail. We see it in erysipelas, infection of an operative wound, such as iridectomy or cataract extraction, acute glaucoma, iridocyclitis, insect bites, ivy poisoning, severe blepharitis, infections from an abscess—e. g., hordeolum, gonorrhoeal ophthalmia, traumatism, panophthalmitis, tumors of the orbit, thrombosis of the cavernous sinus, angeioneurotic edema, tenonitis, and plegmon of the orbit. It also occurs with a severe ethmoiditis.

#### *Distinctive Diagnosis.*

Erysipelas.—The redness and swelling of the lid are uniform, circumscribed infiltration being absent. The skin of the lid when grasped between the fingers feels thicker and harder than the other varieties of edema. The swelling extends to both lids and also extends to neighboring parts. In post-operative infections the edema usually presents itself on the upper lid. The appearance of the operative wound will give us our diagnosis—that is, an amount of retained lachrymal secretion is present and a grayish discoloration is seen about the corneal wound. Edema accompanying acute glaucoma is diagnosed by the symptoms of glaucoma—e. g., foggy cornea, pain, increased tension during attack, dull iris, etc. Edema as a precursor of a severe iridocyclitis occurs along the upper lid usually. Diagnosis of iridocyclitis is made by its characteristic symptoms, which will define your cause of the edema. Insect bites causing edema are easily diagnosed by the small point which is seen where the insect has bitten. Ivy poisoning edema is shown by the characteristic skin lesion and the terrible pruritis. A severe blepharitis, whose diagnostic signs have already been pointed out, also causes edema. This is usually on the upper and lower lids, more so on the upper. Under this heading also comes hordeolum accompanied by edema of the upper lid. In palpating the swollen parts we find the edema close to the edge of the lid, and on looking at the lid margin see a yellow pinpoint between the cilia; we can be sure we are dealing with a hordeolum. Edema is also caused by an acute dacryocystitis, and is diagnosed by the character and situation of the swelling and the expression of secretion from the lachrymal duct by pressure. Another edema occurring during the treatment of an acute dacryocystitis is due to faulty

handling of the lacrymal spring, causing the medicated solution to enter the tissues surrounding the eye instead of the duct. Oedema caused by gonorrhoeal ophthalmia is severe and great in amount, involving the upper and lower lids. In some cases it is very difficult to inspect the cornea. When possible, a smear should be taken, the bacteriological finding of which will settle the diagnosis. Oedema caused by traumatism, the most common form being that of a black eye, is easily diagnosed by its history and appearance. Panophthalmitis having oedema as one of its signs is easily diagnosed by the previous course of the case, chemosis being present in these cases and the exudate purulent. Protrusion of the eyeball takes place early. Tumors of the orbit, causing oedema, speak for themselves as to their diagnosis. Thrombosis of the cavernous sinus is distinguished by the fact that the oedema also shows itself behind the ear of the affected side and that cerebral symptoms are present. Angioneurotic oedema is rare in this country, and occurs and disappears spontaneously; it occurs mostly in women. Oedema in other parts of the body are common in this condition. Absence of any inflammatory signs in the eyeball will also assist towards a correct diagnosis. Tenonitis and phlegmon of the orbit show similar symptoms, hence I mention both of them under the same heading. Oedema is present in both, as is chemosis, protrusion of the eyeball, and immobility of the eyeball. In tenonitis the protrusion of the eyeball is comparatively slight, while the oedema is marked; while in phlegmon of the orbit the oedema is less and the protrusion of the eyeball is very marked. Sometimes it is difficult to make a distinctive diagnosis till you see the pus breaking through. But, in all events, do not wait until this occurs.

Ethmoiditis causes oedema of the upper lid when it is pointing to an external opening. The diagnosis is made by an intranasal examination.

#### *Hyperæmia*

of the lid margin is seen in light complexioned people more readily than in those of darker countenances. It follows great weeping, late hours, bad dusty air, inveterate cigarette smoking, etc.

#### *Phthiriasis Palpebrarum*

This is due to the crab louse, which is very often found adhering to the hairs of the lids. The nits are adherent to the middle of the eyelashes in contradistinction to the scales of blepharitis, which are adherent to the roots of the eyelashes.

#### *Blepharitis.*

This is subdivided by some authors into an ulcerative and a nonulcerative form. I take it only as one form; the nonulcerative form being the primary stage of a blepharitis when the hairs have been attacked and loosened, the ulceration being the later stage of the disease. The diagnosis is made by excluding the crab louse, the scales being attached to the roots and not to the middle of the hairs, as previously mentioned. Removing the scales by means of castile soap and warm water will reveal brittle and stubby hairs, which fall out easily. In the latter stages small ulcerations are seen at the base of the hair follicles, which bleed easily. Treatment for hyperæmia of the lids is to remove the cause. The same holds true with the next subject, namely, the

crab louse. A three to five per cent. yellow oxide of mercury ointment applied to the lids will destroy the louse. Scrubbing the lashes with vinegar will greatly assist in removing the nits, which are most difficult to remove. In blepharitis I personally scrub the lids the first time with castile soap and water, in order to show the parents how to do this. I then apply a one per cent. solution of silver to the margin of the lids. Home treatment consists in giving these patients a one per cent. yellow oxide of mercury ointment to rub into the margins of the lids three times daily after thoroughly scrubbing the lids with castile soap and warm water and removing all the crusts. This latter operation is most important. The general system in these cases ought to be looked after and inquired into, as a great many of these little patients suffering from blepharitis have large glands, adenoids, etc. The administration of calomel in these cases is often of great advantage.

A *hordeolum* is an acute inflammatory condition of the glands of the lids, and may be external or internal in variety. *Hordeolum externum* is due to an infection of Zeiss's glands, while the internal variety, which is rarer than the former, is due to suppurative of the Meibomian glands. Diagnosis of the external hordeolum is made by palpating the lid and noting the proximity of the swollen tumor to the edge of the lids and its sensitiveness to the touch. Pain is present, and is often extreme. Pulling out a proximal eyelash will often reveal a drop of oozing pus. *Hordeolum externum* usually breaks through the skin; *hordeolum internum* hardly ever, as the tissue of the gland is denser and the root of exit of the pus is through the conjunctiva or through the only opening of the gland. Treatment of an external hordeolum is as follows: When I see a case not too far advanced I remove a hair, and this often drains the gland, in the meantime applying heat to the lids. When large or not responding to this treatment within forty-eight hours I advise incision. I incise the hordeolum along the edge of the lids preferably and thoroughly curette the cavity. In the internal variety I usually open and curette them at once. Yellow ointment may also be used, but I very seldom have seen its use abort a hordeolum as alleged by others.

*Chalazion* is a chronic affection of the Meibomian glands, and manifests itself by a hard swelling, which slowly increases in size. Inflammatory symptoms are very rare, but may be seen to occur should the chalazion become affected. The skin is perfectly movable over this variety of tumor, while it is not so over a hordeolum. This tumor can be felt attached to the underlying tissue. A chalazion does not lead to suppuration as a general rule, but keeps on enlarging from month to month until it reaches the size of a large pea.

Treatment.—Small tumors should not be touched. When larger and causing some interference with vision, or the patient's complaining of an unsightly appearance for which he consults you, they should be enucleated and not merely cauterized. This may be done externally through the skin, internally through the conjunctiva, or through the edge of the lid. Personally, I prefer the external incision, as it is the easiest and most satisfactory. The scar is so small as to be hardly noticeable; the incision be-

made horizontally. It is well to remove these tumors with their capsule, although often it is impossible to do so without cutting into them. The underlying necrotic tarsus should be thoroughly curetted. One or two silk sutures are put into the external wound and the eye bandaged.

#### *Trichiasis and Distichiasis.*

Trichiasis is a distortion of the cilia, which, instead of looking forward, look backward, so as to come in contact with the cornea. This condition occurs most frequently as a result of the cicatricial stage of trachoma. The contact of the eyelashes on the cornea finally causes ulcers and later blindness due to opacities. Distichiasis is where some cilia look forward and others backward, and in reality is a stage of trichiasis and need only be mentioned. Treatment is epilation. If this does not suffice I do plastic operation, which I will describe under treatment for entropion. Electrolysis has been used with fair success.

#### *Entropion.*

This denotes a rolling inward of the margin of the lids. The edge of the lid is inverted inwardly to various degrees, and, in fact, is a greater degree and later stages of trichiasis. The posterior margin of the lid is smoothed off, and the cilia brush up against the cornea. This is commonly caused by the later stages of trachoma. We have a spastic entropion, which is a spasm of the orbicularis palpebrarum and the cicatricial entropion, the latter of which I shall only take into consideration. The treatment is entirely surgical. The flap operation which I perform is as follows: The patient being properly prepared under cocaine anæsthesia (local) and an entropion clamp applied, I make an incision the whole length of the lid margin. I then excise the hair bearing portion of the tarsus with a scissor. My second step in the operation is to take a small narrow strip of skin from about the middle of the upper lid and place it in the excised portion, along the lid margin, where it is fastened with two end sutures of silk. The upper wound is closed by four to five sutures, the ends of which are drawn above the eyebrows and fastened there by strips of plaster, thus everting the lid margin and keeping it in this position until complete healing has taken place. The skin graft usually attaches itself within forty-eight to seventy-two hours. The patient is put to bed and kept there until the graft has attached itself. No other dressing except a clean piece of sterile gauze over the eye is necessary.

#### *Ectropion.*

This occurs as spastic, paralytic, senile, and cicatricial-forms. Spastic ectropion occurs mostly in children, and affects both upper and lower lids, and is easily seen by pulling the lids apart, when the lids readily evert themselves. Paralytic ectropion occurs as a result of paralysis of the orbicularis palpebralis and mostly affects the lower lid. The palpebral fissure cannot be perfectly shut. This condition is called lagophthalmus. Senile ectropion occurs in the aged, and involves only the lower lid. The giving of the elastic fibres in the tissues causes this condition. Cicatricial ectropion, which is due to burns or wounds, is the last of the varieties described here that is due to contraction of the lids by scar tissue. Treatment is only nonoperative in spastic ectropion.

It consists in applying a well fitting bandage over the weak tissues, so keeping the lids in place until the condition is cured. Electricity is used in the paralytic variety. If this fails operation is necessary. Senile ectropion is treated the same way as the spastic variety in its earlier and milder stage. In the extreme or later stage operation is indicated. Various plastic operations are in vogue, and to prefer one to the other would be foolishness. I use whichever operation suits my case.

#### *Injuries and Tumors*

of the lids must be treated surgically.

#### *Dacryocystitis.*

This may be acute and chronic. The diagnosis is made by the expression of mucopurulent or purulent secretion by pressure over the sack. Lachrymation is a constant symptom. In the acute form all the symptoms of an acute condition are present, namely, pain, tenderness, heat, and redness. Extreme swelling and œdema of the lid are frequently present. The chronic form gives a history of several years' standing, the acute symptoms being absent. The main symptoms being the purulent exudate which is easily expressed by pressure on the gland and intense lachrymation. Treatment of the acute condition is the same as that of any abscess, namely, drainage and relief of pain. This is often arrived at by the timely application of heat and passing a lacrimal probe through the duct, or at least attempting to pass it may open a way for drainage. This is often impossible. I give the patient a nasal spray of adrenalin chloride, 1 to 3,000. This helps a little in trying to open the lower end for drainage. When these measures fail, I make an external incision in the lacrimal sac and pass a large blunt probe through the incision to the nasal end of the duct, cleanse my wound, and drain it. I make daily applications of one to two per cent. solution of silver nitrate on a cotton swab to the interior of the abscess cavity. This will usually result in a cure. Should a fistula remain, proper measures must be taken for this condition. This will not be described here. Chronic dacryocystitis, in many instances, can be cured by probing the canaliculus and duct and having the patient constantly squeeze out the secretion at home. The office treatment consists of syringing the duct with a one per cent. solution of silver nitrate two to three times weekly, as is necessary. This has proved a cure in my hands in a great many cases. If after a thorough trial, say ten to twenty treatments with this method, I find no improvement, I advise enucleation of the sac. This may be done under local anæsthesia, using fifteen minims of a one half per cent. solution of sterilized cocaine and ten to fifteen minims of 1 to 1,000 adrenalin chloride injected around the field of operation. This anæsthesia usually lasts from thirty to forty minutes.

#### *Keratitis.*

Keratitis can be divided into suppurative and non-suppurative keratitis. Suppurative keratitis is subdivided as follows: Phlyctenular keratitis, ulcers of the cornea, keratitis due to lagophthalmus, neuro-paralytic keratitis, and xerotic keratitis. The non-suppurative forms are interstitial keratitis, pannus, vesicular keratitis, keratitis profunda, sclerosing keratitis, and ribbon shaped keratitis.

### *Phlyctenular Keratitis.*

This has been described under phlyctenular conjunctivitis. Its treatment is the same. Symptoms of ulcers of the cornea are the same, with different intensities, namely, pain, photophobia, blepharo-spasm, lachrymation, and interference with vision. Circumcorneal injection is intense. Neighboring parts are often involved, causing iritis, etc. Infiltration of the cornea is always present. Ulcer of the cornea shows itself as a grayish infiltration. This may extend, as an ulcer serpens, or remain stationary. It may advance around the corneal margin until crescent shaped as a catarrhal ulcer, or may appear as minute separate infiltrations along various portions of the corneal surface. These ulcers may be extensive, with great destruction of the superficial epithelium or even perforate. In the latter condition the irritation of the posterior endothelium of the cornea and the endothelium of the iris give off an exudate which settles in the anterior chamber as a hypopyon. In perforation we sometimes see Descemet's membrane bulging through the opening, forming a keratocele. Proptosis of the iris may take place at this stage.

### *Abscess of the Cornea.*

This occurs as a circumscribed yellow mass seen in the meshes of the cornea, and when seen must be incised and kept open. The crucial incision is the best. Symptoms of the above are severe, as those of an acute inflammation. Keratitis due to imperfect closure of the lids shows no different symptoms than those of any other form except the lagophthalmus is present.

### *Neuroparalytic Keratitis.*

This is observed after paralysis of the trigeminus. The keratitis may be trophic or due to exposure to foreign bodies and irritation on an insensitive cornea.

### *Xerotic Keratitis, or Keratomalacia.*

This is the result of malnutrition of the cornea. It is a rare disease and occurs mainly in greatly debilitated children. The diagnosis of ulcers of the cornea is aided by dropping two or three drops of a solution of fluorescein into the eye (fluorescein, 1.0; sodium carbonate, 1.5; distilled water, 30.0). The ulcers are stained green and are easily outlined in this way.

**Treatment of Ulcers of the Cornea.**—If the ulcer is small it will cleanse itself, which is shown by the appearance of sprouts of fine superficial bloodvessels running from the bulbar conjunctiva to the ulcer. In cases where the ulcer spreads, it is imperative to cauterize same. This may be done with the electrocautery or acids, tincture of iodine, or the actual cautery. The latter is done by heating a strabismus hook in an alcohol flame to red heat and cauterizing the ulcer and an area surrounding it, to prevent its spreading. This method is the safest, as the danger of burning deeply is done away with, for the iron cools readily. Should the ulcer perforate, a well fitting bandage is applied and complete rest ordered. Atropine sulphate, one per cent., should be instilled every four or five hours in all cases of ulcer of the cornea that have a tendency to extend or perforate. If the iris is seen protruding from the wound, it should be grasped with an iris forceps and excised. Samsa's method of splinting an ulcer with a Graefe knife is of value in severe forms of

indolent ulcers that perforate. In these cases the wound is probed daily and the anterior chamber is relieved of any secretion. In the other forms treat the cause. Ulcers after healing always leave scars in the shape of corneal opacities of varying intensities.

### *Interstitial Keratitis.*

This is seen first as a grayish infiltration, which is central and extending to the periphery. This infiltration is uniform in its distribution. Acute symptoms are present, such as pain, photophobia, lachrymation, and interference with vision. These latter symptoms gradually subside as the inflammation runs its course. This disease is usually bilateral, and usually occurs between the ages of fifteen and thirty, generally due to hereditary syphilis, although it may occur in acquired syphilis or tuberculosis or idiopathically; the three latter instances are extremely rare. Treatment is to treat the cause, namely, antisyphilitic treatment. Local treatment consists in the use of atropine and protection of the eye from light by means of smoked glasses or shields.

### *Pannus.*

This should have been described with trachoma, but as I wish to describe the various forms I will place it among the forms of keratitis. We have pannus due to trachoma, and pannus due to corneal ulcer. Pannus due to trachoma is a condition where the bloodvessels grown down and extend to the upper portion of the cornea and later cover it. These appearances, namely, broad expanses of vessels coming down from above with the appearance of ulcers along the transition fold (trachoma), completes your diagnosis. Pannus from corneal ulcer is demonstrated by the bloodvessels coming from any portion of the bulbar conjunctiva at the limbus and running to the ulcer. The bloodvessels range themselves fan shaped, having the ulcer at the apex. Both forms of pannus may be present in the same case. Treatment consists in treating the cause. If the vessels persist in spite of treatment of the cause, they may be scarified with a scalpel. Some cases resist all treatment. Pannus from corneal ulcer will usually clear up when the ulcer is cured.

### *Vesicular Keratitis.*

Large vesicles, such as buboes etc., occur under this head of vesicular keratitis, but as they are very rare, I will only name the common type, namely, herpes of the cornea. Herpes of the cornea is distinguished by a group of small, clear vesicles on the cornea. These are very painful and irritating, and cause considerable circumcorneal injection and lachrymation. This condition appears most frequently during febrile conditions—e. g., epidemic influenza, pneumonia, etc. Treatment consists in the local application of one per cent. of silver nitrate solution applied directly to these vesicles and an antiseptic wash for the patient to use at home.

### *Keratitis Perforans.*

This is a deep seated, gradual infiltration of the cornea, usually occurring in the centre of the cornea, in contradistinction to the interstitial keratitis, which is more extensive, and usually extends more toward the periphery. This condition usually disappears

spontaneously. Treatment consists of atropine and protecting the eyes from light and the underlying causes. Arlt gives rheumatism, intermittent fevers, and colds as common causes of the above named condition.

#### *Sclerosing Keratitis.*

This accompanies scleritis, and is a corneal manifestation of the latter. It is seen as a triangular opacity near the periphery of the cornea, having limbus as the basis of the triangle. Treatment is that of the scleritis.

#### *Ribbon Shaped Keratitis.*

This occurs as a gray film running as a band over the cornea. It occurs in old people, where the eyes have been injured by some intraocular affection. Treatment consists in removing this band and giving these patients an alkaline wash to use at home.

#### *Striped Keratitis.*

This occurs often after corneal section—e. g., cataract operations most frequently. Where the incision has been too small for the easy delivery of the opaque lens, this condition often occurs. It is of little moment, disappearing spontaneously in from eighteen to forty-eight hours, and requires no special treatment. This condition is seen as small parallel bands running up and down the posterior surface of the cornea.

#### *Foreign Bodies in the Cornea.*

They are easily seen by throwing a concentrated light on the cornea. They should be immediately removed, after dropping two or three drops of a four per cent. solution of cocaine into the eye. A spear shaped instrument which is made for this purpose is the best to use. If pigment or grayish ulceration accompany a foreign body in the cornea it should be scraped away, for, when left, it usually remains permanent. Very often ulcers form where the cornea has become infected, and it should be treated as such, after the foreign body has been removed. Warm compresses and a mild antiseptic, such as 1 in 5,000 bichloride solution, can be used after extraction of foreign body.

#### *Wounds of the Cornea.*

These should be treated by cleanliness, and if prolapse of the iris occurs it should be excised. Atropine should be used in both the above conditions, the eye bandaged and kept at complete rest. Burns by acids or alkalis have been fully described in burns of the conjunctiva, and usually affect both cornea and conjunctiva.

In conclusion I wish to state that I did not write this paper with an idea of giving a complete résumé of the subject, but rather a brief résumé, as the title of my paper states.

2040 SEVENTH AVENUE.

### CAUSE OF PREMATURE SEPARATION OF THE PLACENTA.

BY LIONEL ROSENBERG, M. D.,  
Brooklyn, N. Y.

I have come across some discussion in the medical journals about the cause of premature separation of the placenta, and among the causes mentioned I have found in the *New York Medical Journal* of March 14, 1908, that trauma is one of the causes.

This statement was made by Dr. Samuel Robbinovitz. I would like to call the doctor's attention that the cause given by him as trauma cannot act without a predisposing cause; and, furthermore, I would like to remark that the cause given by him is not original, as it is found among the exciting causes mentioned by Professor Jewett, given in the second edition of his well known work.

To state my opinion (that is, as far as my experience goes) of the causes of premature separation of the placenta, I would say that, in the cases I have had, I have found that metritis due to gonorrhoeal infection acted as a predisposing cause, and the least trauma caused by the midwife or physician in attendance acted as an exciting cause. To prove my statement I will cite the following case:

CASE.—Mrs. M. M., an Italian, age twenty-eight, multipara, came under my observation in September, 1907, and gave me a history of pain on urination, frequent urination, and a profuse vaginal discharge foul in odor. Upon examination I have found her to suffer from a gonorrhoeal infection probably due to her husband. Upon microscopic examination I found the gonococcus of Neisser in the vaginal discharge. I placed her under the usual treatment of gonorrhoea.

At the time she came to me she was about the end of the eighth month of pregnancy, and as she engaged me to deliver her infant, I inquired into her previous history, and found that she never had had any miscarriages or any complicated labors at all. She was healthy otherwise, and had no lacerations or injuries to any of the pelvic organs. Three weeks later she was confined, and as I could not come at the time of the delivery a midwife was called in to attend the case. The midwife, noticing some hæmorrhage, understood that the case was a complicated one and sent for me. I came and examined her, and found that the hæmorrhage was due to the premature separation of the placenta. After delivering the child, I injected a two per cent. solution of silver nitrate into the eyes of the child, as I knew that this was a gonorrhoeal case and was afraid for ophthalmia neonatorum.

I inquired of the midwife as to her procedure before I came, and she told me that she had applied friction over the abdomen in order to stimulate the pain, had also applied forcible pressure from above so as to help expulsion of the child.

Upon repeated examination I found that the patient had gonorrhoeal inflammation in its severest form, and so I came to the conclusion that premature separation of the placenta is due to the metritis set up by the gonorrhoeal infection, which acted as a predisposing cause, and that the manipulation of the midwife acted as an exciting cause.

I have had two more cases like this.

171 FLOYD STREET.

### IS IDIOPATHIC EPILEPSY WITH ASSOCIATED PARALYSIS DUE TO THE ACTION OF

A GERM?

BY BERNARD R. LE ROY, M. D.,  
Athens, Ohio,

Member of the Cleveland Academy of Medicine.

For some ten years the writer has suffered from the effects of paralysis of the lower bowels, following an operation for hæmorrhoids. Having been forced to give up practice because of the results of the paralysis and suffering want because of this restriction, the writer became interested in the study of paralysis, and after a careful preparation of several years' study began a laboratory study of all germs which would be possible to have any bearing upon such conditions; and this report is the first to be made public. After thousands of experiments I settled upon one germ, a spore bearing bacillus,

which in the normal state is about one to three micra in length by one half to two thirds in width, acid fast, motile, intensely so in certain media; is killed when grown on agar at 194° F., but when grown in media which have a small content of the silicates of calcium and magnesium it cannot be killed with prolonged boiling of the media; specimens living that have undergone fractional boiling of the media for over two hundred hours.

Growths taken from this specimen and grown as follows give peculiar results: In a faintly alkaline gelatine bouillon at 98.6° F. it resembles, when full grown, the *Bacillus typhosus*; transplanted to agar made less alkaline, and grown at 98.6° F., it resembles the *Bacillus tetani*; transfer to a faintly acid silicate lime, magnesium media, and grow to full size, then boil media and set aside for a few weeks, and the germ will resemble tubercle bacillus; now wash germs off and place in faintly acid gelatine media and grow for several weeks, and the germs will resemble *Bacillus diphtheria*.

Throughout all of these changes the germs will take the stain of the germ which it simulates, and can be distinguished with some difficulty; under certain conditions of growth the germ becomes ultramicroscopic in form, and after weeks of culture at 98.6° F. it reappears.

#### Clinical Use.

During the past summer it was my good fortune, through the courtesy of Dr. Hansen, the superintendent, to receive the privilege of studying for several months at the State Hospital for the Insane at this place, where, because of the more perfect conditions existing, the opsonins derived from these germs were first put into practical use.

In all cases no other remedial agent was or is being used except the opsonins. The opsonins were autogenous, and were made, as indeed all the work done, under strict laboratory methods and technique.

CASE I.—W. P., age twenty-eight, epileptic since childhood, was having many attacks daily, presented the typical appearance of such unfortunates. His mentality was clouded and he lived in that subconscious life which is so characteristic of these cases.

The germ was found in the discharge from the ear and in the upper nasal sinuses, was grown on agar until the germ was fully matured, then opsonins were made and a dose given; decided reaction resulted, and within twelve hours he commenced to feel better and more lively.

On the third day he was free from depressive effects and the attacks were much lighter in character and were not coming so often; by the fifth day his fits had vanished and was having auræ only. On the eleventh day his fits returned, and another dose was given him (one cubic centimetre); he then went nineteen days without an attack, auræ growing lighter, and improvement noticed generally; most interesting being the clearing away of the mental cloud and the peeping through of his normal mind.

Having no data to guide me, the index proving useless, I watched him until the spells or fits returned, when another dose of the opsonins was given, but during the next five days his fits came often but not very heavy; I then gave him a dose of the opsonins every four or five days thereafter, the reaction growing lighter with each dose, and at last did not even cause any remarks from the patient. After this he went nearly one month without spell or auræ, and was making fast improvement otherwise, especially in the clearing of his mentality.

CASE II.—J. V. F., aged forty-eight, inmate, suicidal homicidal, been confined within institutions for many years, was considered dangerous and an epileptic of severe form.

First dose was given in August and every four days thereafter, reaction severe, but gradually passing away as in Case I. This patient responded to the treatment slowly but steadily, and the fits died away, leaving auræ of a nervous type, which in turn faded away in much the same manner, but which had not entirely disappeared when I was compelled to stop all treatment on these two patients. Since then the fits have returned, but not so severe as before treatment.

CASE III, aged forty.—Wishing to try this treatment on a paralytic, I selected a case of hemiplegia (lucetic), and found the germ in the nasal cavity and in the groin.

A dose was given, and on the third day, after resting a while on a couch, he called to the attendant and asked if he were moving his fingers; he was doing so, opening and closing his fingers of the paralyzed hand, being hitherto unable to do so; five days after this he could move his arm and lift his hand into his lap; a second dose was given at the end of the second week, and within the next few days he was able to lift his hand up to his waist. Circumstances over which I had no control caused me to stop all work at this hospital; and I have not treated the patient since, and he has remained at a standstill since the last opsonic treatment was given, in spite of much medical treatment given him since.

CASE IV.—L. B., aged twenty, a private case. Epilepsy since early childhood, two to five fits daily; I found germs in the nasal cavity and in anal fold. I was at fault for some weeks in this case, and having discovered the fault I corrected it and at once obtained the usual good results, but along similar lines as described in Case II.

I hope to carry this case to a conclusion, it being still under treatment.

CASE V.—C. C., girl, aged nine, infantile paralysis, both lower limbs from waist down. I found germs in the nasal cavity and in anal fold. This child was a hopeless cripple, unable to move except to crawl in a peculiar fashion.

Treatments have been given once a week for several months, and the most decided improvement has resulted. With the aid of simple straight support to the knees, and crutches, she is able to travel about the house at will. The muscles are increasing in strength and in size, showing improved nutrition and action. I hope to carry this case out to a conclusion.

Thinking that there may be some other method of gauging the dose than by the index, which has proved useless, I made a careful analysis of the saliva in all my cases several times each day; the results proved to be quite interesting. I soon discovered that ammonia predominated in the saliva, with the chlorides second, an entire absence of the sulphocyanides. They may appear for a time, to again disappear before the fit and to be replaced by excess of ammonia.

Potassium as basic salt of the saliva is seldom found in cases of epilepsy, the base being sodium united with urea more often than with any other chemical.

Noticing the absence of the sulphocyanides from the saliva, I made use of the sodium sulphocyanide by the mouth and hypodermatically, and intend to write of my experiment later.

I also watched the effect upon epilepsy when the sulphocyanides were kept present in the saliva at all times.

I also found that when normal saliva was injected hypodermatically under proper precautions that it had a decided action upon the nerves, and may come into daily use as a therapeutic agent, it will stop mild cases of epileptic fits in young persons, but needs more study.

I am making a careful study of the germ, spoken of in this article, in all its forms and hope to be able to make a more full and complete report within the near future.

## Correspondence.

## LETTER FROM LONDON.

*A Sleeping Sickness Bureau.—The Royal Society of Medicine.—Tuberculin, etc., Administered by the Mouth.—Wright's Opsonic Method.—King Edward's Hospital Fund.—The General Medical Council.—The Death of Dr. Cullingworth.*

LONDON, June 2, 1908.

The British government has taken a very proper step to combat the alarming spread of sleeping sickness in Uganda and other districts. It will be remembered that a short time ago an international commission assembled in London to consider the question of a combined organization to deal with this problem. Unfortunately, owing to the disagreement between the delegates as to the locality of the central bureau, the commission dissolved without having accomplished anything definite. As the question is of pressing importance, the British government have now decided, without any further loss of time, to establish a central bureau in London with the object of collecting and distributing information with regard to sleeping sickness. The government of the Soudan will contribute one fourth of the cost of the maintenance of the bureau, and the Royal Society are allowing the use of Burlington House to provide the necessary accommodation. The bureau will be under the management of a committee consisting, among others, of Sir Patrick Manson, Sir Robert Boyce, Dr. Rose Bradford, and Colonel David Bruce. The main function of the bureau, which will be administered by a paid director, will be to collect from all sources information regarding sleeping sickness and to distribute this information as widely and as quickly as possible among those who are engaged in combating the disease. The publications of the bureau will consist of scientific works intended for those engaged in carrying on medical work in infected districts, and also publications of a less technical character for the use of government officials, missionaries, and others whose duties involve residence in those districts.

At a meeting of the Royal Society of Medicine held last Tuesday a discussion took place on the administration of vaccines and sera by the mouth. Dr. Latham made a communication on the treatment of phthisis by administering Koch's tuberculin "R." by the mouth, together with normal horse serum, 1/2,000 of a milligramme of tuberculin and 10 cubic centimetres of horse serum being given at intervals of a week. The temperature of the patient, which had previously been high, was reduced to normal and the general condition improved decidedly.

Dr. E. C. Hort said he had used normal horse serum with great benefit in various conditions. It was most valuable in hæmorrhagic diseases and in conditions associated with internal or external ulcerations. In bacterial lesions it seemed to stimulate repair of the tissues and inhibit the growth of the bacteria. The serum was administered by the mouth. He also referred to twenty cases, chiefly staphylococcal infections, which were treated by vaccines given by the mouth, and the results so far were encouraging. Dr. Rolleston also described a case of tuberculosis in which tuberculin was given by the

mouth, considerable improvement resulting. Dr. Hector MacKenzie said he was quite satisfied that staphylococcal vaccines could be administered by the mouth with good results, but he was still in doubt as to the value of the administration of tuberculin in that way. He also stated that in his opinion opsonic index estimations were not feasible as a routine control in actual medical practice.

The programme of the seventy-sixth annual meeting of the British Medical Association has now been issued. The meeting will take place in Sheffield from July 24th to July 31st, under the presidency of Dr. Henry Davy, physician to the Royal Devon and Exeter Hospital. The address in medicine will be delivered by Dr. Kingston Fowler, that in surgery by Dr. Pye-Smith, and Mr. Edmund Owen will deliver the popular lecture on Dust and Disease. The scientific business of the meeting will be conducted in seventeen sections. There will also be several social functions, including a reception of the members by the Lord Mayor. The annual dinner will be given on July 30th, and the programme includes also theatrical performances for the ladies and excursions into the country. The honorary local secretary is Mr. Sinclair White, F. R. C. S., Rammoor, Sheffield.

The *Practitioner* for May has a very important series of articles on the Opsonic Index and Vaccine Therapy. Sir A. E. Wright, in a long paper, very ably defends his theory, which has been subjected to considerable criticism lately. He maintains that clinical observations alone are uncertain guides to the administration of vaccines. The opsonic index, taken from time to time, gives the most reliable information as to the progress of immunization and as to the amount and frequency of inoculation of vaccines. He points out the service that opsonic index estimations have rendered to vaccine therapy, saying that all our present knowledge of the proper doses of vaccines, of the laws which govern the immunizing responses evoked by bacterial vaccines, and all our knowledge of the phenomena of autoinoculation have been derived from the opsonic index. The other papers in the *Practitioner* are all more or less in favor of Wright's theory. As there has been a growing tendency in England to dispense with opsonic index estimations during a course of therapeutic immunization by vaccines, owing to the difficulty in the technique, etc., this collection of articles in favor of Wright's method will perhaps result in further investigations on the opsonic index, so that a final verdict may be given as to its utility. For his work on opsonins, Sir A. E. Wright was presented with the Fothergillian gold medal by the Medical Society of London on May 18th.

King Edward's Hospital Fund has been enriched by a further munificent gift from Lord Mount Stephen. The same donor had previously given £400,000 to the endowment fund, yielding an income of about £23,000 a year, and the later gift will increase the annual income by over £7,000. The total income of the fund from investments is £60,000 per annum, so that over half the total income is derived from Lord Mount Stephen's gifts. It is suggested that an effort should be made to collect a further sum of £300,000 for investment purposes.

On Tuesday last the eighty-seventh session of the

General Medical Council was opened by the president, Dr. Donald MacAlister. In the business transacted was the adoption of a reciprocity agreement with the province of Quebec, whereby medical graduates of the McGill University, of Montreal, and of the Laval University, of Quebec, will be admitted to the Colonial List of the *Medical Register*. It was hoped that similar relations might soon be established with other provinces of the Dominion of Canada. It was also stated at the meeting that steps had been taken to secure a copyright of the *British Pharmacopœia*, to prevent unauthorized reprints. In November, 1908, the Medical Council will just have completed the first fifty years of its existence, and it is proposed to celebrate the jubilee by a friendly reunion to which all the survivors of the past members of the council should be invited.

Dr. Charles James Cullingworth, consulting obstetric physician to St. Thomas's Hospital, died last week at the age of sixty-seven. He was a general practitioner for some years after qualification. He then obtained an appointment at St. Mary's Hospital for Women, Manchester, and gradually gave up general practice and took up gynecology. He rapidly gained for himself a commanding position and was offered the post of obstetric physician at St. Thomas's Hospital, which he accepted. He took an active part in the promotion of those attempts at legislation which ended in the passing of the Midwives' Act of 1902. He was also editor in chief of the *Journal of Obstetrics and Gynecology* of the *British Empire*. He was the author of several articles and papers, the best known being his monograph on Diseases of the Fallopian Tubes and his article on Pelvic Inflammation, in Albutt and Playfair's *System of Gynecology*.

### Therapeutical Notes.

**The Desmond Reaction.**—An ingenious method of ascertaining the actual digestive power of the gastric secretion, suggested by Sahli, of Berne, was described in a recent issue of the *Bulletin des sciences pharmacologiques*, from which it is abstracted in *The Prescriber*, for June, 1908. The method is termed the "desmoid reaction" (Greek, *desmos*, a tendon or band), and consists in administering after the midday meal a pillule of methylene blue over which is stretched a piece of caoutchouc tied with catgut. Under the action of the gastric juice the catgut is dissolved, the caoutchouc contracts and sets free the methylene blue, which shortly afterwards appears in the urine. If the gastric juice be normal in composition the color appears in the urine in from five and one-half to seven and one-half hours after administration; a longer or shorter period indicates deficiency or excess of digestive power. The process is criticised by Altmann on the ground that the condition of the kidneys may affect the time of excretion, moreover, in the event of the gastric juice having no action on the catgut, the latter will dissolve in the intestine and similar results ensue. He therefore substitutes for the methylene blue a pearl of ether, coated with gelatin to prevent its floating, and tied up in caoutchouc as

already described. The sac is administered after an Ewald's test meal, and the exact time of solution is indicated by a characteristic eructation. In normal cases this occurs about an hour and a half after swallowing. The desmoid reaction is ingenious, but it is not exactly new. Günzberg, some fifteen years ago, suggested testing the stomach contents by administering a rubber capsule containing potassium iodide, and plugged with fibrin, and awaiting the appearance of iodine in the excretions.

**Laxative Preparations of Euonymus.**—In the *Journal of the American Medical Association* for May 2, 1908, a note is published on the therapy of euonymus or wahoo. The bark of the root is the most active part of the plant. It contains a bitter resin called euonymin, a crystalline glucoside termed atropurpurin, and citric, malic, and tartaric acids. The bitter principle euonymin is supposed to cause the laxative or purgative action of wahoo. Euonymus is a mild laxative, somewhat resembling podophyllum and rhubarb, only its action is weaker. It increases the secretion of the mucous membrane of the bowel, does not ordinarily cause griping, and as it acts but slowly, for laxative effects should be given from twelve to fifteen hours before its action is desired. It has been stated to have a slight tonic action on the circulation, slight expectorant and diuretic action, and to be a stomachic. None of these activities is of any importance. Some of its active principles are excreted by the kidneys, but probably it is mostly excreted by the intestines.

This drug is best used in combination, and may be combined with any other laxative to increase its action, as:

B Aloin, ..... gr. iii;  
Extract of euonymus, ..... gr. xv;  
Extract of belladonna leaves, ..... gr. iii.  
M. et fac pilulas 20.

Sig.: One pill after supper.

Or:

B Aloin, ..... gr. iss;  
Ipocastanea, ..... gr. iii;  
Extract of euonymus, ..... gr. xv;  
Resin of podophyllum, ..... gr. i.  
M. et fac pilulas 20.

Sig.: One pill after supper.

Or:

R Euonymus, ..... gr. iii;  
Extract of cascara sagrada, ..... gr. xlv;  
Extract of belladonna leaves, ..... gr. iiss;  
Extract of nux vomica,  
Oleoresin of capsicum, ..... aa gr. iii.

M. et fac pilulas 20.

Sig.: One pill after supper.

**A Normal Saline "Bomb,"** consisting of a cylindrical glass vessel having sealed tapering ends, is described by Dr. Brenner, in a recent number of the *Monatsschrift medizinische Wissenschaft* (1908, p. 188). This vessel has a capacity of 350 c.c. and is filled with sterile 0.6 per cent. salt solution, suitable for external or hypodermatic use. The "bomb" is of such a shape that it is easily packed for transportation, and may be heated to the proper temperature for use by placing it in hot water, the temperature being controlled by means of a bath thermometer. Other fluids intended for infusion may be put up in the same manner.

# NEW YORK MEDICAL JOURNAL

INCORPORATING THE

Philadelphia Medical Journal  
and The Medical News.

*A Weekly Review of Medicine.*

SUBSCRIPTION PRICE:

Under Domestic Postage Rates, \$5; under Foreign Postage Rate,  
\$7; single copies, fifteen cents.

Remittances should be made by New York Exchange or post  
office or express money order payable to the A. R. Elliott Pub-  
lishing Co., or by registered mail, as the publishers are not  
responsible for money sent by unregistered mail.

Entered at the Post Office at New York and admitted for  
transportation through the mail as second class matter.

NEW YORK, SATURDAY, JUNE 20, 1908.

## THE MEDICAL SERVICE OF THE NAVY.

In our department of Miscellany we publish this week almost the entire official circular of information for persons desirous of entering the Medical Corps of the United States Navy. We do so for the purpose of informing the younger of our readers concerning a most honorable career which is open to those of them who prove themselves worthy of entering upon it, because we are convinced that for the most part they must have overlooked its advantages. It is amazing that there should, in spite of those manifest advantages, still be fifty-four vacancies in the corps, though it is gratifying to know that the number is less than it was but a few months ago.

The surgeon general of the navy, Admiral Rixey, has, in his zeal for the welfare of the service and out of regard for the interests of our younger professional brethren, given out a printed statement of the attractiveness of life as a naval surgeon, and it is a "plain, unvarnished tale." The recent expansion of the navy and its prominence in the thoughts of the public, says Admiral Rixey, may or may not have stirred young medical graduates to think of the naval service as an opening for their professional career; but, whether they have or have not, it seems to him certain that such graduates are not fully apprised of the facts. He says of the medical officer of the navy that he "is vested with proper authority, receives unstinted praise and admiration, as in civil life, wherever and whenever merited, and

fills a position socially, professionally, and officially which self respect approves." He is a ward room officer, he continues, as soon as he enters the service, and his personal accommodations are as good as those of any of his brother officers, and represent comfort.

The naval medical officer's professional opportunities, says the surgeon general, are liberal, affording him time for following the practice of the great civil hospitals and clinics when his station is favorable, also liberty to engage in private practice to any extent not inconsistent with the performance of his official duties, and in this field many naval surgeons have added considerably to their income and to their reputation. In the great ports of the world, moreover, naval medical officers are freely received in the highest circles of society and view civilization from standpoints unattainable at home, and they have facilities denied to others for studying diseases and sanitary conditions which the civilian is debarred from observing.

In civil life the young graduate, already often almost impoverished by the cost of his professional education, has to make a considerable additional outlay for quarters and appliances at his very entrance on the tedious period of waiting for patronage. All this he escapes in the public service, where everything necessary is furnished by the government. At an age when his faculties and his capacity for enjoying life are still as a rule not sensibly impaired he is retired for the rest of his existence on remuneration reduced by only a quarter of his highest pay. Surely one would think that the career of a naval surgeon would prove alluring to a great number of young medical men.

## A NEW OPPORTUNITY FOR PSYCHIATRY.

THAT most baffling of all branches of medicine, psychiatry, dealing with the disorders of the most highly evolved and most important organ of the body, the brain, has finally come to its own. The all wise Greeks clearly grasped the essential fact that mental disorders were brain disorders, but for a thousand years or so the cobwebs of metaphysics have been spinning and obscuring men's minds to the obvious truths of cerebral mechanisms.

The extreme complexity of anatomical formation of the as yet incompletely analyzed brain structure has been an important factor in preventing psychiatry from assuming an authoritative position among its many sister branches, but it would seem that with the advances made by such anatomists as Golgi, Cajal, Van Gehuchten, Dejerine, Nissl, Alzheimer, Doziel, and Bielschowsky, such clinicians as Wernicke, Ziehen, Kraepelin, Tanzi, Head, Bi-

anchi, Jackson, Freud, Magnan, and Meyer, and such physiologists as Wundt, Munk, Luciani, Flechsig, Sherrington, Bechterew, and Lewandowsky, not to mention scores of others, psychiatry had reached a point when fundamental correlations are a reality and will remain for all time. It is therefore a welcome sign that this advanced position has been appreciated by men of enlightenment and public spirit, and embodied in a tangible gift to one of our foremost universities.

The gift of \$750,000 by Mr. Henry Phipps to Johns Hopkins University, for the foundation of a psychiatric clinic, will serve a threefold interest. In the first place, it will be the mental ward of the general hospital, in which patients may be received for treatment without the formality of commitment, and without the stigma that attaches itself to patients with mental trouble, a relic of the days of superstition and idolatry, when the mentally ill needed to have devils cast out of them; secondly, it will afford opportunities for instruction in this vast and much neglected field of medicine; and finally, by reason of the rich endowment, laboratories for research will afford unusual opportunities for the carrying out of the extremely technical studies that work in this field requires.

It is a subject for much congratulation that through such a gift the importance of mental disorders is emphasized. There is no field of preventive medicine that can reap such fruit as that of psychiatry. We have struggled for years to save legs, to patch up internal organs, to keep out and subdue infections; now is the time to reap a rich harvest in saving the mental powers of mankind. Is there a way to lessen crime, to limit the outlay of the public money in caring for the thousands of dependents, the idiots, imbeciles, demented, and chronic mentally ill? If there is, it will come about only by the better recognition of the mental factors which bring about such conditions. The new psychiatric clinic will serve as a useful beginning in this line, and we confidently look forward to the time when others will see the needs as Mr. Phipps has seen them, and respond to the call.

#### THE HEALTH OF THE PHILIPPINE ISLANDS.

In our news columns we recently published some figures taken from the annual report of the Bureau of Health of the Philippine Islands. The report, made by Dr. Victor G. Heiser, the director of health, contains some interesting statements outside of the purely statistical portion from which our figures were taken. These figures apply, as would be supposed, to the city of Manila, the agricultural and

mountainous districts of the archipelago not yet having been sufficiently organized to furnish reliable statistics. The report shows that, while the death rate to a thousand of population was 36.91, the sanitary reforms inaugurated in the city and carried out for the past few years are beginning to show results. The public health was more satisfactory during 1907 than at any previous time during the American occupation. In 1906 the death rate was 40.9 in a thousand. But the death rate for Americans shows even more gratifying figures; in 1906 it was 9.34; in 1907, 5.59 to a thousand of the population.

There has not been a single case of plague in the islands; there has not been one death from smallpox in Manila; cholera in recognizable form has disappeared; provinces in which formerly there had been 6,000 deaths annually from smallpox have not reported a single death from the disease, and this is the result of over 2,000,000 vaccinations. The number of lepers on September 1, 1905, was 3,580; the number on June 30, 1907, was 2,282.

The report takes up the various epidemic diseases in detail and describes the methods adopted by the Bureau of Health for their elimination. The smallpox campaign really shows the most striking results, although the cholera work is worthy of some comment and of sincere congratulation to those engaged in its conduct. At the time that the last annual report was sent to the press the authorities were engaged in handling an epidemic of cholera which threatened to assume serious proportions. The epidemic spread principally by land, both north and south. The measures adopted for the suppression of the epidemic were strict outgoing maritime quarantine, prompt isolation of the sick, and disinfection of premises, with no attempt at land quarantine. The discontinuance of a land quarantine is a feature that the health authorities of Manila are to be congratulated upon having courage to adopt. We are strongly of the opinion that land quarantine is of no value in preventing the spread of transmissible diseases, and that the important thing is to isolate the infected individual. In regard to this feature of the cholera campaign, Dr. Heiser says: "It is hardly possible to describe the feeling of security which seemed to pervade the public. With the exception of the comparatively small increase in the freight and passenger rates that was imposed upon interisland vessels leaving Manila, no large financial loss resulted. The regular machinery of the Bureau of Health worked so smoothly that it was able to meet all demands with practically no increased outlay above routine expenditures. If it had not been for the reports published daily, the people would scarcely have known that cholera was in

their midst, except in so far as they or their friends were directly affected by the disease. The feeling of security was directly responsible for the preservation of many lives, and, on account of there having been practically no disturbance to business, thousands of dollars were saved."

At the San Lázaro Hospital twenty-nine cases of leprosy have been treated with the x rays. Eight patients were very decidedly improved, thirteen were considerably improved, seven showed no change, and one died. The officials of the hospital intend to continue the experiments with this form of energy in the treatment of leprosy.

### POPULAR INSTRUCTION IN NURSING.

The Chautauqua School of Nursing, an institution which has its headquarters in Jamestown, N. Y., is undoubtedly doing a most excellent work, that of fitting young women for the profession of nursing in greater numbers than could be accommodated in the regular hospital training schools and without subjecting them to conditions which many of them might find onerous. The teaching is chiefly by means of printed lectures issued to the pupils. We have examined these lectures, which cover the whole range of medical, surgical, and obstetrical nursing, and they seem to us admirably adapted to their purpose. The necessary lack of personal demonstrations is in a great degree compensated for by ingenious engravings. The school does not content itself with furnishing this literature to its pupils, but requires them to fill out examination blanks which are so devised as to afford practical tests of the pupils' comprehension of the lectures. The school also prints for the use of the young women a number of narratives of the experiences of their predecessors who have completed the course, written by themselves. These also we have examined, and they have appealed to us as the productions of very intelligent and conscientious women, women who do not disdain to serve among the lowly and at rates of compensation which the poor can for the most part afford, or even wholly as a work of charity in case of need, in remote rural places. Such nurses are sorely needed by the overworked country practitioner and his patients, and it was this need that was the special incentive to the establishment of the school.

### PROVOKED ERUCTATION AS A REMEDIAL MEASURE.

In the *Semaine médicale* for June 3d we read that an Austrian physician, Dr. Max Herz, of Vienna, has succeeded in mitigating the painful attacks incident to cardiac disease, such as angina pectoris,

also paroxysms of tachycardia, by the expedient of causing the patient to belch up wind from the stomach. He has even prevented these attacks when the eructation was brought about early enough, at the time of the premonitory sensations. He attributes the efficiency of the procedure to the fact that the heart and the stomach are both innervated by the pneumogastric nerve.

Eructation is produced by the following procedure: The patient, seated, takes a small drink of water and holds it in his mouth. He then throws his head as far backward as possible and swallows the water. The posture is such as to stretch the œsophagus and induce in the pharynx a sensation which causes eructation, provided that result is not voluntarily prevented by the patient. It is well to warn the person that an eructation is desired; otherwise he may restrain it out of a sense of decency. Herz had observed the relief afforded by spontaneous belching, but it is not explained how he was led to devise the manœuvre for imitating it.

### A PROPOSED SCHOOL OF SANITARY SCIENCE.

The *Columbia University Quarterly* has issued a supplement of seventy pages devoted entirely to an essay entitled *Education and its Economic Value in the Field of Preventive Medicine; the Need for a School of Sanitary Science and Public Health*, by Dr. Norman Edward Ditman. Dr. Ditman depicts very graphically the ravages of preventable disease and their mitigation by preventive measures. One need not agree to all that is said in the essay to join with the author in his main contention that there is great need in this country of a school, one at least, for the diffusion of knowledge in regard to sanitary problems and their solution.

Dr. Ditman would have a school of preventive medicine planned to give instruction to students preparing for the practice of medicine, for offices of health boards and as sanitary inspectors, for sanitary engineering (civil, military, and naval), for work as school and college teachers, school nurses, or school inspectors, for work as officers of charity societies and institutions, visiting nurses, and "social workers," for the ministry, and for legislative work, also to the public. He specifies more than thirty subjects which he would have taught, mentioning also the groups of persons to whom the branches should be taught. There are at present courses in nearly half these branches in Columbia University. He would have medical students instructed in all these branches save the last, domestic science, which, indeed, as we understand his tabular statement, he does not recommend for anybody, al-

though it is set down among those already taught in Columbia. We fancy that in this particular the table has been incorrectly printed.

There can be no doubt that all the subjects mentioned should be taught to various classes of the community, especially to medical students, but it is questionable whether the teaching should be done in a special institution or in a department of a university. It would be in the interest of economy, it may be supposed, to have it done in a university, not as an integral part of the medical curriculum, but with all the students of the medical school privileged to attend the courses.

### News Items.

**Changes of Address.**—Dr. Isaac H. Jones, to 4501 Spruce Street, Philadelphia.

**The Hampden District, Mass., Medical Society** held its annual meeting in Springfield recently and elected the following officers: President, Dr. George L. Woods, of Springfield; vice president, Dr. C. W. Jackson, of Monson; secretary and treasurer, Dr. R. S. Benner, of Springfield.

**Society Meetings for the Coming Week:**

**Thursday, June 25.**—Buffalo Academy of Medicine (Section in Obstetrics and Gynecology).

**Thursday, June 25.**—New York Gynecological Society, Brooklyn Society for Neurology.

**Saturday, June 27.**—Harvard Medical Society.

**Contagious Diseases in Chicago.**—The following cases of communicable diseases were reported to the Bureau of Contagious Diseases during the week ending June 6, 1908: Measles, 269; scarlet fever, 63; diphtheria, 61; chickenpox, 36; tuberculosis, 21; whooping cough, 20; typhoid fever, 16; smallpox, 1; diseases of minor importance, 4; total, 491.

**Officers of the Massachusetts Medical Society.**—At the annual meeting of this society, which was held in Boston during the week of June 8th, the following officers were elected: President, Dr. Silas D. Presbrey, of Taunton; vice president, Dr. D. E. Keefe, of Springfield; secretary, Dr. E. W. Goss, of Roxbury; treasurer, Dr. G. M. Buckingham, of Boston.

**L'Association des Médecins de langue française de l'Amerique du Nord.**—The annual meeting of the association of French speaking physicians of North America will be held in the city of Quebec on the occasion of the centennial anniversary of the founding of the city. The sessions will be held in the buildings of Laval University on July 20th, 21st, and 22d.

**Scientific Society Meetings in Philadelphia for the Week Ending June 27, 1908.**—*Monday, June 22.* Philadelphia County Medical Society. *Tuesday, June 23.* Philadelphia Academy of Natural Sciences. *Wednesday, June 24.* Academy of Natural Sciences; Section Meeting, Franklin Institute. *Friday, June 26th.* South Branch, Philadelphia County Medical Society; Northern Medical Association; Philadelphia Neurological Society.

**A Campaign Against Bovine Tuberculosis.**—Governor Hendon has issued an order, which gives the New York State Department of Agriculture authority to campaign against bovine tuberculosis. Appropriations aggregating \$10,000 are available for the work. Included in this sum is an appropriation of \$7,000 made at the recent session of the legislature, to be used in payment for cattle so furnished by the department.

**The Medicochirurgical College of Philadelphia** held its annual commencement exercises on Saturday, June 13th. The degree of doctor of medicine was conferred on one hundred and fifty-two men. Dr. Henry C. Phillips presented the Dr. Samuel Morris prize and the faculty gold medal for the highest general average in the graduating class. Dr. Hudson Perry, Welch, vice president of the Pennsylvania State College, delivered the oration.

**Elmira, N. Y., Academy of Medicine.**—At a meeting of this academy, held on Wednesday evening, June 3d, Dr. R. P. Bush, of Horseheads, N. Y., read a paper on Endocarditis, and Dr. Alexander Mark, of Elmira, N. Y., read a paper on Diagnosis of Children's Diseases.

**Association of Ex-Resident Physicians of St. Joseph's Hospital, Philadelphia.**—At a recent meeting of this association permanent organization was effected, and officers for the ensuing year elected as follows: President, Dr. George Morley Marshall; vice president, Dr. David Moylan; historian, Dr. Joseph Roberts; secretary and treasurer, Dr. Joseph M. Spellissy.

**American Urological Association.**—A stated meeting of the New York Society was held in the New York Academy of Medicine on the evening of Wednesday, May 27th. The paper of the evening was read by Dr. G. Morgan Muren on Real Conservatism in the Treatment of the Prostate. Among those who took part in the discussion were Dr. Eugene Fuller, Dr. L. Bolton Bangs, and Dr. Follen Cabot.

**Medicochirurgical Society of Central New York.**—At the annual meeting of this organization, which was held in Syracuse recently, the following officers were elected for the ensuing year: President, Dr. C. T. Haines, of Utica; first vice president, Dr. W. H. Sweeting, of Savannah; second vice president, Dr. C. W. Radway, of Medico; secretary and treasurer, Dr. George J. Gannette, of Syracuse.

**Obstetrical Society of Philadelphia.**—At a stated of this society, which was held on Thursday evening, June 4th, the programme included the following papers: Uncontrollable Hemorrhage Associated with Diseases of the Uterine Wall, by Dr. Brooke M. Anspach; The Early Diagnosis of the Cancer of the Uterus, by Dr. R. F. Woods; Rupture of the Uterus, with Report of Two Cases, by Dr. Frank C. Hammond.

**Southwestern Kentucky Medical Society.**—At the annual meeting of this society, which was held in Paducah recently, the following officers were elected for the ensuing year: President, Dr. Vernon Blythe, of Paducah; first vice president, Dr. H. T. Crouch, of Bardwell; second vice president, Dr. L. W. Ogilvie, of Birmingham; secretary, Dr. C. E. Purcell, of Paducah; treasurer, Dr. C. H. Brothers, of Paducah; and historian, Dr. R. T. Hoeker, of Arlington.

**Missouri State Medical Society.**—At the annual meeting of this society, which was held in Springfield recently, the following officers were elected for the ensuing year: President, Dr. A. R. Kieffer, of St. Louis; secretary, Dr. A. W. McAllister, Jr., of Kansas City; treasurer, Dr. J. F. Walsh, of Salisbury. Dr. R. L. Goodier, of Hannibal, was elected orator in medicine, and Dr. F. J. Lutz, of St. Louis, orator in surgery. Jefferson City was chosen as the next meeting place.

**The West Virginia State Medical Association.**—At the annual meeting of this society, which was held recently at Clarksburg, the following officers were elected: President, Dr. Fleming Howell, of Clarksburg; president elect, Dr. V. T. Churchman, of Charleston; first vice president, Dr. R. J. Reed, of Wheeling; second vice president, Dr. R. S. Powell, of Grafton; third vice president, Dr. H. D. Hatfield, of Elchman; secretary, Dr. T. C. Moore, of Huntington; treasurer, Dr. T. L. Barber, of Charleston.

**Gift to the Garfield Memorial Hospital, Washington, D. C.**—Dr. Loren B. T. Johnson, of Washington, has donated to the trustees of the hospital an amount of \$10,000 for the erection of an annex to the hospital as a memorial to his wife. The annex is to be devoted exclusively to the care of women patients. It is proposed to place a tablet in some suitable place in the building to indicate his purpose in erecting it. The proposed annex will be called the Johnson Building.

**Officers of the Tennessee State Medical Association.**—At the annual meeting of this association, which was held recently, the following officers were elected to serve for the ensuing year: President, Dr. H. D. Knapp, of Knoxville; vice president for East Tennessee, Dr. C. T. Carroll, of Clarksville; vice president for West Tennessee, Dr. M. A. Raper, of Memphis; secretary, Dr. J. W. Brainerd, of Clarksville; treasurer, Dr. George H. Price, of Nashville; Dr. W. C. Bollen, of Memphis, historian.

**The Health of Pittsburgh.**—During the week ending June 6, 1908, the following cases of transmissible diseases were reported to the Bureau of Health: Chickenpox, 5 cases, 0 deaths; typhoid fever, 26 cases, 4 deaths; scarlet fever, 12 cases, 0 deaths; diphtheria, 8 cases, 0 deaths; measles, 230 cases, 7 deaths; whooping cough, 7 cases, 1 death; pulmonary tuberculosis, 30 cases, 10 deaths. The total deaths for the week numbered 144, in an estimated population of 403,330, corresponding to an annual death rate of 18.56 in 1,000 of population.

**Medical Society of the Woman's Hospital of Philadelphia.**—At a regular meeting of this society, held on Monday evening, June 15th, the following papers were read: Review of Our Present Knowledge of the Physiology of Digestion, by Dr. Martha Tracy; Acute Dilatation of the Stomach associated with Operation, by Dr. Ellen C. Peiter; Perforation of the Uterus, with a Report of Two Cases, by Dr. Sarah H. Lockrey; Report of the 1908 meeting of the International Congress of Laryngologists, by Dr. Margaret F. Butler.

**Philadelphia County Medical Society.**—At a meeting of the Central Branch of this society, which was held on the evening of Wednesday, June 10th, Dr. F. A. Faught and Dr. J. F. Dever gave a demonstration of a device for facilitating test meal removal and gastric lavage. A paper entitled Fibroid Tumors of the Uterus Complicating Pregnancy was read by Dr. Wilmer Krusen and discussed by Dr. Barton Cooke Hirst, Dr. Charles P. Noble, Dr. J. M. Baldy, and Dr. Swithin Chandler. Dr. E. J. Gillespie Beardsley read a paper on the Anamnesis of Subjects of Exophthalmic Goitre.

**The Jefferson Medical College of Philadelphia** held its eighty-third annual commencement on Monday, June 8th. One hundred and seventy men received the degree of doctor of medicine. Dr. William H. Howell, dean of the medical faculty and professor of physiology in the Johns Hopkins University, delivered the oration. Two prizes of \$75 each, awarded upon recommendation of the professor of medicine and of the professor of surgery to the student in each branch considered the most worthy, were awarded to Dr. Joseph Lloyd Warne and to Dr. George Elmer Krout, respectively.

**Charitable Bequests.**—By the will of Mrs. Jerome H. Jones, the Brookline, Mass., Free Hospital for Women receives \$10,000; the Industrial School for Crippled and Deformed Children, Boston, receives \$10,000; the Children's Hospital, Boston, receives \$10,000; and the Home for Aged Couples, Boston, receives \$5,000.

By the will of George Bliss Griggs, the Springfield, Mass., Hospital receives \$10,000.

By the will of Letitia Bentz the Little Sisters of the Poor receive \$250, and St. John's Orphan Asylum and St. Agnes's Hospital, Philadelphia, receive \$100 each.

**The Annual Convocation of the Medical Faculty of McGill University, Montreal,** was held on the afternoon of June 12th. Eighty-six students received the degree of M. D., C. M. The degree of LL. D. was conferred upon Dr. Edward Albert Schäfer, professor of physiology at the University of Edinburgh, who made a brief address. The annual address to the graduates was delivered by Professor T. A. Starkey, M. B., D. P. H., Fellow of the Royal Sanitary Institute, and the class valedictory was read by Dr. Donald F. Macdonell. Dr. Thomas G. Roddick announced his resignation as dean of the faculty, and the appointment of Professor F. J. Shephard as his successor.

**The Burlington County, New Jersey, Medical Society.**—The regular meeting of the Burlington County Medical Society was held at Morristown, N. J., on Wednesday, June 10th. Dr. Ernest Laplace, of the Medico-Chirurgical College, read a paper on the Significance of Pain in Abdominal Diagnosis. Dr. John M. Swan, of the Philadelphia Polyclinic, read a paper on the Diagnostic Significance of Leucocytosis. Dr. L. Napoleon Boston, of the Medico-Chirurgical College, read a paper on Bacteriemia following Surgical Conditions and in Acute Fevers. There was a short discussion on Hydrophobia. A dinner followed the scientific business of the meeting. About twenty-five members and guests were present.

**Cornell University Medical College** held its tenth annual commencement on June 10th. The degree of doctor of medicine was conferred on fifty-eight graduates, among whom was one woman, Miss Phoebe Lott Du Bois, of Freehold, N. J. The prize winners were Dr. Willis Gaylord Graves, of Binghamton, N. Y.; Dr. Rodney Ralph Williams, of Fredonia, N. Y.; Dr. Harry Clifton Luke, of Salamanca, N. Y.; Dr. Harold Elmore Santee, of Hornellsville, N. Y.; and Dr. Harold de Wolf, of Bristol, R. I. Dr. J. G. Schurman, president of Cornell University, delivered the address. The commencement exercises were followed by the annual banquet of the Cornell Medical Alumni Association at the Hotel Manhattan.

#### Infectious Diseases in New York:

*We are indebted to the Bureau of Records of the Department of Health for the following statement of new cases and deaths reported for the two weeks ending June 13, 1908:*

	—June 6.—		—June 13.—	
	Cases.	Deaths.	Cases.	Deaths.
Tuberculosis pulmonalis	440	161	409	189
Diphtheria	268	25	353	37
Measles	1,432	17	1,031	21
Scarlet fever	498	22	513	27
Smallpox	..	..	..	..
Varicella	74	..	122	..
Typhoid fever	45	7	35	5
Whooping cough	25	5	25	4
Cerebrospinal meningitis	7	5	7	4
Totals	2,776	242	2,486	278

**School of Instruction for Health Officers.**—The tenth annual course of instruction for the health officers of the State of Vermont will be held in Burlington on June 29th to July 2d, inclusive. All health officers of the State are required to attend the sessions of this school, and no one will be excused for nonattendance except in case of illness. The public are invited to attend. According to the provisional programme, which we have just received, the first session will be held on Monday, June 29th, at 8 p. m., when addresses will be delivered by Dr. Charles S. Caverly, president of the State Board of Health; the Hon. F. D. Proctor, Governor of the State; the Hon. Walter J. Bigelow, Mayor of Burlington, and Judge Edward C. Mower, of Burlington. There will be three sessions daily on Tuesday and Wednesday, at 9:30 a. m., at 2 p. m., and at 8 p. m., and the final session will be held on Thursday morning at 9 o'clock.

**A Psychiatric Clinic for Johns Hopkins Hospital.**—Dr. William H. Welch, of Johns Hopkins University, announces that Mr. Henry Phipps, of Pittsburgh, has arranged for a large gift to the Johns Hopkins Hospital and University for the founding of a psychiatric clinic on the lines of well known similar institutions in Europe. The total amount of the gift is withheld in accordance with the wishes of Mr. Phipps, but it is understood that it will exceed half a million dollars. The funds provide for the erection of a four story building, with accommodations for sixty patients, with rooms for private patients. The building will be equipped with all the most modern appliances and apparatus for use in the treatment of patients, and laboratories for scientific investigation of the nature, cure, and prevention of mental diseases. Provision has also been made for the establishment of a professorship of psychiatry at the university, the professor to be the director of the clinic.

**The American Academy of Ophthalmology and Otolaryngology.**—The thirteenth annual meeting of this organization will be held in Cleveland, Ohio, on Thursday, Friday, and Saturday, August 27, 28, and 29, 1908. The preliminary programme of the Oto-Laryngological Section includes sixteen papers on subjects relating to diseases of the throat and ear, and a symposium on the past, present, and future of oto-laryngological teaching. More than twenty papers have been promised for the Section in Ophthalmology, exclusive of a symposium on ophthalmic pedagogy. The officers of the society are: President, Dr. Derrick T. Vail, of Cincinnati; first vice president, Dr. Joseph C. Beck, of Chicago; second vice president, Dr. Theodore B. Scheidman, of Philadelphia; third vice president, Dr. F. S. Owen, of Omaha; treasurer, Dr. Otto J. Stein, of Chicago; secretary, Dr. George F. Suker, of Chicago; chairman of the committee on arrangements, Dr. Second H. Lutz, of Cleveland.

**The Mortality of Chicago.**—During the week ending June 6, 1908, there were reported to the Department of Health of the City of Chicago 483 deaths from all causes, as compared with 578 for the previous week and 574 for the corresponding period in 1907. The annual death rate in 1,000 of population was 11.63, which comes close to the lowest rate ever recorded in Chicago at this time of the year. The principal causes of death were: Apoplexy, 8; Bright's disease, 35; bronchitis, 13; consumption, 63; cancer, 26; convulsions, 1; diphtheria, 7; heart diseases, 40; influenza, 2; intestinal diseases, acute, 29; measles, 5; nervous diseases, 19; pneumonia, 42; scarlet fever, 5; suicide, 10; violence (other than suicide), 52; whooping cough, 1; all other causes, 125.

**Vital Statistics of New York.**—During the week ending June 6, 1908, there were reported to the Department of Health of the City of New York 1,222 deaths from all causes, as compared with 1,434 for the corresponding period in 1907. The annual death rate in 1,000 of population was 14.41, in an estimated population of 4,422,685. Of the five boroughs, Manhattan had the highest death rate, 15.20 in 1,000 of population, while the Bronx came second with a death rate of 14.81. The death rate of Brooklyn for the week was 13.49, that of Queens was 12.11, the lowest for the five boroughs, and of Richmond, 14.20. Of the total number of deaths 668 were in Manhattan, 93 in the Bronx, 386 in Brooklyn, 54 in Queens, and 21 in Richmond. The total infant mortality was 307; 242 under one year of age, and 65 between one and two years of age. There were 144 still births. Seven hundred and thirty-five marriages and 3,008 births were recorded during the week.

**American Climatological Association.**—The twenty-fifth annual meeting of this organization took place in Boston on June 9th, 10th, and 11th. The attendance was large, members being present from all parts of the United States, and all agreed that the meeting was one of the best ever held by the association. The scientific programme, which was one of unusual interest, included a number of papers dealing with the treatment of tuberculosis. The newly elected officers are: President, Dr. Charles E. Quimby, of New York; first vice president, Dr. Edward R. Baldwin, of Saranac Lake, N. Y.; second vice president, Dr. Carroll E. Edson, of Denver, Col.; secretary and treasurer, Dr. Guy Hinsdale, of Hot Springs, Va.; council, Dr. James C. Wilson, of Philadelphia; Dr. W. F. R. Phillips, of Washington, D. C.; Dr. E. L. Shurly, of Detroit; Dr. Thomas Darlington, of New York; and Dr. Thomas D. Coleman, of Augusta, Ga.; delegate to the council of the congress at Washington in 1910, Dr. Frederick T. Knight, of Boston, with Dr. Roland G. Curtin, of Philadelphia, alternate.

**Rules Governing the Use of the Library of the New York Academy of Medicine.**—We present herewith extracts from the rules governing the use of the library of the New York Academy of Medicine by others than members of the academy.

**Bylaw XIII. Section 7.** Candidates for fellowship, after announcement by the committee on admission, may be granted the privilege of the library on the payment of a fee of \$20 a calendar year or pro rata in advance. The amount so paid in a given calendar year shall be refunded from the candidate's admission fee if he be elected to fellowship in a calendar year for which the fee was paid.

**Section 8.** Any person approved by the library committee and by the council may become an associated reader on such conditions as the council may impose. Associated readers shall be entitled to a card giving the privileges of the library, good for one year from the date of their acceptance.

**Section 9.** The privilege of consulting the library, but not of taking out books, may be granted for one month, when authorized by a card signed by the executive librarian or his representative, on written request by the applicant, to accredited representatives of fellows of the academy on application by the latter. No one shall be introduced under the provision of this section more than once in six months, except by special permission of the council.

**Section 18.** The library shall be open to the public from 9 a. m. to 6 p. m. Fellows and persons included in Sections 7, 8, and 9 shall have access to the library from 9 a. m. to 6 p. m.

The fee of general subscription, \$100.00, is paid in advance.

### THE BOSTON MEDICAL AND SURGICAL JOURNAL.

June 11, 1908.

1. On Some Relations of the Physician to the Public. Duties and Opportunities.  
By WILLIAM SYDNEY THAYER.
2. Modern Medicine and Surgery in the Orient (to be continued).  
By J. EWING MEARS.
3. Modes of Infection in Tuberculosis.  
By SILVIO VON RUCK.
4. Composition of Large Curds in Infants' Stools.  
By FRITZ B. TALBOT.
5. Camphoric Acid, Its Action and Uses.  
By MAURICE VEJUX TYRODE.

3. **Modes of Infection in Tuberculosis.**—Von Ruck reviews our present knowledge of the modes of infection in tuberculosis: As concerns the tuberculosis of animals as a source of infection, it is with food products that we have chiefly to deal, especially with meat and milk. The possibility of such infection has at no time been denied, but the question of its frequency has given rise to varied opinions, and in recent years has become of renewed interest as the result of Professor Koch's announcement, at the London Congress, of the nonidentity of the human and bovine type of bacillus, and of his conviction that the tuberculosis of these respective species is not readily communicated from the one to the other. The question has not been settled, and we have to wait until more accurate study in the isolation of cultures and experimental proof of their respective virulence affords reliable data. Since 1902 such investigations at Koch's suggestion have been vigorously prosecuted at the German Imperial Health Bureau and also by others. Up to the present time the cases in which bovine infection has been proved to have occurred in man are but thirty-three in number, eighteen of which have been examined at the German Imperial Health Bureau, while fifteen are reported by other observers. There are three groups of infections: Infections of directly accessible surfaces, which may be termed local or contact infection; infection through the air by inhalation; and infection through food by ingestion. To the group of local infections belong all cases of skin tuberculosis and the majority of the primary cases of tuberculosis of the mucosa of the several orifices of the body. In these cases the tendency is for the disease to remain localized unless in young children, in whom the contrary is true, as is shown by cases of tuberculous infection during ritual circumcision, when generalization appears to be frequent. Occasional cases of accidental infection of the hands at autopsies of tuberculous subjects are known. Cases of local infection after piercing the lobule of the ear for earrings, after the use of an infected hypodermic syringe, after tattooing, and after similar slight wounds are to be found in the literature. Occasional tuberculous infection of surgical wounds occurs. It has frequently been both asserted and denied that tuberculosis may be conveyed by vaccination, but vaccine, the lymph from tuberculous cattle, and the contents of vesicles in the arms of human subjects have been repeatedly examined for the presence of tubercle bacilli with negative results. Even in arm to arm vaccination, if the person furnishing the lymph was tuberculous, the tubercle bacilli would be present in the blood before they can pass into the vaccinee.

tents of the vaccine pustule, and even then the probabilities would still be against infection, unless present in considerable numbers. The mode of infection by inhalation is the one in which all the older authors believed, who held consumption to be contagious. Especially is this the case with sputum droplets. The distance to which such droplets are projected is usually stated to be about three feet, although Engelmann found it one and a half metres, while Bing found bacilli at a distance as great as three metres, and Fluegge found that under artificial conditions they could be projected even as far as ten metres. The degree of danger attaching to droplet infection has thus been variously estimated, but the writer is not inclined to consider suspended droplets as the most important source of infection. Such droplets do not remain suspended indefinitely, and most of them must gravitate immediately. It is when deposited in the form of dust or from dust containing tubercle bacilli that the greatest danger exists, although the danger is not to be minimized. The third group is the most important one, the infection of the digestive tract by ingestion of tubercle bacilli. It is possible that food may serve as a medium for infection with the bacilli of human type, but the probability that enough bacilli are introduced by its contamination with infectious dust or droplets in its preparation by consumptives, or that flies are likely to play an important part by transferring tubercle bacilli from sputum to food, would seem slight, and especially so if alimentary infection of the human subject conforms to the experience we have with the lower animals, in which enormous quantities of tubercle bacilli must be fed to produce a positive result. That the human subject is not an exception in this respect is indicated by the infrequency of primary infections of the intestine, and, moreover, by the clinical fact that the autoinfection of the digestive tract is, as a rule, an occurrence deferred to the advanced stages of pulmonary phthisis. Of greater importance for primary infection of the digestive tract appears the inhalation of infectious dust and its deposit in the pharynx or the mouth, whence it is swallowed with mucus and saliva, and with food and drink. It undoubtedly occurs, it is more frequent in children than in adults, and the origin of tuberculosis in the abdominal cavity appears to be less frequent than it is in that of the chest. The author also mentions the contention of Behring that practically all tuberculous infections in man are due to feeding the milk of tuberculous cows to nurslings as a substitute for mother's milk. Behring has even gone so far as to announce that not a single case of epidemiological human infection has been proved.

#### THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

June 15, 1908.

1. State's Right and the National Health. Oration on State Medicine at the Fifty-ninth Annual Session of the American Medical Association, at Chicago, June 2-5, 1908. By CHARLES HARRINGTON.
2. Indolaceturia. By C. A. HERTER.
3. Streptococcal Infections of the Pharyngeal Adenoid Tissue in Adults. By ALICE G. BRYANT.
4. Laryngeal Manifestations in Locomotor Ataxia and Multiple Sclerosis. By WOLFF FREUDENTHAL.
5. The Phorbiden Test, with Special Reference to the In-

fluence Exerted by a Diseased Kidney on the Excretory Work of the Second Organ. By EDWIN BEEER.

6. An Epidemic of Cerebrospinal Meningitis. Successful Use of Flexner's Antiserum. By AUSTIN MILLER and S. A. BARBER.
7. Arthritis Deformans of the Hip. Preliminary Report of a New Operation. By FRED H. ALBEE.
8. The Eye as a Contributing Factor in Tuberculosis. By F. PARK LEWIS.
9. Ocular Reaction to Tuberculin. By FREDERICK TICE.

2. **Indolaceturia.**—Herter points out that it appears probable that the excessive feeding of proteins may be concerned with the development of indolaceturia. But indolaceturia appears also in persons who are taking no excess of protein food. Moreover, in pathological cases of indolaceturia, in which the protein food has been restricted, the indolaceturia may be still persistent. It is thus clear that, while the intake of a large amount of protein is a factor highly favorable to the development of indolaceturia, the occurrence of this condition must be regarded as depending rather on delayed absorption of tryptophan and suitable bacterial conditions than on mere over feeding with proteins. Assuming that both indolacetic acid and the indol formed in the intestinal tract are derived from tryptophan through the action of bacteria, the fact remains still to be accounted for that sometimes the decomposition of tryptophan yields mainly indolacetic acid and at other times mainly indol. As is well known, bacteria of the *Bacillus coli* group are capable of clearing tryptophan to indol and that these organisms are able to form indolacetic acid from tryptophan. It is doubtless true that in the intestinal tract the bacteria associated with the colon bacilli play a part in determining the direction of the main cleavage of tryptophan, and I think it possible that through the careful study of the symbiotic action of bacteria on this substance it will be possible to gain an insight into the different bacterial conditions that determine the production of indolacetic acid rather than indol.

4. **Laryngeal Manifestations in Locomotor Ataxia and Multiple Sclerosis.**—Freudenthal concludes that the larynx is frequently the seat of serious affections in tabetics. Laryngeal crises are met with so often that they are almost of pathognomonic significance. Unilateral and bilateral paralysis of the postici muscles are the affections par excellence in tabetics, but a unilateral paralysis of the recurrent nerve, often with the vocal cord in a hyperabducted position, as mentioned by Harland, is nothing uncommon. The abductor fibres of the recurrent laryngeal nerve are affected primarily in tabes as well as in multiple sclerosis. The voice in tabetics is often not changed, in spite of advanced lesions. In order to reach a positive diagnosis all these cases have to be observed during a considerable period. In multiple sclerosis there is frequently present a subjective dyspnea that can not be explained by the objective signs.

7. **Arthritis Deformans of the Hip.**—Albee describes his method of operation, which he has used in five cases: The hip joint is reached by an anterior incision five inches long, through skin and subcutaneous tissues, starting from just below and inside of anterior superior spine of the ilium, and extending

downward along the inner border of the sartorius muscle, which is retracted outward. The muscles and the deep structures are separated by blunt dissection and the iliacus and the rectus femoris muscles are retracted inward. A part of a large ring of osteophytes about the rim of the acetabulum is turned upward with the soft tissues adherent to them. With the head of the femur *in situ* about one half of its upper hemisphere is removed with a large chisel, through a plane nearly parallel to the long axis of the neck of the femur. Then with the same instrument the acetabulum is transformed into a flat surfaced roof against which the fresh surface of the head is finally brought into firm contact by abduction of the thigh. The bone is removed from the acetabulum so that the flat surface is tilted somewhat upward internally in order to produce, in a way, locking of the fragments and also to prevent any possibility of dislocation. Further abduction is impossible on account of the shortened abductors and an open tenotomy of these tendons and muscles, at their origins, is found necessary before the leg can be brought into proper position. The plain surfaces of the head and acetabulum are brought together by simply abducting the thigh. The capsule and soft tissues are then sutured. Access to the joint is much facilitated by a position of extreme adduction of the limb. For purposes of orientation an assistant is kept in constant readiness to rotate the femur when desired. The leg in strong abduction is finally put in a spica from axilla to toes. The patient upon whom this operation was performed made an uneventful recovery and was walking about with crutches at the end of four weeks. A short spica bandage was applied at the end of five weeks. At the end of nine weeks he was able to walk without cane or crutch and he went back to work as patrolman in four months. He states that he has not suffered any pain since operation. The leg has remained well in corrected position and only an extra lift of leather has been worn on the heel. His occupation since the operation vouches for his locomotive abilities. He has continued as a patrolman, working nine hours a day, and has not lost a day on account of his hip since he went back to work in September, 1907.

9. **Ocular Reaction to Tuberculin.**—Tice finds that as a diagnostic method Calmette's test is by no means positive or even specific. In a varying proportion of tuberculous cases of various forms a positive reaction will occur, but not in all. In distinctive diagnosis it can be of but limited service as it appears, apparently, in nontuberculous affections. When the subcutaneous use of tuberculin in doubtful cases of tuberculosis is not possible on account of fever the ocular test may be employed. In incipient cases in which an early positive diagnosis was most desired it was of no service. In a review of the literature no reference is made to the therapeutic possibilities in this method of administering tuberculin. The absorption by the conjunctiva is rapid and considerable, as can be demonstrated by the use of other drugs. Just what effect early administration of tuberculin has in the power of resistance as indicated by the opsonic index has not been determined. If the ocular reaction is con-

logous to the local or general reaction produced by subcutaneous injections of tuberculin, and it is found feasible to administer it in this manner, it may be found necessary to avoid the pronounced and severe reactions. As the reaction occurs apparently in patients in whom no tuberculosis can be demonstrated it may, like the reaction from subcutaneous use of tuberculin, belong to the "group reactions." From all we can now judge, the ocular reaction to tuberculin must be considered simply as confirmatory, and must always be considered secondary to the findings as determined by a careful physical examination.

#### MEDICAL RECORD

June 13, 1908.

1. The Winning Fight Against Consumption, By JOHN B. HUBER.
  2. The Unfinished Business of General Hospitals, By S. S. GOLDWATER.
  3. Recurrent Vomiting, By HERBERT SWIFT CARTER.
  4. The New School Hygiene, By GEORGE W. VANDERGRIFF.
  5. A Preliminary Note on the Disinfection of Body Cavities by Injection of Suspensions of Living Nonpathogenic Bacteria, By CHARLES E. NORTHE.
4. **The New School Hygiene.**—Vandergriff states that a subdepartment of hygiene in the department of health or education might be established, not only in cities, but in every rural district, under the sole authority of an associate superintendent, who shall be a physician, and have full charge not only of the discovery and correction of physical defects, but of all school matters pertaining to the welfare of school children, embodying questions of properly constructed buildings, of playgrounds, of books, curriculum, home study, and physical training. Under such a régime there will be no division of authority, the single aim being the physical welfare of the school children. Special appropriations should be made by the board of estimate for its furtherance, and this appropriation should be used for no other purpose. The department should not be, as the board of health now is, forced to live from hand to mouth, borrowing in advance to pay for work done in the past. To earn the confidence of the people, to do its work efficiently, this new department should show clearly what the needs of these defective children are, and should place squarely upon the fiscal authorities the responsibility for success or failure in this labor of "new school hygiene."
5. **Preliminary Note on the Disinfection of Body Cavities by Nonpathogenic Bacteria.**—North deducts from the action of the lactic acid bacteria and other nonpathogenic bacteria, from the killing of the boll weevil by another insect, etc., that the judicious administration of properly selected nonpathogenic bacteria as a means of opposing infections has a basis in reason. If the immunity of any body cavity is largely dependent upon the integrity of its garrison of nonpathogenic bacteria, the question arises whether this integrity cannot be maintained and the personnel of the garrison even improved by trained culture strains introduced by the bacteriologist. Metchnikoff and his followers have already made a beginning. They recommend the drinking of milk soured by selected lactic acid bacteria for the purpose of maintaining the immu-

with these bacteria. The spraying of any infected parts with antiseptics is at best only a superficial method of disinfection. In some of the body cavities—the middle ear, the vagina, and the urethra, and in sinuses and abscesses—it may be that the natural antagonisms which exist between nonpathogenic bacteria and pathogenic forms can be of therapeutic use. The suspensions of lactic acid bacteria may prove to be of service in these cavities, especially where putrefactive processes are causing the irritation.

# BRITISH MEDICAL JOURNAL.

May 30, 1908.

1. The Present Condition of Our Knowledge Regarding the Functions of the Suprarenal Capsules (Oliver-Sharpey Lectures, I), By E. A. SCHÄFER.
2. Recent Progress in the Serum Therapy of Plague, By K. B. N. H. CHOKSY.
3. Cats as Plague Preventers, By A. BUCHANAN.
4. Sporadic Kala Azar in Calcutta, with Notes of a Case Treated with Atoxyl, By U. N. BRAHMACHARI.
5. On Measles, By E. WARD.
6. The Use of Serum in Scarlet Fever, By H. CUMPTON.
7. Horsepox Directly Transmitted to Man, By A. F. CAMERON.
8. Primary Pneumococcic Peritonitis, By A. SMITH.

1. **The Suprarenal Capsules.**—Schäfer, in the first of the Oliver-Sharpey lectures, begins by giving the history of the investigation of the suprarenal capsules, and also a brief account of their structure and development. The work of many observers, beginning with Oliver, has shown that the suprarenal capsules, and to a less extent the pituitary body, yield to glycerin and to water and saline solutions, principles which have an extraordinary effect upon the tone of the heart and arteries, transcending that of any known drug. The active principle is a substance of relatively simple constitution: It may be boiled for a short time without deterioration, is dialysable and insoluble in absolute alcohol, and is not destroyed by acids or gastric juice. For this substance the author suggests the name "adrenin" in preference to the proprietary term "adrenalin." Nothing is known as to the substances from which adrenin is formed in the organism, but it has been suggested that one of these may be tyrosin, which undergoes transformation into adrenin under the influence of a ferment in the suprarenal.

2. **Serum Therapy of Plague.**—Choksy's paper is based on the results obtained during the last two and a half years by thirty observers in different parts of India. The main conclusion deduced is that in the Yersin-Roux antiplague serum we possess a useful and efficacious remedy against the plague. The absence of all antitoxic action is responsible for its limited utility. It must, however, be pointed out that a disease like plague, with a mortality of 80.9 per cent., is not likely to yield to serum therapeutics as well as diphtheria has done. The whole secret of the treatment lies in applying the serum very early. Among patients subjected to this treatment within the first few or even twenty-four hours, it is noticed that the whole course of the disease becomes altered, the normal duration of eight or ten days is reduced to four or five, serious complications of the nervous, circulatory, and other systems are averted, the buboes become absorbed, and convalescence is rapid. If the serum is given between twenty-four

and forty-eight hours after the onset of the disease its action is not so well marked and after the expiration of forty-eight hours it does not appear to influence the course of the disease perceptibly. Small as these gains appear, they are not to be despised in a disease so virulent as plague.

3. **Cats and Plague.**—Buchanan is firmly of the belief that the best way to prevent plague is to keep cats. Plague is spread by rats, and without rats there will be no epidemic. Inoculation against the disease in order to prevent its spread is efficient only for a few months; it does not strike at the root of the trouble, and, further, is not an absolute preventive. It causes sore arms, fever, and absence from work, is greatly objected to by the people, and is not favored by tradition or religion. It is very expensive, a large establishment being required, as it is necessary to inoculate every member of every household. The extensive keeping of cats as preventive of the disease is, on the other hand, of permanent efficiency. The root of the trouble is destroyed, and once the number of cats is sufficient and all rats killed, then all risk of plague is abolished. The cost is *nil*, as no establishment is required—one cat protects a household. And finally there is a very strong tradition in favor of keeping cats, the only exception being the Parsees and Bhowani Dhers. Shotgun quarantines and disinfection are useless, and will continue to be so until proper steps are taken to destroy the rats.

4. **Kala Azar.**—Brahmachari defines kala azar as the disease caused by the Leishmann-Donovan bodies. Hindus are more frequently affected by the disease than Mohammedans, the proportion being about four to one. About one third of the cases are under twenty years of age. Most of the cases are chronic when first seen, with a history of illness for several months, and a spleen extending below the ribs. In many the liver is also moderately enlarged. Our knowledge of the early symptoms of the disease is limited. In one class of cases there is a history of intermittent attacks of fever, lasting for some months, and not benefited by quinine. In another class there is a steady enlargement of the spleen, with only a few attacks of fever. In a third there is a history of attacks of low fever, with progressive enlargement of the spleen. In a fourth the history suggests that of one or two attacks of typhoid fever. In a fifth class there is a history of gastrointestinal troubles, with dysenteric or diarrhetic attacks, followed by œdema of the lower extremities, and aguelike attacks of fever. Other symptoms are progressive emaciation, with anæmia, cachexia, œdema, diarrhœa, dysentery, and hæmorrhages from the skin and mucous membranes. (Edema may appear very early or not until the last. There may be fever of the pyæmic type, with two or more remissions in the twenty-four hours. Among the complications may be mentioned pneumonia, pulmonary tuberculosis, cancer oris, delirium or coma, splenalgia due to infarcts in the spleen, hæmorrhoids which may bleed obstinately and profusely, and large abscesses. The prognosis is always grave. Forty per cent. of the author's hospital cases died, the most frequent cause of death being intractable diarrhœa or dysentery. No drug can kill the parasites.

A prolonged and thorough trial was given to atoxyl in one case, the drug being given for almost six months. The patient improved in general health, there were no symptoms of arsenic poisoning, and no local action of the drug; but the parasites were still to be found in the splenic blood in large numbers. A characteristic feature of the disease is the reduction in number of the leucocytes—this leucopenia may be extreme, and in many cases the proportion of white to red corpuscles is less than one to one thousand. Such a count is almost diagnostic of kala azar. In order that atoxyl may do any good in these cases it must be given in very large doses (gr. xv) every seven to ten days by injection, continued for several months. Splenic puncture for diagnosis is a safe procedure if one uses a hypodermatic needle and does not draw more than one or two drops of blood.

2. **Connective Tissue in Cancer.**—Bonney in the third of his Hunterian lectures summarizes the results of his observations on the connective tissue in cancer. The changes in the connective tissue in cancer are identical with those met with in precarcinomatous states. And these precarcinomatous states can be attained by many different routes, starting in inflammatory conditions which histologically are at first quite distinct from each other and which are initially due to entirely different forms of irritant. In short, it is conceivable that the immediate agent of the precarcinomatous states may be identical in them all, although the initial changes in the tissues were due to totally different causes. The carcinoma cell does not act as a specific irritant—indeed, it is probable that it does not act as a tissue excitant at all *per se*. Tumor cells often penetrate beyond the area of tissue cell proliferation, and lie between the tissue elements without exciting any action in them whatsoever. The tissue cell proliferation accompanying a primary carcinoma cannot be regarded as protective, for the following reasons: (a) There is no evidence of any destruction of the active carcinoma by the tissue cells comparable to those seen in break-in bone metastases or in mental tissue implantations. (b) The infiltrative character of the primary tumor is in marked contrast to the circumscription that obtains in permeated lymphatic and in a lesser extent in venous nodules, in both of which latter conditions no tissue

cell proliferation occurs. (c) The tissue cell proliferation results in a rarefaction of the connective tissue in front of the advancing carcinoma cells, in the course of which mechanically resistant structures such as fibrous tissue and elastic fibres become softened and destroyed. On the other hand, while there is no evidence of active destruction of the carcinoma cells by the proliferating tissue cells, neither are there indications of any active destruction of the inflammatory tissue cells by the carcinoma cells. In the older parts of the growth degenerating stroma may be seen, but the epithelial cells are also coincidentally degenerative. Vigor of cancer cells accompanies vigor of tissue cells, and vice versa. The author's final conclusions are: 1. The onset of the ordinary forms of carcinoma is always preceded by a condition characterized by epithelial hypertrophy and certain constant changes in the subepithelial tissue. 2. This precarcinomatous state may be attained through various inflammatory processes, at first quite distinct from one another, but culminating in the same histological picture. 3. The tissue cell proliferation occurring round a primary carcinoma is part of the precarcinomatous process, and materially assists the progress of the growth. 4. There is no histological evidence of a protective reaction on the part of the tissues to the carcinoma cell. 5. Though changes in the adjoining connective tissue bear some very close relation to the cause of epithelial ingrowth, yet, malignancy having been established, the further spread of the tumor is independent of such assistance.

5. **Postural Treatment of Pulmonary Tuberculosis.**—Wise has devised a lying-out chair for patients suffering from pulmonary tuberculosis which they have used with great benefit. This chair consists of two parts—a downward inclined plane, on which the upper part of the body rests, and a lower portion, which supports the knees and feet. In this way a double inclined plane is thus formed, and while the patient gets all the benefit of gravity—drainage of the cavities, etc., in the lung—yet excessive blood pressure in the cerebral vessels is obviated, as the lower extremities of the patient are not raised above the level of the head. In all other previous attempts to invert a patient, congestion of the head has proved a great obstacle to maintaining the position for any length of time. The patient at first uses the inclined plane for only half an hour, three times a day. Later some hours may be spent in this position, either waking or sleeping. In addition to using the force of gravitation for the drainage of corrupt accumulations in the lung, an important modification of the pulmonary circulation is brought about by the forward inclination of the thorax. The apices of the lungs, now in a more dependent situation, have at once a fuller blood supply, and some parts of the pulmonary tissue become relieved from the weight of the heart, which falls forward to be supported by the arms. A decrease in greater accumulation in the dependent tissues of blood which supervenes in the upper and more con-

nervous centres which control the pulmonary vessels, and on the individual rising from the prone position the blood supply to the lungs and other organs will gradually resume its ordinary condition. This go and come of blood surplusage or recurrent hyperæmia is, to the deteriorating apex, what takes place in the normal being under conditions of rest, alternating with healthy plethora caused by vigorous muscular effort. The bactericidal power of the blood circulating actively in a part has been demonstrated, and artificial hyperæmia as a remedial measure has been attempted in various ways. Cases of pulmonary tuberculosis which should not undergo this mode of treatment are those with a tendency to hæmorrhage, those with disease of a pronounced pneumonic type, or with fluid in the pleural cavity.

## LA PRESSE MEDICALE.

May 13, 1908.

1. The Functions of the Liver and of the Spleen in Their Relations to Hæmolytic Icterus, By L. HALLION.
2. Accidents Following the Injection of Quinine, By R. DE GAULEJAC.

### 1. The Functions of the Liver and of the Spleen in Their Relations to Hæmolytic Icterus.

—Hallion asserts that the spleen intervenes more or less in the three varieties of hæmolytic jaundice. In the first variety the hæmolysis is caused by a fault of hæmatopoiesis. The spleen is perhaps one of the organs of hæmatopoiesis and can intervene as such. But it is rather as a destroyer than as a generator of the red blood corpuscles that it appears capable of acting as a cause; an excessive number of destructible red blood corpuscles influence the increase of its work. In another variety of hæmolytic jaundice it is the plasma that destroys the elsewhere normal globules. The spleen receives an excess of hæmoglobin set at liberty, which is stored up and remains in the tissue. There remains the possibility of a third variety in which the spleen is primarily overworked.

2. Accidents Following the Injection of Quinine.—Gaulejac says that the sloughs that follow a very superficial subcutaneous injection can always be avoided if the general condition of the patient is not bad. An abscess almost always follows an intramuscular injection in a patient formerly infected or intoxicated. It follows then that every intramuscular injection of quinine should be given by preference with slowness, in small doses, at a point unaffected by previous treatment, in the gluteal or abdominal regions, and the patient remain quiet and limit as far as possible the number and force of the contractions of the muscles affected during the day following the intervention.

1. The Surgical Treatment of Cancer of the Neck of the Uterus, By FAURÉ.
2. Cardiac Asthenia and its Treatment with Injections of Serum in the Right Dorsal Region, By ALBERT DESCHAMPS.
3. Diabetes Mellitus in Infants, By R. ROMME.

2. Cardiac Asthenia and Its Treatment with Injections of Serum.—Deschamps says that the proper use of injections of serum in minimum dose gives adequate results in the treatment of cardiac asthenia. The injections should be given in the

right dorsal region. This treatment does not exclude the means ordinarily employed of cardiac hygiene or cardiac tonic, but it contributes to the direct stimulation of the pneumogastric and cervical sympathetic nerves and their centres, to sustain the nutrition of the myocardium, and thus to prolong the resistance of the heart, the aim of all therapeutics.

## BERLINER KLINISCHE WOCHENSCHRIFT.

May 11, 1908.

1. Acute Yellow Atrophy of the Liver in Syphilis, By W. FISCHER.
2. Contributions to the Normal Histology of the Cortex of the Suprarenal Capsule, By OSKAR STÖRCK.
3. Some Remarks on Touch Percussion, By WILHELM EBSTEIN.
4. An Atypical Case of Disturbance of Conduction of Stimulation in the Cardiac Muscle, By G. JOACHIM.
5. Contribution to the Pathology of Metabolism in Gout, By W. LAQUEUR.
6. Connection between Diseases of the Nose and of the Nasopharyngeal Space with those of the Eye, By A. ONODI.
7. Concerning the Hæmolysis of the Streptococci, By T. HEYNEMANN.
8. Critical Review of the Action of the Lactobacillus and the Yoghurt Milk, By J. LEVA.
9. Sarcoma of the Prostate (Concluded), By WOLFGANG VEIL.
10. Difficulties in the Diagnosis of Cerebral Tumors, By EDMUND FORSTER.

2. Histology of the Cortex of the Suprarenal Capsule.—Störck says that the overwhelming majority of the so called adenomata of the cortex of the suprarenal capsule have in fact no right to such a designation. The formations of this kind situated at a greater or less distance outside the suprarenal capsule originate in foetal processes of detachment of the cortex, which later in life might be looked upon as hypertrophic new formations of tissue. Similarly there arise foetal and postfoetal formations within the suprarenal capsule, on the inner surface of the cortex and extending beyond its limits. Only circumscribed formations of this kind which present the criterion of continual growth are entitled to the designation adenoma. A distinctive histological diagnosis of the adenoma from the appearance of the cells, perhaps from peculiarities in the size, form, and constitution of the cells and cell bands in contrast to the picture of the physiological paradigm seems to the author scarcely possible.

7. Hæmolysis of Streptococci.—Heynemann alleges that the highly virulent streptococci, such as those productive of puerperal fever, produce on a certain blood agar plate, 5 c.c. agar and 2 c.c. blood, a characteristic clear hæmolytic areola about each colony, and that by this peculiarity virulent streptococci may be distinguished from those which are little if at all pathogenic.

9. Sarcoma of the Prostate.—Veil reports and discusses a case of primary sarcoma of the prostate with metastases in the liver. The sarcoma was spindle-celled and contained also a highly distinctive form of cell, very large, rich in protoplasm, sometimes multinuclear, in the form of long fibres which resembled contractile elements. These cells were not found in the metastases.

## MÜNCHENER MEDIZINISCHE WOCHENSCHRIFT.

May 12, 1908.

1. Concerning Focal Symptoms in Diffuse Diseases of the Brain, By SÄNGER.
2. Advances in the Diagnosis of Tumors of the Brain, By KNAPP.
3. Concerning the Use of Gum Arabic as an Addition to the Anæsthetic in Lumbar Anæsthesia, By ERHARDT.
4. Concerning the Demonstration of Typhobacilli in the Cerebrospinal Fluid in Typhoid Fever, By NIETER.
5. Concerning the Signification of Soapy Stools in Infancy, By HECHT.
6. Concerning the Operative Treatment of Hernia in Children, By GROSSMANN.
7. Concerning the Signification of the Reflex of the Tendo Achillis, By CONZEN.
8. Remarks Concerning the Pathogenic Microorganisms "Chlamydozoa," By PROWAZEK.
9. Experiences with and Studies of Lumière's Three Color Photography, By SIEVERS.
10. Treatment of Fractures of the Forearm, By KÄFER.
11. Treatment of the Decubitus, By TELLER.
12. A Congenital Hairy Pharyngeal Polyp, By LEVINGER.
13. Concerning Gastrosocopy, By LÖNING and STRIEDA.
14. Cataplasma Redivivum, By PAULL.
15. Obituary of Geh. Medizinalrat Dr. Baer, By HOPPE.

1. **Focal Symptoms in Diffuse Diseases of the Brain.**—Sänger states that in multiple sclerosis and progressive paralysis focal symptoms play a great part, as they do also in the obscure cases which have been termed by Nonne pseudotumors of the cerebrum. He reports several cases, among them that of a man, sixty-two years of age, who was suddenly attacked with a right sided hemiparesis and disturbance of speech associated with a bilateral choked disc. Nothing wrong could be found with the brain, either macroscopically or microscopically.

3. **Addition of Gum Arabic in Lumbar Anæsthesia.**—Erhardt recommends the addition of three per cent. gum Arabic to a one per cent. solution of tropacocaine for use in lumbar anæsthesia. He does not consider the combination with other narcotics to be advisable.

4. **Typhobacilli in the Cerebrospinal Fluid in Typhoid Fever.**—Nieter alleges that in certain doubtful cases the diagnosis of typhoid fever may be determined by an examination of the cerebrospinal fluid.

5. **Soapy Stools in Children.**—Hecht says that the fat dyspeptic stools of the artificially and breast fed children contain abundant mucus, while on the contrary the soapy stools contain no mucus, as the mucus prevents the soapy appearance. His conclusions concerning the semeiology of the soapy stools are: 1, A moderate degree of disturbance of the resorption of fat must be present; 2, there can be no hindrance to the subdivision of the fat; 3, much acidity must be absent; 4, peristalsis cannot be greatly accelerated; and, 5, much catarrhal irritation cannot be present.

7. **Reflex of the Tendo Achillis.**—Conzen states that he has examined 3,200 cases, and found the reflex of the tendo Achillis lost or reduced only when something pathological could be demonstrated in the nervous or muscular system. Examination of this reflex should never be omitted, because it is as constant a symptom as the patellar reflex, it reacts at least just as sensitively as the patellar reflex to diseases of the nervous system, and frequent-

ly a difference in the tendon reflex may indicate pathological processes in the nervous system.

12. **Congenital Hairy Pharyngeal Polyp.**—Levinger removed from the pharynx of a child six and a half months old a polyp measuring six by one and a half centimetres, covered with skin and numerous fine hairs.

9. Primary Carcinoma of the Hepatic Ducts. The Report of a Case with the Autopsy, By C. L. SCUDDER.
10. The Operative Treatment of Intractable Vomiting, not due to Pyloric Obstruction. Neurosis of the Stomach, By W. MEYER.
11. The Value of Enterostomy and Conservative Operative Methods in the Surgical Treatment of Acute Intestinal Obstruction, with Remarks on the Importance of Operations in Two Stages, By C. A. ELSBERG.
12. The Nonabsorbable Suture and Ligature, By O. H. ALLIS.
13. Report of Saturday Surgical Clinics for Students held at the German Hospital, Philadelphia, 1906 and 1907, By J. B. DEWEY.

1. **Subtemporal Decompressive Operations for the Intracranial Complications Associated with Bursting Fractures of the Skull.**—Cushing finds the following advantages from this procedure: 1. The approach is made through the thinnest available part of the skull. 2. The opening is made under the temporal muscle. When the split fibres of the muscle are closed there is little tendency to bulging of the brain, or to subsequent obtrusive depression. A subsequent defect in this situation is harmless. 3. With rupture of the meningeal or its branches the extradural clot is brought into view and the vessel can be easily ligated. 4. In bursting fractures, with laceration of the brain, the tips of the temporal and base of the frontal lobes suffer most frequently, and subdural extravasation from this source can be most easily removed through an opening in this situation. 5. Since the lines of fracture in these accidents usually seek the midcranial fossa, bleeding from the base can be easily drained from under the temporal lobes through the temporal

fossa. 6. Subsequent edema of the brain can be best met with by an opening in this situation, under the muscle. 7. In addition to promoting subsidence of acute symptoms, these operations also lessen many of the unpleasant signals, such as traumatic neuroses.

2. **Osteoplastic Resection of the Skull.**—Wood notes the great advantage of this method of entering the skull. The instrument devised by Stellwagen marked a great advance in this department of surgery. Its objections were the fatigue which its use entailed to the forearm muscles, the insecurity of the plate upon which the shaft of the instrument revolved, and the free hæmorrhage from the scalp while the bone was being sawn. These objections have been effectively remedied in the author's instrument, which he has used with satisfaction in a number of instances. He asserts for it the following advantages: 1. It enables one to cut an osteoplastic flap quickly and safely. 2. No injury can be done, even if the instrument is used carelessly or clumsily. 3. Every part can be sterilized by boiling. 4. It is always ready for use, and there are no complicated parts to get out of order. 5. It is complete in itself and does not depend upon electric currents, motors, assistants, or anything, but the operator's hands.

5. **The Treatment of Dislocation of the Shoulder Joint Complicated by Fracture of the Upper Extremity of the Humerus.**—Mason offers the following conclusions: 1. Every dislocation of the shoulder, associated with fracture of the upper extremity of the humerus, is a grave injury, and is likely to result in serious impairment of function, if not promptly treated. 2. Every such injury should be subjected to x ray examination. 3. All manipulative efforts at reduction should be gentle, and should never bruise or lacerate the tissues. 4. Excision should be practised only after failure to reduce with open arthrotomy, or when there is extensive comminution of the upper extremity of the humerus, or when, in fracture of the anatomical neck, it is improbable that the upper fragment will unite with the lower. 5. After reduction, the broken tuberosity should be nailed into position, or should be removed, if necessary. 6. Manipulation failing to produce reduction, immediate arthrotomy, and reduction, with suitable treatment of the fracture, are indicated. 7. Rigid asepsis is essential, and the operations should not be undertaken if asepsis is impossible.

#### AMERICAN JOURNAL OF OBSTETRICS.

MAY 1906.

1. The Crime of Gynæcology. By C. W. BARRETT.
2. Preservation of the Ovaries Entire or in Part in Supravaginal or Panhysterectomy. By R. PETERSON.
3. Rupture of the Uterus through the Cæsarean Cicatrix. By G. L. BRODHEAD.
4. Report of Two Cases. (A) Myxosarcoma of the Round Ligament. (B) Fibroma of the Anterior Abdominal Wall. By W. KRUSEN.
5. The Necessity for the Artificial Feeding of Infants. By L. JOHNSON.
6. Menorrhagia and Metrorrhagia (Uterine Hæmorrhage). By T. KUHO.

1. **The Crime of Gynæcology.**—Barrett's conclusions are the following ones: 1. Charity patients in hospitals do not generally have the privilege of choosing their physicians. 2. They should there-

fore be attended by men trained in the care of their particular diseases. 3. One fourth or more of the charity surgical beds are occupied by gynæcological patients. 4. Many gynæcological diseases are not surgical. 5. Gynecologists are prepared and trained to treat pelvic disease. 6. General surgery has other problems for its proper field. 7. Gynecology should be recognized in order that the pelvic diseases of women be efficiently treated. 8. Gynecology is a special department of knowledge. 9. Its clinical teaching should be in the hands of those who are informed on such matters. 10. The Cook County hospital should have a large gynæcological clinic. 11. Many gynæcological cases require both vaginal and abdominal work. The gynæcologist should have the choice of either. 12. If this is not conceded, inefficiency will be the result. 13. The crime of gynæcology is that it stands in the way of the surgeon's economic interest. 14. The crime of general surgery is that it encroaches upon other specialties. 15. This results in less efficient work. 16. The question should be, what is best for the patient? 17. Reforms are necessary in the direction referred to to obtain the best results.

2. **Preservation of the Ovaries Entire or in Part in Supravaginal or Panhysterectomy.**—Peterson's conclusions are as follows: 1. Ten per cent. of those who are still menstruating at the time the uterus and ovaries are removed will not be troubled by the artificial menopause. 2. This percentage will be more than doubled if a portion of ovarian tissue is retained. 3. Symptoms due to the artificial menopause are not severe when the ovaries are not removed with the uterus. 4. A young woman from whom uterus and ovaries are removed does not necessarily have a troublesome menopause. Those who are operated upon between the ages of forty and forty-four suffer the most. 5. It should not be the rule to remove the ovaries with the uterus in those who have passed forty. 6. The severity of the artificial menopause is by the variety of hysterectomy, whether the ovaries are removed or not. 7. The severity of the artificial menopause is uninfluenced whether the uterus and ovaries are removed for fibroid or inflammatory disease. 8. If a portion of the ovaries is retained after hysterectomy, the period of bad symptoms from the menopause will be shortened. 9. The larger the portion of the ovaries retained, the less severe will the menopause symptoms be.

3. **Rupture of the Uterus Through the Cæsarean Cicatrix.**—Brodhead draws the following conclusions. 1. Rupture of the uterus through the Cæsarean cicatrix is of rare occurrence. 2. With prompt operative methods the mortality is comparatively low. 3. When pregnancy follows Cæsarean section the patient can usually be again delivered with safety by the same method. 4. In repeating a section labor should be anticipated by a week or ten days. 5. If section is to be repeated and labor sets in prior to the time elected for operation, the Cæsarean should be performed as soon as possible after the onset of labor pains. 6. Sterilization may be done at the time of section if the patient so desires. 7. Suture of the laceration has proved successful, but in some instances hysterectomy will be the method of choice.

## THE PRACTITIONER.

May, 1908.

7. The Value of the Opsonic Index in the Treatment of Pulmonary Tuberculosis, By A. C. INMAN.
8. The Treatment of Pulmonary Affections by the Inoculation of Vaccines Controlled by the Opsonic Index, By J. C. BRISCOE and E. U. WILLIAMS.
9. A Surgical View of the Opsonic Method, By H. S. COLLIER.
10. On the Treatment of Skin Diseases by Inoculation after the Opsonic Method, By A. WHITFIELD.
11. The Treatment of Lupus and Tuberculous Disease of the Ear, Nose, and Throat by Inoculation, By H. F. TOD and G. T. WESTERN.
12. Ulcerative Endocarditis and Its Treatment by Vaccine Therapy, By T. J. HORDER.
13. The Tuberculin (T. R.) Treatment of Tuberculosis of the Genitourinary Organs, By J. W. T. WALKER.
14. The Opsonic Method and Vaccine Therapy in Relation to Diseases of the Eye, By R. W. ALLEN.

2. **Some Observations on the Opsonic Index.**—Fleming summarizes his paper as follows. 1. The variation in the tuberculoopsonic index of healthy individuals is very small, normal serum furnishing a good standard for the comparison of infected persons from day to day. 2. With a diminution of the number of washed corpuscles in the opsonic mixture there is an increase in the amount of phagocytosis. 3. Agglutination of the washed red corpuscles increases the amount of phagocytosis. 4. The tuberculoopsonic index is the same whether washed corpuscles are used from a healthy or tuberculous individual. 5. If red corpuscles are taken up with serum, the amount of phagocytosis is reduced. 6. Serum sealed in a capsule at room temperature retains its full power in healthy blood for a week, and in pathological blood for a day or two less. 7. Blood capsules left open for several hours give untrustworthy readings. 8. Two practised observers counting the same slides can obtain results varying not more than ten per cent. 9. Duplicate estimations of the tuberculoopsonic index of tuberculous patients can be performed, the results rarely differing from each other by less than twenty per cent.

3. **Opsonic Index in Infants.**—Wells draws the following conclusions: 1. A low opsonic index is not diagnostic in children under one year of age. 2. In infants a low opsonic index is not inconsistent with health, and a child may be thriving well with a declining index. 3. Where the opsonic index is low, it will rise in response to the stimulus of an inoculation with bacterial vaccine. 4. Inspection of the results tabulated by the author seems to show that the healthy breast fed infant possesses no advantages over the healthy artificially fed child. 5. The author feels definite in children cannot depend on the opsonic content of the serum.

4. The Experimental Error in the Method of Determining the Tuberculoopsonic Index of the Blood.—White refers to recent attempts to impugn the accuracy of the method of determining the opsonic index of the blood. Of course, no method is free from error, and the error must vary with the worker. This is especially true in a complicated process like this, in which every step is a possible pitfall. If one has imperfectly mastered the details of the procedure the error in determining the opsonic index may be very great. When these details are mastered the experimental error will be insignificant. The author gives a table in which the variations between the counts of the different normals employed on the same day and incubated with different batches are only from four to eight per cent. With increased experience the author believes that this error can be still further lowered.

5. **Statistical Considerations Relative to the Opsonic Index.**—Greenwood thinks that in the present state of the question we can say: 1. There is no valid evidence that the limits of error do not exceed twenty per cent. of the mean value. 2. The skewness of the distributions thus far examined is so great that, in the case of low emulsions, errors in excess are more frequent than errors in defect of the mean. 3. There is reason to hope that with high emulsions the variation may become more symmetrical. The practical suggestions are that (a) high indices should be more carefully scrutinized than low values; (b) that it is better to work with rather thick emulsion, giving an average for the normal serum of not less than three bacilli per cell.

7. **The Value of the Opsonic Index in the Treatment of Pulmonary Tuberculosis.**—Inman finds that: 1. Early or febrile cases of pulmonary tuberculosis may be treated with advantage by means of pure air and graduated exercise. If such treatment is used it must be remembered that tuberculin by autoinoculation is being employed. 2. The opsonic index is a valuable guide to such treatment and also gives useful information if inoculations of Koch's tuberculin are employed. 3. Rest is essential in febrile cases of consumption, and in these cases injections of tuberculin, using as a guide the opsonic index, is the proper treatment. The latest methods of treating consumption are those which cooperate with the natural methods employed by the body itself for its own protection and defense. Both in febrile and afebrile cases a watch is kept over the blood by the opsonic index.

9. **A Surgical View of the Opsonic Method.**—Collier states that he was formerly opposed to this method for diagnostic and prognostic purposes, but that he was converted by several cases in which the opsonic method was successful as compared with methods previously in use. It must be remembered that with opsonins, if such substances really exist, there is no such accuracy of treatment as is obtained by chemistry. In eleven specimens of blood from a patient with influenza, the white cells were sent to ten laboratories, the results varied between 84 and 114. A case of myeloid leukaemia with this result is not far from the truth in the present organism. A case like a few in a group of leukæmic tumours, in which the white cells

cases. If an operation is contemplated, a period of low opsonic index will usually offer the best results. The author recommends that surgeons be clinically associated with opsonists.

#### ARCHIVES OF PÆDIATRICS

May, 1908.

By SARA WELT KAKELS.
7. Hydrotherapy in Childhood.  
By F. GROSSE.
8. The Use of Analgesics in Pædiatric Practice.  
By LE GRAND KERR.

2, 3. **Kidney Lesions in the Infant.**—*Pathological Aspects.* Thompson states that literature on the infant kidney is scanty. Pathologically kidney lesions may be acute or chronic; they may also be degenerative, exudative, or proliferative. The author analyzes the kidney conditions in fifty autopsies upon infants as follows: In one case there was congenital narrowing of the ureter at its vesical insertion. In one case there was abnormal hyperplasia of the pyramidal portion of a foetal lobe in one kidney. Uric acid infarcts were frequent in those who had died within three weeks from birth. Three calculi were found in the pelvis of one kidney, composed of acid urate of ammonium. Small cysts connected with the tubules and glomeruli were found in five cases. Congestion was frequently observed in the capillaries between the convoluted tubules, the glomeruli and their interspaces being filled with blood. Thrombi of fibrin were found in the junctional veins. Severe exudative and proliferative lesions were not found, but degenerative changes resulting in albumin and casts were frequent. Microscopically there were frequent examples of cloudy swelling of the tubular epithelium. In many of the glomerular tufts there was an increase in cells, but not so as to constitute glomerular nephritis. The conclusion is that marked disturbances of circulation and slight or moderate degenerative processes are very common in the infant kidney. *Clinical Aspects.* Brady quotes Baginsky as to the importance of kidney lesions in infants in diarrhoea. The convulsions which so often end such cases are frequently uræmic. Morse thinks true nephritis a rare complication of dysentery, but that degenerative changes of the epithelium due to bacteria and their toxins are not infrequent. Vaccinia, pneumonia, and malaria are mentioned as forerunners of nephritis. Nephritis is often complicated with congenital syphilis, again it may be excited by potassium chlorate, salicylic acid, and carbolic acid, and the irritating action of metabolic products may cause it in connection with marasmus and rickets. With albuminuria, which is almost constantly present in infants, are often found hyaline and epithelial casts. Hæmaturia may be present as the result of scorbutus, purpura, uric acid infarcts and calculi, pyelitis, tumors of the kidney, and acute

nephritis. Holt states that acute nephritis in infants is not so rare as might be supposed. Neither casts and albumin nor œdema and anasarca are necessarily evidences of nephritis in infants. The disease usually tends to complete recovery.

### Proceedings of Societies.

#### THE ASSOCIATION OF AMERICAN PHYSICIANS.

*Twenty-third Annual Meeting, Held in Washington, May 12 and 13, 1908.*

The President, Dr. JAMES TYSON, of Philadelphia, in the Chair.

(Concluded from page 1126.)

**Cases of Relapsing Fever, with Demonstrations of the Spirochætæ in the Blood of Patients and of Inoculated Rats.**—Dr. JOHN W. HUNTER and Dr. THOMAS A. COPE, of Philadelphia, reported two cases of relapsing fever. Both patients were natives of Turkey; the first patient had arrived in Philadelphia from France and had slept with the second patient; on three of the nights he had had fever. Ten days after the patient was exposed to infection from the first patient he was admitted to the hospital. In one of the patients the leucocyte count was normal; in the other there was a leucocytosis of 15,000. The authors believed that the spirochætæ belonged to the bacteria. They had not succeeded in demonstrating cilia on them, or in cultivating them except for a short time in rats, where a few organisms were seen; they had been unable to inaugurate bedbug experiments. The organisms disappeared from the peripheral blood in both cases when the crisis occurred.

**The Action of Purgatin on the Kidneys.**—Dr. FRANZ PFAFF, of Boston, said that purgatin had been alleged to be the best of all the organic purgative compounds synthetically prepared. It was said that it did not produce griping, and, although excreted by the urine, that it did not cause renal irritation. Pfaff had studied the action of purgatin on dogs, cats, rabbits, and guinea pigs. Dogs and cats were not affected by it; rabbits and guinea pigs, on the other hand, were affected by the drug. The intestines and the other internal organs were discolored at autopsy, after the animals had lost weight and died of exhaustion. In nine out of ten rabbits there was marked acute nephritis. In dogs there was no acute nephritis. The experiments showed that purgatin did cause acute Bright's disease and death in certain animals. It might cause irritation of the kidneys in certain human beings and ought not to be used in therapeutics.

#### THERAPEUTICS.

**The Therapeutics of Self Repair.**—Dr. S. J. MELTZER, of New York, said that millions of men have meddled with the phenomena of life for hundreds of years without the proper knowledge of the organism or its physiology; but no serious results had followed, because of the power of the organism to recover from its own disorders. The power of automatic repair was not even now thoroughly appreciated. Therapeutics was the most important part of

medicine, and contempt for treatment was an anomaly. It was the duty of the physician to discover artificial remedies; not to depend entirely upon the fact that self repair was possible. Therapeutics might be divided into, first, rational therapeutics, which was inactive; and, second, empirical therapeutics, which was active but unreliable. The attempt to produce immunity was the most rational of the therapeutic procedures. The signs of inflammation were considered as attempts at self repair, and all these signs were employed in therapeutics as aids in the correction of inflammatory conditions—for example, Bier's method of artificial hyperæmia, the artificial production of leucocytosis, the artificial production of fever, and the artificial injection of sterile pus. The methods followed by Nature for the repair of injuries to the organism should not be followed strictly by the therapist, however, but they should be improved upon if possible. We should not make the patient uncomfortable for mere theories, but we should attempt to make life bearable as well as to save life. The phenomena of disease should be treated even if they belonged to the phenomena of self repair, provided they made the patient miserable. The fact of continuous recoveries was an argument in favor of rational therapeutics, both physiological and pathological.

**Dietetic and Hygienic Therapeutics.**—Dr. DAVID L. EDSALL, of Philadelphia, said that there was a growing tendency to condemn drug treatment and to laud hygiene and diet as therapeutic measures. The majority of young men, however, got better results from drugs than from diet and hygiene, because they used drugs more rationally. This was due to the point of view of the student, who was instructed systematically in drug therapeutics, but not in the rationale of hygiene and diet. The student overlooked the importance of the commonplace, particularly the things that occurred in relation to occupation. He was unable to correlate his scientific and practical knowledge. In dietetics the great fault was that of treating the name of the disease rather than the disturbance of function, and foods were often used without a knowledge of their nutritive value.

**Organotherapeutics.**—Dr. REID HUNT, of Washington, said that organotherapy was the utilization of the internal secretions. The present tendency was to study the rôle of the hormones in the body, to attempt to obtain them in a suitable form for therapeutic purposes, and to try to influence them as they occurred in the body. The secretion of the suprarenal body was the typical example of a hormone. There had not recently been much advance in thyroid therapy, but the discovery of the independent function of the parathyroids was of great importance. The recognition of the uses of a liquid waste product, such as carbon dioxide, the rôle of the internal secretion of the organs of reproduction; and the discovery that embryos produced an internal secretion which appeared to exercise a restraining influence on malignant growths were of great importance. The substances offered for therapeutic purposes were about the same as they had been one hundred years ago, and they were advertised in much the same language as was used a century ago. Many hormones might in the future be made synthetically, and the synthetic product would probably

be better than the natural hormone. The only function of certain organs was to produce hormones; in other cases the organ also destroyed poisons. As an example of the possibility of influencing the production of hormones in the body the author referred to the effect of hydrochloric acid on the mucous membrane of the duodenum, the influence of the x rays on the internal secretion of the ovary, and the influence of iodine on the secretion of the thyroid body. The activity of extracts of the thyroid body depended upon the iodine contained in them. Investigations conducted by the author had shown that "protonuclein" was, to all intents and purposes, desiccated thyroids, and so unsafe.

**Serum Therapeutics, Including Treatment with Specific Vaccines.**—Dr. MARK W. RICHARDSON, of Boston, reviewed the results with the various sera that were in common use at the present time. He spoke of the use of fresh normal serum in doses of fifteen to twenty cubic centimetres in the treatment of hæmorrhage and of the hæmorrhagic diathesis. He referred to the serum treatment of actinomycosis, anthrax, carcinoma, cerebrospinal meningitis, cholera, colon infections, diphtheria, bacillary dysentery, erysipelas, gonorrhœa, plague, pneumonia, sarcoma, snake poisoning, tuberculosis, etc. He spoke of the treatment of cerebrospinal meningitis, colon infections, gonorrhœa, staphylococcus and streptococcus infections, tetanus, and tuberculosis with bacterial vaccines. In Dr. Richardson's own service, in Boston, the treatment of 132 cases of typhoid fever with typhoid products had reduced the relapses from twenty to five per cent. He thought that the determination of the opsonic index was unreliable as a guide to the administration of bacterial vaccines.

**Psychotherapeutics.**—Dr. LEWELLYS F. BARKER, of Baltimore, read a paper on this phase of the therapeutic art. He reviewed the psychotherapeutic methods, both the conscious and the unconscious ones, practised in the past, as well as those practised at the present time. He described those methods that were used in a legitimate way as well as those that were used illegitimately. He said that psychotherapy was also physical therapy, and probably psychophysical therapeutics would be a better name for the collection of methods which made up the subdivision of therapeutics under consideration. Mesmerism, hypnotism, isolation, suggestion, persuasion, and inspiration of authority all belonged to the class of measures referred to. The use of psychotherapeutic means should always be preceded by an accurate diagnosis.

**The Radical Cure of Constipation by Psychotherapy.**—Dr. IRVING P. LYON, of Buffalo, described his method of treating chronic constipation. He considered the disorder to be, generally, a simple psychoneurosis which altered or obstructed the normal innervation of the intestine. The faulty nerve control was further intensified by dependence upon cathartics, so that there were two bad habits to correct instead of one. Drugs, he regarded as unnecessary in the treatment of the disorder if not positively harmful, and the attention of the physician should be given to instructing the patient how to get himself into the habit of having a regular stool daily. Dr. Lyon reported sixty-seven cures out of sixty-nine attempts.

**Physical Therapeutics.**—Dr. R. TAIT MCKENZIE, of Philadelphia, said that exercise as a therapeutic agent should include all means by which the body might be acted upon by movements, active or passive, with or without the aid of apparatus. Active exercise included games which preserved and cultivated the old coordinations of throwing, catching, striking, climbing, running, and leaping necessary for complete development of the individual, difficult to get naturally under city conditions. This form of exercise might be subdivided into exercises of effort and exercises of endurance. Exercises of effort were contraindicated in cases of arteriosclerosis, advancing age, valvular heart lesions, and active tuberculosis of the lungs. Exercises of endurance were contraindicated in cases of anemia or cachexia from any cause. In sound young men exercises combining both effort and endurance were productive of no evil after effects. In duplicate movements the direction of the movement was controlled and the resistance was prescribed; in other words, the dose was measured. The advantages of this method were its accuracy, the possibility of specializing on isolated muscle groups, and the possibility of stretching contracted parts beyond what was possible by the voluntary power of the patients. In passive movements no will power was required, and the action on muscular nutrition was mechanical. These movements, as was well known, came under the heads of massage and mechanotherapy. The speaker then took up the various diseases in which the different methods of exercise were applicable. In conclusion, he said that exercise in its application to pathological conditions of posture, circulation, nutrition, and the nervous system must depend for success on accuracy of dose, persistence in following out the treatment prescribed, and the careful observation of the patient by a competent observer during the course of the treatment.

Dr. HOBART A. HARE, of Philadelphia, said that there was a wide breach between experimental pharmacology and bedside experience, and that the greater success of the older man depended upon this experience. The ability of the body to adjust itself to the onslaught of disease and the active medication of disease could but be apparent to any one who was at all observant. The accepted pharmacological action of a drug might not be its true physiological action. Some drugs must influence the metabolic processes. The administration of antitoxines and bacterial vaccines converted the patient into a battlefield between the invading organisms and the antitoxines, and they should be used with great care. The adoption of psychotherapeutic measures should not lead to the exclusion of other satisfactory methods. He would urge that, in addition to the encouragement of research to produce new drugs, we should not give up methods of treatment which had been uniformly successful in the hands of our forefathers.

Dr. M. J. ROSENAU, of Washington, said that the administration of ether, referred to by Dr. Meltzer, did not save life when life was imperiled by the phenomenon of anaphylaxis.

**The Clinical Value of the Tests of von Pirquet and Calmette, Based upon Personal Observation.**—Dr. CHARLES L. GREENE and Dr. FRANK E. BURCH, of St. Paul, gave an account of the prac-

tical utility of the cutaneous and ophthalmic tuberculin tests, based upon their experience in eighty-three cases. The patients were all over eight years of age. The authors concluded that the reactions were comparable to that of the old injection test with tuberculin; that the two tests ran parallel; that both tests were active, but that the subcutaneous test was the more reliable; that all patients with tuberculosis reacted; that the late reaction was more common in cases of arrested tuberculosis; that advanced cases with a low resisting power gave a slight reaction; that a failure to react was of great clinical value; that the tests were of genuine clinical service; that the reported bad results following the ophthalmic test indicated the necessity for caution in its application; and that relatively few persons reacted who did not show tuberculosis on careful examination.

**A Comparison of the von Pirquet, Calmette, and Moro Tuberculin Tests and their Diagnostic Value.**—Dr. SAMUEL MCC. HAMILL, Dr. HOWARD CHILDS CARPENTER, and Dr. THOMAS A. COPE, of Philadelphia, reported the results obtained in 134 cases in children under complete control, in one of the orphan asylums in Philadelphia. The tuberculin was prepared in one laboratory, by a uniform method, the doses were uniform, and all the patients were subjected to a careful physical examination after the tests were made. All the patients were under eight years of age. They had found uniformity of reaction with all three methods. The conjunctival test was sometimes followed by serious inflammations of the eye with subsequent loss of vision. The cutaneous and the ointment tests were both better than the ophthalmic test. The ointment test offered the further advantage that it did not furnish a portal of entry for secondary infections through abraded surfaces. They considered that all these methods were of less value than it had been hoped they would be for the diagnosis of the irregular forms of tuberculosis; that a negative reaction was of more value than a positive one; and that the type of the reaction bore no relation to the type of the disease.

**The Ophthalmotuberculin Reaction; A Warning.**—Dr. M. J. ROSENAU and Dr. JOHN F. ANDERSON, of Washington, said that the normal conjunctiva might be sensitized by the instillation of tuberculin. After fifty-one days a second instillation in one case was followed by a rapid and severe reaction. Such a reaction had no clinical significance, because a tissue which responded to ordinary irritants so quickly as the conjunctiva would concentrate the immunizing forces upon the spot at which the material was applied.

Dr. W. P. NORTHRUP, of New York, said that he considered the ophthalmotuberculin reaction dangerous, but believed that the cutaneous test was reliable.

Dr. HAMILL said that in his tests he had used three points of inoculation; one for the Moro test, one for the von Pirquet test, and the third for salt solution as a control.

Dr. W. R. BALDWIN, of Saranac Lake, N. Y., said that the amount of tuberculin used in the test should be as small as possible, so as to prevent the

reaction of nontuberculous patients. The tests did not appear to offer any prognostic aid.

**Tronchin. A Sketch of His Life.**—Dr. F. C. SHATTUCK, of Boston, read a sketch of Tronchin, whom he described as a great practitioner, who never wrote a book, and who was, consequently, almost unknown.

**Fatigue in School Children as Tested by the Ergograph.**—Dr. R. G. FREEMAN, of New York, said that the theory as usually stated was that school children possessed a power for increased work from morning till noon, that the working power lessened during the noon hour, and that it was lowest when the children left school in the afternoon. In children whom he had tested in the New York public schools, he had not found evidences of fatigue with the ergograph. He said that the Crampton test was of no value and neither was the Storey ergograph in testing for fatigue in school children. He thought that an ergograph might be of some value in "trying out" children so that the day might be modified for those who did show fatigue.

**Ascitic Exudate in Typhoid Fever.**—Dr. ALEXANDER MCPHEDRAN, of Toronto, reported six cases of typhoid fever in which ascites occurred without demonstrable peritonitis. All the patients recovered.

**Further Observations on the Pleural Reflexes.**—Dr. JOSEPH A. CAPPS and Dr. D. D. LEWIS, of Chicago, described further experiments on the influence of mechanical and chemical irritants on the blood pressure of dogs when they were applied to the pleuræ. In a series of dogs with normal pleuræ and in a second series with artificially induced pleurises, the pleural cavities were washed out with various solutions. Fifty cubic centimetres of fluid were used in each case. If this solution was very irritating, it was subsequently washed out with sterile water. Hot water alone was used in eight cases of normal pleuræ, with no fall in the blood pressure, and in five cases of empyema, with no fall; cold water was used in four normal pleuræ, with one fall of pressure, and in four cases of pleurisy, with two falls; formalin and glycerin were used in eleven normal pleuræ, with four falls, and in eleven cases of pleurisy, with six falls; a one per cent. solution of iodine (Lugol's solution) was used in six normal pleuræ, with one fall, and in nine cases of pleurisy, with two falls; hydrogen peroxide was used in nine cases of normal pleuræ, with one fall, and in eleven cases of pleurisy, with six falls. The pleura seemed to be supplied with nerves that communicated with the depressor nerves of the heart. In cases of pleurisy the action of these nerves was increased, so that it was not altogether safe to use these solutions on the human subjects.

Dr. F. C. SHATTUCK, of Boston, asked if the authors had used a solution of chlorinated soda in their experiments, a solution used by some surgeons for irrigating the pleural cavity in cases of empyema.

Dr. S. J. MERRILL, of New York, said that it was an interesting fact that the nerve fibres distributed to a surface covered with fibrin had a more pronounced action than the fibres distributed to a normal pleura.

Dr. CARRIE said that in some of their experiments there had been a rise of blood pressure, but the important point in their studies was the decrease in

of the fact that in some cases the blood pressure did fall. It was in these cases that there was danger.

**Acute Pancreatitis.**—Dr. JOSEPH SAILER, of Philadelphia, described some experiments that he had conducted, in conjunction with Dr. C. B. FARR and Dr. JOHN SPEESE, in order to produce pancreatitis. He suggested that in acute pancreatitis certain ferments might escape from the pancreas and exert their fat splitting function on the neighboring tissues. The method of the production of this result was not understood. Almost any foreign substance injected into the duct of Wirsung, with ligation of the duct, would produce it, and, in some cases, ligation of the duct alone was followed by it. In a case of acute pancreatitis, produced by the injection of oil and the ligation of the duct, which was followed by death in twelve hours, the necrotic pancreas was emulsified and injected into guinea pigs. Four of these animals died, but there were no toxic effects. Dogs were injected with this emulsified pancreas, and when they were moribund they were bled and their blood serum was injected into guinea pigs. The guinea pigs died. There was no evidence of bacterial infection. The necrosis of the pancreas was most marked near the bloodvessels. Normal blood serum did not produce the same results. It appeared that a partial immunization could be produced after two or three injections of small amounts of the dog serum. The serum of the dogs injected with emulsified pancreas was more toxic than the serum of normal dogs. The lesions produced were not like any others described.

**Some Clinical Features of Pancreatitis.**—Dr. JOHN H. MESSER, of Philadelphia, described the clinical findings in nine cases of acute pancreatitis. Trauma was an ætiological factor in one, gallbladder disease in eight. There was epigastric tumor in seven, diarrhoea in six, acute anæmia in five, leucocytosis in the six cases in which a blood count was made, shock in six, dyspnoea in eight, and a rapid pulse in all. Cammidge's test was positive in the last four cases.

Dr. REGINALD FITZ, of Boston, said that not much had been added to the methods of diagnosis in cases of pancreatitis in recent years. The work of Dr. Sailer was suggestive because the injection of animals with the serum of a suspected patient might be developed into a diagnostic method.

Dr. WILLIAM H. WELCH, of Baltimore, asked whether Dr. Sailer had tested the toxic action of the serum of his dogs on other dogs. Dog serum was normally toxic for guinea pigs, and it was possible that the results obtained by Dr. Sailer might be those of any alien serum. He would be inclined to doubt the diagnostic value of injection of human serum into animals in suspected cases.

Dr. S. J. MERRILL, of New York, referred to the report of the autopsy on Professor von Bergmann, which seemed to point to acute pancreatitis as the cause of von Bergmann's death.

**Hypernephroma with Metastasis to the Sternum Simulating Aneurysm of the Aorta.**—Dr. ARTHUR A. LINDEN, of Philadelphia, reported the case of a woman aged sixty years, who died of anæmia, and in whom a diagnosis of hypernephroma, accompanied by metastasis to the sternum, had been made. There was a possibility that the tumor of the sternum was the

sternum, in the line of the aorta, which gave a systolic murmur on auscultation. After death this tumor was found to involve the sternum and ribs and was seen to be a metastatic growth secondary to a hypernephroma. There were other secondary growths in the lungs, the uterus, and the liver.

Dr. CHARLES G. STOCKTON, of Buffalo, referred to a case of hypernephroma in which there was intermittent fever. The symptoms of hypernephroma were not unlike those of other malignant tumors.

**The Importance of the Consideration of Negative Results in Blood Cultures.**—Dr. E. LIBMAN, of New York, described the results of systematic blood cultures in 1,500 cases of fever made in the Mount Sinai Hospital in New York. In cases in which the blood culture was negative the disease might be due to an organism not easily cultivated; the organism might not be present in the blood when the culture was made; the organism might not be demonstrable; or the organism might have disappeared from the circulation after the local lesion had been operated upon. In local infections of various kinds, when the local lesion was out of the general blood current, there might be no bacteriæmia. In cases of suspected typhoid fever a negative culture should lead to the suspicion of another disease. A negative blood culture was valuable in the diagnosis of acute articular rheumatism. In a case of local infection with severe constitutional disturbance a negative blood culture indicated that there was no general infection. There was a general infection only when bacteria were found in the blood. A negative blood culture excluded acute ulcerative endocarditis. In chronic endocarditis with fever a negative blood culture was of value in excluding a fresh infection. A negative culture was of value in the diagnosis of infective thrombosis of the veins.

Dr. WILLIAM H. WELCH, of Baltimore, said that when bacteria were found in the blood in the human subject their significance was not the same as when they were found in the blood of the lower animals suffering from septicæmia. In the latter instance the organisms were actually multiplying in the blood stream. In human pathology, on the other hand, the organisms were usually swept into the blood current and were not actively multiplying there.

Dr. LIBMAN said that he had reached the conclusion from his studies that bacteria were found in the blood only when the original focus of the infection ruptured into the blood stream. The organisms were found in the blood all the time in cases of acute ulcerative endocarditis.

**Obstruction of the Superior Vena Cava in Graves's Disease.**—Dr. CHARLES G. STOCKTON and Dr. ALBERT E. WOHNERT, of Buffalo, reported the case (to be published).

Dr. WILLIAM H. WELCH, of Baltimore, asked whether the patient had shown tricuspid regurgitation.

Dr. ABRAHAM JACOBI, of New York, asked whether the enlarged thyroid body had interfered with the venous circulation.

Dr. STOCKTON said that there had been no tricuspid lesion found at the autopsy. The thyroid apparently did not obstruct the veins. The process was not, strictly speaking, a terminal one.

**The Relation of Anaphylaxis to the Toxæmia of Pregnancy.**—Dr. M. J. ROSENAU, of Washing-

ton, said that in his experiments on the phenomenon of anaphylaxis he had found that the guinea pig could not be sensitized with the blood of foetal guinea pigs. The placental juice of the guinea pig, however, when injected into the mother, would sensitize the animal to the placental juice. In man it might be that the toxæmia of pregnancy was due to poisoning with placental cells.

Dr. VICTOR C. VAUGHAN, of Ann Arbor, Mich., said that he had been struck with the resemblance between anaphylaxis and eclampsia.

Eight other papers were read by title.

The following active members were elected: Dr. E. R. Baldwin, of Saranac Lake, N. Y.; Dr. J. A. Capps, of Chicago; Dr. Theodore C. Janeway, of New York; Dr. L. A. Conner, of New York; Dr. R. G. Freeman, of New York; Dr. J. Dutton Steele, of Philadelphia; Dr. Joseph Sailer, of Philadelphia; Dr. H. C. Moffitt, of San Francisco, and Dr. W. F. Hamilton, of Montreal.

The following associate members were elected: Dr. Harlow Brooks, of New York; Dr. J. Alison Scott, of Philadelphia; Dr. W. T. Longcope, of Philadelphia; Dr. J. C. DaCosta, of Philadelphia; Dr. Rufus I. Cole, of Baltimore; Dr. T. A. Claytor, of Washington; Dr. L. Brown, of Saranac Lake, N. Y.; Dr. Victor C. Vaughan, Jr., of Detroit; Dr. J. T. Halsey, of New Orleans, and Dr. C. H. Bunting, of Madison, Wis.

The following officers were elected for the coming year: President, Dr. Victor C. Vaughan, of Ann Arbor, Mich.; vice-president, Dr. Henry Hun, of Albany; secretary, Dr. George M. Kober, of Washington; recorder, Dr. S. Solis-Cohen, of Philadelphia; treasurer, Dr. J. P. Crozer Griffith, of Philadelphia; councillor, Dr. S. J. Meltzer, of New York; representative on the executive committee of the Congress of American Physicians and Surgeons, Dr. F. H. Williams, of Boston (alternate, Dr. W. S. Thayer, of Baltimore).

### Book Notices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

*The Principles and Practice of Hydrotherapy.* A Guide to the Application of Water in Disease. For Students and Practitioners of Medicine. By SIMON BARUCH, M. D., Professor of Hydrotherapy in Columbia University (College of Physicians and Surgeons), New York, etc. Third Edition, Revised and Enlarged. With Numerous Illustrations. New York: William Wood & Co., 1908. Pp. 544.

Scientific hydrotherapeutics has rapidly come to the foreground during the last twenty-five years, and its representative in America is Dr. Simon Baruch, of New York. A book on hydrotherapy from his pen is therefore a well authenticated report on this branch of therapeutics, which is now represented by a department of the Vanderbilt Clinic of the College of Physicians and Surgeons, Columbia University, probably the first school of medicine in America to make hydrotherapy an obligatory study in its curriculum.

Although the book before us is the third edition, we deem it proper to review it at some length, as we have not done so before.

It is divided into two parts, the first part treating, in ninety-five pages, of the physical properties of water and its mode of action in health. The second part deals, in 422 pages, with the practice of hydrotherapy. It contains descriptions and rules of applying water in disease, and then goes into fuller detail as to treatment of diseases, giving the reason for each procedure and its therapeutic indications, with reports of cases. We thus find that Baruch discusses water in the treatment of typhoid fever, measles, scarlatina, pneumonia, enterocolitis, Asiatic cholera, sunstroke, anæmia and chlorosis, phthisis, diabetes, malarial diseases, neurasthenia, neuralgia, hysteria, rheumatism and gout, dyspepsia, and insanity. A full chapter is devoted to hydropic prescriptions. The last chapter of the book gives an historical sketch of hydrotherapeutics. The book may well be recommended to every practitioner.

*The Sexual Question.* A Scientific, Psychological, Hygienic, and Sociological Study for the Cultured Classes. By AUGUST FOREL, M. D., Ph. D., LL. D., Formerly Professor of Psychiatry at and Director of the Insane Asylum in Zurich (Switzerland). English Adaptation by C. F. MARSHALL, M. D., F. R. C. S., Late Assistant Surgeon to the Hospital for Diseases of the Skin, London. Illustrated. New York: Rebman Company, 1908. Pp. 536.

Dr. Marshall has produced a very valuable translation of Forel's *Question sexuelle*, which we reviewed in our issue of July 6, 1907, page 46. The translator as well as the publishers is to be congratulated on having made, through this English version, the French work accessible to a much wider circle of readers. The book is such that, although we may not agree to all of Forel's conclusions, it should be read by every one interested in not only the scientific but also the sociological side of the sexual question.

*The Operations of General Practice.* By EDRED M. CORNER, M. A., M. C., M. B. (Cantab.), B. Sc. (London), F. R. C. S. (England), Surgeon in Charge of Out Patients at St. Thomas's Hospital and to the Children's Hospital, etc., and H. IRVING PINCHES, M. A., M. B., B. C. (Cantab.), M. R. C. S., L. R. C. P. (London), Clinical Assistant to the Children's Hospital, etc. London: Henry Frowde (Oxford University Press) and Hodder & Stoughton, 1907. Pp. xii-206. (Price, £5.50.)

The authors have presented in this volume an excellent manual of the minor surgery that the general practitioner is called on to perform and that he is too frequently unfamiliar with, because it was so insignificant that it was not brought into his surgical course when he was in college. The operations are described under the several anatomical regions, and the book will serve a very practical purpose.

Miscellany.

**How to Enter the Naval Medical Corps.**—We quote the following from the official circular for the information of persons desiring to enter the Medical Corps of the United States Navy:

A candidate for appointment in the Medical Corps of the navy must be a citizen of the United States, between twenty-one and thirty years of age, and must apply to the Honorable Secretary of the Navy for permission to appear

before a naval medical examining board. The application must be in the *handwriting of the applicant*, stating age and place of birth; also the place and State of which he is a permanent resident, and must be accompanied by letters or certificates from two or more persons of repute, testifying from personal knowledge to his good habits and moral character, and that he is a citizen of the United States.

## FORM OF APPLICATION.

(This form is not to be filled in here, but copied on a separate sheet.)

SIR—I request permission to be examined for an appointment as assistant surgeon in the United States Navy.

I was born at....., and was..... years of age on the..... day of....., 190 , and am a citizen of the United States, residing in..... county of..... in the State of.....

I inclose herewith certificates as to moral character, habits, and citizenship.

Very respectfully,

The Honorable Secretary of the Navy,  
Navy Department, Washington, D. C.

If, in reply, the candidate receives a permit, he will notify the president of the naval medical examining board at the U. S. Naval Medical School, Washington, D. C., or at the U. S. Naval Hospital, Mare Island, Cal., the only places where the examinations are held, stating approximately the time at which he desires to be examined and requesting that a date be fixed for his examination.

## THE EXAMINATION

When a candidate presents himself for examination on the date fixed by the president of the board, he must bring with him testimonials as to character and professional fitness, diplomas, and a certificate that he is a citizen of the United States. While it is not essential, it is desirable that candidates should have had hospital experience or at least a year's practice in their profession. The examination usually occupies about nine days, and is conducted in the following order: I.—Physical. II.—Professional. III.—Collateral.

### I.—PHYSICAL EXAMINATION.

The physical examination is thorough, and the candidate is required to certify, on oath, that he is free from all mental, physical, and constitutional defects. Acuteness of vision, 12/20 for each eye, unaided by glasses, but capable of correction by each eye of lenses to 20/20, is obligatory. Color perception must be normal and the teeth good. If the candidate is found to be physically disqualified his examination is concluded; if found to be physically qualified his examination is continued as follows: (1) Letter to the board describing in detail his general and professional education.

## II—PROFESSIONAL EXAMINATION.

14.  $\frac{1}{2} \log \frac{1}{2}$

clinical cases (a written report being made in one case giving history, diagnosis, prognosis, treatment, one case being treated at home, being written up as follows: in 1870, a patient was referred to me and was found to have a large, hard, indurated, and painful swelling of the right testis, which was found to be a carcinoma of the testis. The patient was treated with iodine and had a complete cure. The patient was followed up for several years and was found to be well. The patient was then referred to me again and was found to have a large, hard, indurated, and painful swelling of the left testis, which was found to be a carcinoma of the testis. The patient was treated with iodine and had a complete cure. The patient was followed up for several years and was found to be well.

## CONCLUSIONS

This follows the written work in early stages and the required presentation is then made in front of the class of the written and the oral presentation. The questions given are not the only ones to be asked. In some instances, they may be made good in the oral presentation. It is suggested that the required periods of approximately 15 min. each, and longer.

### III.—COLLATERAL EXAMINATION.

This embraces spelling, punctuation, the use of capital letters, grammar, arithmetic, geography (descriptive and physical), languages, history, general literature, elementary botany, geology, and zoology. While due credit is given for a knowledge of languages and the sciences it is not essential except in the case of physics, but a knowledge of the common school branches is essential. This examination will be omitted, in the discretion of the naval medical examining board, in the case of applicants holding diplomas or certificates from reputable literary or scientific colleges, normal schools, or high schools, or of graduates of medical schools which require an entrance examination satisfactory to the naval medical examining board.

The boards are required, under oath, to report on the physical, mental, moral, and professional qualifications of the candidate, so that the examinations are necessarily comprehensive, though simple and practical, and not beyond the attainments of any well educated physician. The oral and written questions are similar to those asked by the best medical colleges in examinations for graduation. A successful candidate, upon completion of his examination, will be notified by the president of the board that he has been found qualified. With the consent of the board, a candidate may withdraw at any period from further examination, and may at a future time present himself for reexamination. The board may conclude the examination (written, oral, and practical) at any time, and may deviate from this general plan as it may deem best for the interests of the naval service. No allowances will be made for the expenses of persons appearing for examination. The tenure of office in the Medical Corps of the Navy is for life, unless sooner terminated by removal, resignation, disability, or other casualty. All commissioned officers of the navy, including the Medical Corps, are retired from active service at the age of sixty-two years, and when so retired (or when retired from active service for disability or other casualty contracted in line of duty before that age) receive an annual pay for life amounting to three fourths of the highest pay of their grade at the time of retirement. When any officer of the navy, including medical officers, has been thirty years in the service, he may, upon his own application, in the discretion of the President, be retired from active service and placed upon the retired list with an annual pay for life amounting to three fourths of the highest pay of his grade at the time of retirement. Upon the death from wounds or disease contracted in line of duty of any officer, including medical officers (and immediately upon official notification thereof, there will be paid to the widow of such officer, or any person previously designated by him, an amount equal to six months' pay at the rate received by such officers at the date of his death, less \$75 to defray expenses of interment; but the residue, if any, of the amount so reserved will be paid subsequently to the widow or other designated beneficiary. When traveling in the United States under orders, officers of the navy, including medical officers, receive 8 cents a mile to defray the expenses incident thereto, and when traveling by other than public conveyance at sea or outside the continental limits of the United States, such officers are allowed actual expenses, estimated on a liberal basis and in accord with the position of an officer, both as regards admissible items of expense and the cost of such items.

On entering the naval service medical officers are credited with five years' service (in recognition of the fact that they have been at their own expense in preparing themselves for government service) for the purpose of establishing their date of precedence as regards rank and for calculating their increase of pay for length of service, as follows: For every five years' service the pay of officers is increased 10 per cent. (though not to exceed 40 per cent.), calculated on the annual base pay of their grade, as shown in the appended table; but the pay of medical director is limited to \$5,000; that of medical inspector to \$4,500; and that of surgeon to \$4,000. When an officer goes to sea or leaves the continental limits of the United States under assignment to stations or for the performance of other duty beyond the continental limits, his pay is increased 10 per cent., and this increase is calculated upon the pay, including increases for length of service, which said officer may be receiving at the time of entering upon such duty or to which he may succeed by virtue of promotion or length of service during the performance of such duty, as shown in the

yond the continental limits of the United States does not fall under the statutory restrictions above mentioned, which control the increase of pay for length of service in the grades above passed assistant surgeon, and the operation of this benefit is shown in the second column of the appended table. The officers of the medical corps of the navy, and their respective base pays, upon which the figures of the appended table have been calculated, are as follows: Medical directors, \$4,000; medical inspectors, \$3,500; surgeons, \$3,000; passed assistant surgeons, \$2,400; and assistant surgeons, \$2,000. Assistant surgeons are examined at the expiration of three years' service for promotion, and if successful, become passed assistant surgeons. Promotions to the higher grades are made in the order of seniority to fill vacancies as they are created (by resignation, retirement, death, and the operation of the thirty year retirement privilege), and for each promotion a physical and professional examination is required by law. The examination for appointment is noncompetitive, but if two or more candidates are examined at the same time their appointments will be in the order of merit reported by the board.

For further information address the president of the naval medical examining board, U. S. Naval Medical School, corner Twenty-third and E streets, N.W., Washington, D. C., or the president of the naval medical examining board, U. S. Naval Hospital, Mare Island, Cal.

### PAY AND ALLOWANCE TABLE.

Rank and Length of Service	Pay per annum on shore.	Pay per annum at sea.	Allowances (per annum for quarters.)
Assistant surgeons, rank of lieutenant (junior grade) .....	\$2,200	\$2,420	\$432
Passed assistant surgeons, rank of lieutenant .....	2,640	2,904	576
After 5 years in the service .....	2,880	3,168	576
After 10 years in the service .....	3,120	3,432	576
Surgeons, rank of lieutenant commander .....	3,600	3,960	720
After 10 years in the service .....	3,900	4,290	720
After 15 years in the service .....	4,000	4,400	720
Medical inspectors, rank of commander: .....			
After 15 years in the service .....	4,500	4,950	864
Medical directors, rank of captain: .....			
After 15 years in the service .....	5,000	5,500	1,008
Surgeon general, rank of rear admiral .....	6,000	6,600	1,152

NOTE.—There are also liberal allowances for fuel and light when on shore, at home, and beyond the continental limits of the United States, the amount varying according to rank, season, and the latitude of the station at which the officer is serving.

Both within and (on shore duty) beyond the continental limits of the United States, but only when quarters are not furnished by the Government.

The requirements are substantially the same in the case of applicants for appointment as acting assistant surgeon, and they may at any time subsequent to their appointment be ordered for examination for the grade of regular assistant surgeon.

**Resolutions Adopted at the Death of Dr. Farrington.**—At a meeting of the Harlem Medical Association, held June 3, 1908, the following minutes and resolutions were adopted:

*Whereas*, Death has removed from among us a former president and one of the founders of this association, Dr. Joseph Oakley Farrington, unusually long and favorably known, and highly respected by us, therefore, be it

*Resolved*, That we deeply regret the loss the association has sustained in the death of its second president, who enjoyed the fruits of his profession for over half a century;

*Resolved*, That the association extends its sympathy to the family of the deceased, and that a copy of these resolutions be spread in full upon the minutes of this association; that they be forwarded

FIELD, P. C., Captain. Ordered to accompany Seventh Infantry to duty at manœuvre camp, Chickamauga Park, Ga.

RAYMOND, H. L., Major. Ordered to return from treatment at Washington, D. C., to Columbus Barracks, Ohio.

SCHREINER, E. R., Captain. Assigned to temporary charge of San Francisco Medical Supply Depot, during the absence of Lieutenant Colonel D. M. Appel, medical corps.

### Navy Intelligence:

*Official list of changes in the stations and duties of officers of the medical corps of the United States Navy for the week ending June 13, 1908:*

BARBER, G. H., Surgeon. Detached from course of instruction at the naval medical school, Washington, D. C., and ordered to the Naval Hospital, Boston, Mass.

BLACKWELL, E. M., Passed Assistant Surgeon. Detached from course of instruction at the naval medical school, Washington, D. C., and ordered to report in that city on June 15th for examination for promotion, and then to await orders.

BOGERT, E. S., Surgeon. Detached from course of instruction at the naval medical school, Washington, D. C., and ordered to the naval war college, Newport, R. I.

BROWN, E. M., Assistant Surgeon. Detached from course of instruction at the naval medical school, Washington, D. C., and ordered to the Naval Hospital, Norfolk, Va.

BUNKER, C. W. O., Assistant Surgeon. Detached from the naval academy and ordered to the *Arkansas*.

CLARK, G. F., Acting Assistant Surgeon. Appointed an acting assistant surgeon from June 6, 1908.

COLE, H. W., Jr., Assistant Surgeon. Detached from course of instruction at the naval medical school, Washington, D. C., ordered home, and granted leave for one month.

DONELSON, M., Assistant Surgeon. Detached from the *Porter*, and ordered to the *Biddle*.

DUHIGG, J. T., Assistant Surgeon. Ordered to the naval recruiting station, Los Angeles, Cal.

FAUNTILERY, A. M., Passed Assistant Surgeon. Detached from course of instruction at the naval medical school, Washington, D. C., and ordered to the naval medical school hospital, Washington, D. C.

FREEMAN, G. F., Passed Assistant Surgeon. Detached from course of instruction at the naval medical school, Washington, D. C., and ordered to the navy yard, Boston, Mass.

LANE, H. H., Assistant Surgeon. Ordered to duty in the department of government and sanitation, Canal Zone, Panama.

MCDOWELL, R. W., Assistant Surgeon. Ordered to the Naval Hospital, Philadelphia, Pa.

MELHORN, K. C., Assistant Surgeon. Detached from the *Wabash* and ordered to the *Yankee*.

PECK, A. E., Passed Assistant Surgeon. Detached from the naval station, Cavite, P. I., and ordered home.

SELLERS, F. E., Assistant Surgeon. Detached from the naval academy and ordered to the *Nevada*.

SMITH, G. T., Surgeon. Detached from course of instruction at the naval medical school, Washington, D. C., and ordered to the Naval Hospital, New York, N. Y., July 1.

SNYDER, J. J., Passed Assistant Surgeon. Detached from course of instruction at the naval medical school, Washington, D. C., and ordered to report in that city June 15th, for examination for promotion, and then to await orders.

STALNAKER, P. R., Assistant Surgeon. Detached from course of instruction at the naval medical school, Washington, D. C., and ordered to report in that city June 15th, for examination for promotion, and then to await orders.

TAYLOR, J. L., Assistant Surgeon. Detached from course of instruction at the naval medical school, Washington, D. C., and ordered to report in that city, June 15th, for examination for promotion, and then to await orders.

VERNEK, W. W., Passed Assistant Surgeon. Resignation accepted from June 10, 1908.

WILSON, G. B., Surgeon. Detached from the course of instruction at the naval medical school, Washington, D. C., and ordered to the *Wabash*.

## Births, Marriages, and Deaths.

### Born.

SHOOK.—In Pinar del Rio, Cuba, on Saturday, May 30th, to Dr. J. Ralph Shook, United States Army, and Mrs. Shook, a daughter.

### Married.

ALBEE—SUMMEY.—In Philadelphia, on Saturday, June 6th, Dr. William Albee and Miss Nellie Summey.

ATWELL—MURDOCK.—In Fly Creek, New York, on Wednesday, June 3d, Dr. Floyd Jerome Atwell and Miss Helen Williams Murdock.

CARLTON—WINSTEAD.—In Rocky Mount, North Carolina, on Tuesday, June 9th, Dr. J. Lane Carlton, of Salisbury, and Miss Meta May Winstead.

COULTES—BRIGHAM.—In Philadelphia, on Wednesday, June 10th, Dr. J. F. Coultres and Miss Imogene Brigham.

CROFUTT—LAPE.—In Chicago, on Thursday, June 4th, Dr. Edward F. Crofutt, of New York, and Miss Janet D. Lape.

DOUGHERTY—MERKLEE.—In Philadelphia, on Wednesday, June 17th, Dr. Clarence C. Dougherty and Miss Florence Lillian Merklee.

GAGE—MORLEY.—In Troy, N. Y., on Wednesday, June 3d, Dr. George Henry Gage and Miss Ethel Morley.

GOOD—MUNDER.—In Philadelphia, on Wednesday, June 10th, Dr. William Harmar Good and Miss Helen Agnes Munder.

IVERSEN—SMITH.—In Palmyra, Nebraska, on Saturday, June 6th, Dr. John C. Iversen and Miss Catherine Smith.

JACKSON—STEVENS.—In Madison, Wisconsin, on Thursday, June 4th, Dr. Reginald Harry Jackson and Miss Elizabeth Breeze Stevens.

PORTER—MACMAHON.—In Washington, D. C., on Wednesday, June 10th, Dr. Frederick E. Porter, United States Navy, and Miss Lillian B. MacMahon.

WORSLEY—MUSSELMAN.—In Bethlehem, Pennsylvania, on Thursday, June 4th, Dr. A. Sweden Worsley, of Philadelphia, and Miss Bertha M. Musselman.

ZOLLER—HOFFMAN.—In St. Louis, Missouri, on Tuesday, June 2d, Dr. C. H. Zoller and Miss Philippine Hoffman.

### Died.

ALDRICH.—In Fall River, Massachusetts, on Saturday, June 6th, Dr. Nathaniel Borden Aldrich, aged forty-two years.

ANDERSON.—In Grosse Isle, Michigan, on Monday, June 8th, Dr. Frederick Pope Anderson, aged sixty-six years.

ASHLEY.—In Machias, New York, on Friday June 5th, Dr. Harmon J. Ashley.

AUSPITZ.—In New York, on Sunday, June 7th, Dr. Martin W. Auspitz, aged thirty-five years.

BLACKFORD.—In Middletown, Ohio, on Monday, June 8th, Dr. Harry Blackford, aged forty-two years.

CLOUGH.—In Honduras, Central America, on Saturday, May 30th, Dr. A. A. Clough, of Denver, Colorado.

DAVIE.—In Boston, on Thursday, June 4th, Dr. Charles H. Davie, of Scituate, Maine, aged sixty-five years.

FOLTZ.—In Cincinnati, Ohio, on Saturday, June 6th, Dr. Kent Oscanyan Foltz, aged fifty-one years.

GALT.—In Richmond, Virginia, on Monday, June 8th, Dr. T. A. D. Galt, aged seventy-four years.

GARDNER.—In Washington, D. C., on Wednesday, June 3d, Lieutenant Colonel William H. Gardner, Medical Corps, United States Army, aged seventy-one years.

MERCER.—In Pittsfield, Massachusetts, on Thursday, June 11th, Dr. William M. Mercer, aged sixty-five years.

NAUTZE.—In St. Louis, Missouri, on Sunday, June 7th, Dr. Gustave Nautze, aged thirty-eight years.

POSPISIEL.—In Washington, D. C., on Sunday, June 7th, Dr. Joseph Pospisiel, aged forty-five years.

REGENT.—In Chicago, on Friday, June 5th, Dr. Michael N. Regent, aged forty-four years.

STODDARD.—In Rochester, New York, on Saturday, June 6th, Dr. Enoch Vine Stoddard, aged sixty-eight years.

SHERMAN.—In Yonkers, N. Y., on Thursday, June 11th, Dr. William H. Sherman, aged forty-nine years.

SPOOR.—In Schenectady, New York, on Friday, May 20th, Dr. David E. Spoor, aged sixty-two years.

#### REVIEW OF THEORETICAL CONSIDERATIONS AND EXPERIMENTAL WORK RELATIVE TO OPSONINS WITH OBSERVATIONS AT THE SARANAC LABORATORY.\*

[Abstract.]

By E. R. BALDWIN, M. D.,  
Saranac Lake, N. Y.

The writer first drew attention to the fact that the view at first held, that opsonic substances were distinct from other ingredients of serum, is now doubted. Dean, Cowie, and Chapin, Sleeswijk, and Levaditi have shown that the normal serum has opsonic functions associated with the normal amboceptor and complement which cannot be separated from them. Heat and absorption affect them to the same degree as the opsonic activity. The substance favoring phagocytosis need not be assumed to be wholly distinct, because chemical and physical differences in bacteria may account for varying manifestations, sometimes phagocytic, at others bactericidal or agglutinating. The opsonic and complement functions are regarded as indistinguishable by Muir and Levaditi. There is more reason to think that immune or specific opsonic functions are due to separate substances. Their presence may be demonstrated when corresponding lysins and agglutinins are absent or removed, as shown by Neufeld and Topfer and Hecht.

Even here differences in the chemical or physical affinities or experimental limitations may obscure the relations of these antifections due to a single substance. In most immune sera removal of immune amboceptors by absorption is accompanied by a simultaneous loss of lytic, agglutinative, and opsonic functions. The general result of such experiments has been to class the specific opsonins with the amboceptors, whether identical or not with the lysins, etc., is difficult to prove.

The subject is of importance because of the use of the opsonic index as a standard of resistance, and in diagnosis. The practical value in this clinical application has lessened, as further study reveals its limitations. If it is the best it is yet a very imperfect standard, and other factors must be reckoned of considerable importance. The majority of clinical

studies published will not bear criticism for accuracy, as shown by mathematical calculations (see *Cambridge Committee Report*). In some local infections with tubercle bacillus and cocci the opsonic estimations have appeared useful in diagnosis and treatment. In progressive or generalized infections the results have been of doubtful value. C. P. Ritchie has successfully applied the method of absorption followed by opsonic estimations for diagnosis. It is analogous to that of Bordet and Gengou recently employed by Wassermann in lues diagnosis, except that the phagocytic test is substituted for the hæmolytic one.

Experiments at the Saranac Laboratory reported last year on the effect of opsonized tubercle bacilli have been confirmed and extended. Virulent tubercle bacilli treated with the fresh serum of an immunized cow produce more decided reactive inflammation when inoculated into rabbits' corneæ, in comparison with controls, and weak virulent bacilli treated in like manner appeared to be slightly more protective to guinea pigs subsequently inoculated to test their immunity.

The reaction described is characterized by an increased leucocytosis, whether beneficial or not to the animal is undetermined, but presumably it is conservative. Morphological changes in the bacilli were not demonstrated by staining.

Dr. Kinghorn and Dr. Twichell have made clinical studies with the tuberculoopsonic index in sixty-three supposedly healthy persons and in thirty-six tuberculous patients, controlling their technique frequently by duplicate tests of four to six preparations of the same serum.

They found a range from 0.02 to 1.04 in the healthy sera, and from 0.26 to 2.26 in the tuberculous.

They also made daily estimations of the sera of seven persons six or seven days before and after the subcutaneous tuberculin test for diagnosis. No regular reaction curve was detected, though after a tuberculin reaction the index was generally higher. Likewise in eleven patients undergoing tuberculin treatment without reference to the index, no characteristic or uniform curve was manifest. Their ascertained average technical error was  $\pm 4$  per cent, as determined from duplicate tests. Their results do not encourage the expectation of much practical use of the index in pulmonary tuberculosis in the usual method of its application.

\*Read at the annual meeting of the Association of American Physicians, Washington, D. C., May 15, 1907.

## THE OPSONIC TREATMENT OF DISEASE.

*With a Report of Thirty Cases.\**

By G. MORTON ILLMAN, M. D.,

Philadelphia,

Lecturer on Clinical Medicine, Temple University; and Associate  
Physician to the Garretton Hospital;

AND HARRY A. DUNCAN, A. B., M. D.,

Philadelphia,

Director of the Clinical Laboratory, Samaritan Hospital.

In reporting the following cases treated by vaccine therapy we do so with the full appreciation of the fact that at the present time the prognosis in the cases considered cured can only be problematical, and that time only will decide whether the results obtained will be permanent.

Certain it is, however that at present prompt beneficial results can be produced in many conditions that have in the past been considered almost hopeless as regards a complete cure.

Some of the cases here submitted were treated nearly one year ago, and it is indeed gratifying to note that in the majority of them there is absolutely no tendency to a return at the present time. This article, therefore, is not a review of the massive quantity of literature on this subject, which is at present attracting so much attention, nor is it to be considered in the light of a criticism of the many excellent methods or modifications of Wright's opsonic technique as originally advised by him, but rather as an honest report of our experiences in the treatment of any and all the cases that are from time to time referred to us for treatment. Our technique, with but few modifications, has been essentially the same as that advised by Wright. Many of the cases were exceedingly resistant to all other forms of treatment, and for this reason we have endeavored to reduce the treatment by vaccines to a more definite clinical basis, employing in each case the minimum amount of technique necessary to obtain a good result.

Taking an average of the frequency of doses and strength of vaccine used by other investigators and reported by them from time to time (and adhering to the suggestions given by Wright), we administered our vaccine every seventh to fourteenth day, depending upon the clinical condition, or opsonic index, or both, of the patient at the time of the treatment.

Many times the clinical condition of the patient would be excellent, but the index low, and invariably when the patient returned to the clinic there would be a renewal of a discharge from a sinus which would have been impossible to forecast from the clinical symptoms alone the week previous.

It is the better plan, therefore, in *doubtful* cases to first make a study of the "opsonic" condition of the patient before instituting any form of vaccine injections. Our experience with a case in which no opsonic index was taken and a large initial injection given purely upon the clinical evidence present was somewhat as follows:

The case was that of a colored woman; age thirty-nine years. She had been operated upon for an empyema eighteen years ago, with a negative result. Five subsequent operations had also failed to give relief. The outlet of the con-

stantly discharging sinus was just below and to the left of the right scapula. A culture showed the presence of the *Staphylococcus aureus* (the empyema was probably tuberculous in origin). Clinically the patient was in the best of health, and the sinus seemed to be the only thing that prevented the free use of the right shoulder and arm. She was given an injection of 200 million *Staphylococci aurei*. This was followed by a severe reaction within the following six hours, which made it necessary for the patient to go to bed, where she remained for seven days. She complained at first of a chill, followed by vertigo and severe rheumatic pains in the right shoulder and arm. Ten days later, however, her improvement was so marked that she was led to exclaim that "she had not felt so well in the past ten years." An examination of the sinus at this time showed the discharge from the sinus to have almost stopped (one or two drops on a dressing in twenty-four hours), and no pain whatever in the arm or shoulder.

That a fatal result did not follow the first injection given in this case was due more to good fortune than good management, and our experience with other cases simulating this one has taught us that in treating cases from the clinical standpoint one should begin with very small doses of any and all vaccines and gradually enlarge the dose with each subsequent injection. More especially should this routine be observed in cases where the lesion is of very long standing. To suddenly arouse a sleeping infection of eighteen years' standing with a large initial dose of vaccine as was done in this case is the very thing to be avoided if a favorable result is to be finally obtained.

It is our practice at present to study the "phase" of the patient, especially in cases where the lesion has existed over a very long period. This we think is the better policy to pursue until opsonic treatment has more firmly established itself favorably in the opinion of the profession, or to that place in therapeutics which it so well deserves, for with such definite scientific means at hand for determining beforehand the possible effect of treatment the death rate should practically be negative. It was the inability to determine the opsonic condition of a patient in former years that caused such a revulsion of feeling toward Koch's tuberculin. The very same administered now always under favorable circumstances is productive of nothing but good results when tuberculin is indicated.

The number of diseases in which opsonic treatment is curative or beneficial is already large, but the present indications are that opsonic work will not only be used more and more extensively in the treatment of disease, but also in the diagnosis, as is now seen in the treatment and diagnosis of tuberculous conditions.

Of the entire group of cases herein reported thirteen were tuberculous; the remainder were as follows: Gonorrheal, five; colonic, one; staphylococci, six; streptococci, three; staphylococci and streptococci, one; typhoid fever, one.

The one case of typhoid fever is reported because it is typical of the negative results obtained in all other cases that we have attempted to abort with vaccine injections. The case reported was one in which everything seemed clinically to favor vaccine treatment. We could not see any improvement, however, that could not have taken place in any other typhoid case without vaccine treatment.

Our technique, briefly, is as follows: We first make a thorough physical examination of the pa-

\*Read before the Samaritan Hospital Medical Society, March 28, 1928.

tient and study carefully the personal and family history. The finger or lobe of the ear is then punctured and the blood allowed to flow freely into a Wright's tube. This is then conveyed quickly to the laboratory and centrifuged. The serum thus obtained is kept at 37° C. and used as promptly as possible. The opsonic index for tuberculosis, staphylococci and streptococci infections, etc., is then determined (in the manner now so familiar to all clinicians and laboratory workers), depending upon the diagnosis of the condition when possible by means of cultures and clinical phenomena. As before stated, the index itself is often most helpful in making a correct diagnosis. If the index is low and is stationary, say 0.6 or 0.7, and the clinical symptoms warrant it, without a repeated series of more than two or three index observations being made, we give the patient the first injection.

A point on the left arm about four inches above the elbow is usually selected, and the skin thoroughly cleaned with sterile water, followed by alcohol and again by sterile water. A drop of pure carbolic acid is then applied for a moment or two. This acts both as an anæsthetic and antiseptic. The needle is then thrust well into the subcutaneous tissue, the injection slowly given, and the needle quickly withdrawn, a piece of sterile cotton being held at the point of puncture until the vaccine is completely absorbed.

Our reason for selecting the arm in the region usually employed for vaccination purposes is because of the fact that the patient becomes less suspicious and alarmed should there be any local urticaria or irritation following the injection, the patient being more apt to consider the local trouble as a natural sequel to a process which he usually believes to be nothing more or less than a form of vaccination.

In our treatment of tuberculous cases we have had more uniform results with tuberculin T. R. than with the other forms of tuberculin when using stock vaccines. The average dose employed in adults is 0.001 milligramme, and we have seldom had to change this dose in order to get good results and cause a gradual rise in the index. One one thousandth of a milligramme has never given any disagreeable reaction, and we think that a course of treatment which is never productive of a reaction produces better and more prompt results than when the reverse is the case.

In our treatment a year ago we used very large doses of vaccine (one or two of the cases are included in the appended list), which were productive often of a very severe reaction, but followed promptly in many cases by a fall of temperature and improvement of symptoms. The results, however, were not always permanent, so that we now feel convinced that small initial doses at least should always be employed, but that in some cases doses much larger than those recommended by Wright must be used to bring about a good, permanent result.

We have employed the following minimum and maximum doses:

Bacilli coli, 5,000,000 to 10,000,000 million; pneumococci, 5,000,000 to 20 million; staphylococci, 5,000,000 to 10,000,000 million; streptococci, 5,000,000 to 15,000,000 million; typhoid bacilli, 5,000,000 to 1,000 million.

In all of the cases here reported, except Nos. IV, XXI, XXIV, XXIX, and XXX, we used "stock vaccines," and for the supply of the same we are greatly indebted to Parke, Davis & Co. and the H. K. Mulford Company. By using stock vaccines the work is made much less complicated and greatly facilitated, as it takes considerable time to accurately produce autogenous vaccines.

We feel that in the majority of instances the stock vaccines are in every respect just as effective as autogenous vaccines, and we make it a rule to put all cases at first on stock vaccines. This failing, as it does now and then in complicated cases, we put the patient on vaccines made from his own cultures.

We must not, however, in these complicated cases condemn our stock vaccines too quickly merely because we do not get a prompt response to treatment, for in many cases our failure to get results is not because of the fact that we are using a stock vaccine, but because we have failed to employ that vaccine or mixture of vaccines which corresponds to the variety of infection to be treated. For example, given a profuse discharge from a sinus which cultures show us contains streptococci and staphylococci—if the streptococcus is the predominant organism in the production of the condition, staphylococci vaccine given indefinitely would raise the staphylococci opsonic index, but give little or no result, or only in proportion to the activity displayed by the staphylococcus in the etiology of the sinus. Study carefully the index and its relation to a mixed infection, and then use a stock vaccine corresponding to the infection, and usually a prompt improvement is noted.

Again, in other cases we may get a history in a given case which is decidedly tuberculous in detail, and we give repeatedly tuberculin, or tubercle bacilli, which produces a prompt rise in the tuberculoopsonic index, but no clinical improvement. An osteomyelitis, tuberculous in character, may be continued for years by being contaminated with a second or third infection (usually staphylococcus) which finally becomes the predominating infection, and a change to staphylococci vaccine, or a mixture of the same with tuberculin, causes a prompt, satisfactory result.

### Summary of the Cases Reported.

1. Tuberculosis	1	2. Staphylococci	1
3. Streptococci	1	4. Typhoid	1
5. Mixed	1	6. Pneumococci	1
7. Bacilli coli	1	8. Tuberculin	1
9. Total	1	10. Total	1
11. Total number of cases	1	12. Total number of cases	1

### Conclusions.

That vaccine therapy offers a chance of cure in many cases of disease hitherto regarded as incurable.

That in the large majority of cases good results are just as efficient as autogenous vaccines.

That cases can be treated with fewer actual index observations than was at first supposed.

That cases treated with the clinical phenomena alone as a guide should only be so treated by some one well versed in vaccine therapy, and then only after having been under previous observation for a period long enough to have determined "the phase" the patient is in.

That very small initial doses should be employed when the opsonic index has not been previously determined.

That the best results at the present time are obtained in tuberculous conditions and staphylococci or streptococci infections, as in acne, etc.

That to get the best results vaccine treatment must be instituted as soon as the diagnosis is made.

CASE I.—J. P., male, age sixteen years.

Family and personal history were negative.

Present illness: Osteomyelitis of right femur. Had been treated for seven years locally by incisions, curetting, and drainage. Five injections of tuberculin T. R., 0.001 mg. at each dose, extending over a period of five weeks, caused a complete cessation of the discharge and an apparent cure. The tuberculoopsonic index during this time was raised from 0.7 to 1.4. A sudden drop of the index was promptly followed by a small abscess a short distance from the original sinus. This promptly healed after one more injection of the tuberculin T. R., and the patient to-day is in the best of health and has again resumed active work.

CASE II.—F. M., colored, female, age twenty-six years.

Family and personal history were negative.

Present illness: Pott's disease with a discharging sinus.

May 28, 1907—Tuberculoopsonic index, 0.8; given 0.001 mg. tuberculin T. R.

June 1, 1907—Tuberculoopsonic index, 0.85; given 0.001 mg. tuberculin T. R.

June 18, 1907—Tuberculoopsonic index, 0.95; given 0.001 mg. tuberculin T. R.

July 9, 1907—Patient better, discharge less; given 0.001 mg. tuberculin T. R.

July 24, 1907—Very little discharge noticed; given 0.001 mg. tuberculin T. R.

August 30, 1907—Sinus closed, had gained twenty pounds in weight. The cure in this case was very gradual and progressive. The final result to date is perfect.

CASE III.—B. H., age four years, female.

Family history was negative.

Personal history: Had tonsils removed one year ago.

Present illness: Cervical adenitis.

May 29, 1907—Tuberculoopsonic index, 0.65; given 0.001 mg. tuberculin T. R.

The first injection was followed by marked improvement clinically.

June 1, 1907—Tuberculoopsonic index, 0.75; given 0.001 mg. tuberculin T. R.

June 11, 1907—Reported to be in excellent condition and has had no return to date.

CASE IV.—E. T., female, age twenty-two years, colored. Admitted to Samaritan Hospital April 23, 1907.

Family and personal history were negative.

Present illness: Tuberculous peritonitis.

May 2, 1907—Tuberculoopsonic index, 0.5; given 15,000 million tubercle bacilli.

May 10, 1907—Tuberculoopsonic index, 0.55; given 15,000 million tubercle bacilli.

May 12, 1907—Tuberculoopsonic index, 0.65.

May 16, 1907—Tuberculoopsonic index, 0.85.

May 17, 1907—Given 15,000 million tubercle bacilli. Discharged from the hospital.

May 27, 1907—Slight recurrence of symptoms. Tuberculoopsonic index, 0.75.

May 28, 1907—Given 7,000 million tubercle bacilli.

March 20, 1908—The patient's physician says she has been practically well for the past ten months and has gone south to live.

Average temperature on admission, 103° F. After starting treatment, average temperature, 99° to 100° F.

CASE V.—E. H., female, age nine years.

Family and personal history were negative.

Present illness: Began to notice swelling on left side of neck six months ago, following a toothache. Tooth was extracted. Gland finally broke down and began to discharge three months after extraction of the tooth. Patient was treated with various ointments and dressings for several weeks with a negative result. She was then given a course of x ray treatment with negative results. When we first saw her the broken down area was constantly enlarging and discharging profusely.

November 11, 1907—Tuberculoopsonic index 0.8; given 0.001 mg. tuberculin T. R.

November 23, 1907—Tuberculoopsonic index, 0.8; given 0.001 mg. tuberculin T. R.

November 30, 1907—Tuberculoopsonic index, 1.5; given 0.001 mg. tuberculin T. R.

December 7, 1907—Tuberculoopsonic index, 1.9; given 0.001 mg. tuberculin T. R.

December 14, 1907—Tuberculoopsonic index, 1.6; given 0.001 mg. tuberculin T. R.

January 11, 1908—Tuberculoopsonic index, 2.0; given 0.001 mg. tuberculin T. R.

January 25, 1908—Tuberculoopsonic index, 2.0; given 0.001 mg. tuberculin T. R.

February 1, 1908—Tuberculoopsonic index, 2.1; given 0.001 mg. tuberculin T. R.

February 8, 1908—Tuberculoopsonic index, 0.9; given 0.001 mg. tuberculin T. R.

February 15, 1908—Tuberculoopsonic index, 0.8; given 0.001 mg. tuberculin T. R.

February 29, 1908—Given 0.001 mg. tuberculin T. R.

In this case injections were given more according to the clinical symptoms than according to the index, and although the index fell decidedly toward the last the gland had healed completely and left scarcely a mark to show from where the discharge had taken place.

CASE VI.—M. S., male, age seventeen years.

Family and personal history were negative.

Present illness: Was attacked with tuberculosis of both tibia nine years ago. Both legs operated on: right leg recovered, but left tibia still discharged. It was red, painful, swollen, and discharged freely.

November 11, 1907—Tuberculoopsonic index, 0.7; given 0.001 mg. tuberculin T. R.

November 16, 1907—Tuberculoopsonic index, 1.1.

November 20, 1907—Tuberculoopsonic index, 1.1; given 0.001 mg. tuberculin T. R.

November 30, 1907—Tuberculoopsonic index, 1.5; given 0.001 mg. tuberculin T. R.

December 7, 1907—Tuberculoopsonic index, 0.7.

December 21, 1907—Tuberculoopsonic index, 1.5; given 0.001 mg. tuberculin T. R.

January 4, 1908—Tuberculoopsonic index, 0.9; given 0.001 mg. tuberculin T. R.

February 1, 1908—Tuberculoopsonic index, 1.1; given 0.001 mg. tuberculin T. R.

February 15, 1908—Tuberculoopsonic index, 1.2; given 0.001 mg. tuberculin T. R.

Recovery complete.

CASE VII.—J. R., age fourteen years.

Family history was negative.

Personal history and present illness: Four years ago four ribs on the right side were removed; cause, tuberculosis of ribs and pleura. He had a profuse, offensive discharge from a large persistent sinus.

May 27, 1907—Tuberculoopsonic index, 0.75; given 0.001 mg. tuberculin T. R.

May 28, 1907—Tuberculoopsonic index, 0.7.

June 3, 1907—Tuberculoopsonic index, 0.7; given 0.001 mg. tuberculin T. R.

June 10, 1907—Tuberculoopsonic index, 0.8; given 0.001 mg. tuberculin T. R.

June 21, 1907—Tuberculoopsonic index, 0.85; given 0.001 mg. tuberculin T. R.

June 21, 1907—Gained four pounds in weight; marked general improvement.

August 23, 1907—Condition very much improved.

August 23, 1907—Given 0.001 mg. tuberculin T. R.

December 14, 1907—Tuberculoopsonic index, 1.5; given 0.001 mg. tuberculin T. R.

December 21, 1907—Had attack of influenza. Tuberculoopsonic index, 0.7.

December 21, 1907—Given 400 million mixed staphylococci vaccine.

December 28, 1907—Tuberculo index and staphylococcic index, 1.5.

December 28, 1907—Given 0.001 mg. tuberculin T. R.

December 31, 1907—Given 100 million staphylococci mixed.

January 11, 1908—Tuberculo index, 1.2.

January 8, 1908—Given 100 million staphylococci mixed.

January 11, 1908—Staphylococcic index, 1.9.

January 16, 1908—Given 0.001 mg. tuberculin T. R.

January 25, 1908—Tuberculo index, 0.9. Still considerable discharge noticed.

To be put on autogenous vaccine.

CASE VIII.—G. C., male, age fifty-four years, colored janitor.

Admitted to hospital October 22, 1907.

Diagnosis: Tuberculous laryngitis.

Family history was negative.

Previous personal history: Had rheumatism ten years ago. One year ago "took cold," severe cough and dyspnea.

Present illness, cough, dyspnea, and pain in the back.

Physical examination: Impaired resonance at right apex. Right side posterior, sibilant and bubbling râles. Heart, apex diffuse, accentuated second pulmonic. Throat, tuberculous infiltration between the arytenoid cartilages, bases, and epiglottis.

Average temperature, 99° F.; highest temperature, 101.6° F.

November 3, 1907—Tuberculoopsonic index, 0.6; given 0.001 mg. tuberculin T. R.

November 28, 1907—Tuberculoopsonic index, 0.85; given 0.001 mg. tuberculin T. R.

December 7, 1907—Tuberculoopsonic index, 0.95; given 0.001 mg. tuberculin T. R.

Left the hospital. While in the institution his improvement was consistent with the gradual rise in the index.

The aphonia had disappeared.

CASE IX.—N. B., age sixty-two years, male.

History was negative.

Present illness: Tuberculosis of lower third of ulna for four years. Had had several operations. Two sinuses were present, one discharging to outside of forearm, and the other to the inside.

November 23, 1907—Tuberculoopsonic index, 0.8; given 0.001 mg. tuberculin T. R.

November 30, 1907—Tuberculoopsonic index, 0.9; given 0.001 mg. tuberculin T. R.

December 7, 1907—Tuberculoopsonic index, 1.0; given 0.001 mg. tuberculin T. R.

December 14, 1907—Tuberculoopsonic index, 1.2; given 100 million *Staphylococcus aureus*.

December 28, 1907—Tuberculoopsonic index, 1.0; given 0.001 mg. tuberculin T. R.

January 11, 1908—Tuberculoopsonic index, 1.5; given 0.001 mg. tuberculin T. R.

February 22, 1908—Tuberculoopsonic index, 1.2; given 100 million *Staphylococcus aureus*.

February 29, 1908—Tuberculoopsonic index, 1.2; given 0.001 mg. tuberculin T. R.

March 7, 1908—Given 0.001 mg. tuberculin T. R.

March 14, 1908—Given 0.001 mg. tuberculin T. R.

Responded to treatment but was not cured.

CASE X.—W. J., male, age twenty-one years, machinist.

Admitted to the Samaritan Hospital November 13, 1907.

Family and previous medical history were negative.

Diagnosis: Tuberculous peritonitis.

Present illness began one year ago with a pain in the left side, made worse by motion. Now had night sweats and severe pain just below the epigastrium when coughing.

Temperature on admission, 101° F. Average temperature, 100.5 to 101° F. Tubercle bacilli could not be found in the sputum, white blood corpuscles 7,600.

November 28, 1907—Tuberculoopsonic index, 0.65; given 0.001 mg. tuberculin T. R.

November 29, 1907—Given 0.001 mg. tuberculin T. R.

Some reaction noticed after the injection and still no better after one month. Temperature 101° F. The reaction tem-

perature after the injection, however, was not noticed.

The result was negative. Patient left the hospital with a temperature of 100° F.

CASE XI.—R. L., female, age twenty-four years.

Family and personal history were negative.

Present illness: Had had pain in right hip joint for past

two years; some shortening; general health good. No local symptoms of inflammation.

Diagnosis: Tuberculosis of the hip joint.

Tuberculoopsonic index, 0.6.

Patient was given four injections of tuberculin T. R., 0.001 mg., at intervals of seven days. Opsonic index after the fourth treatment, 1.2. The patient stopped coming for treatment because she said that after each injection she had severe pain for twenty-four hours in the affected joint. Result negative.

CASE XII.—H. S., female, age two and one half years.

History was negative.

Present illness: Tuberculosis of lower maxilla.

November 10, 1907—Tuberculoopsonic index, 0.8; given 0.005 mg. tuberculin T. R.

November 17, 1907—Tuberculoopsonic index, 0.8; given 0.001 mg. tuberculin T. R.

November 23, 1907—Tuberculoopsonic index, 0.9.

The child cried and opposed the injections to such an extent that we stopped treatment.

CASE XIII.—W. S., male, age eleven years.

History was negative. Diagnosis: Tuberculosis of the hip.

Present illness began five years ago after a fall on the hip, with excessive discharge, and he has been wearing a cast for five years.

November 15, 1907—Tuberculoopsonic index, 0.9; given 0.001 mg. tuberculin T. R.

November 30, 1907—Tuberculoopsonic index, 0.95; given 0.001 mg. tuberculin T. R.

December 7, 1907—Tuberculoopsonic index, 0.7.

December 21, 1907—Tuberculoopsonic index, 1.1; given 400 million *Staphylococcus aurei*.

December 28, 1908—Tuberculoopsonic index, 1.2; given 0.001 mg. tuberculin T. R.

January 4, 1908—Given 300 million *Staphylococcus aurei*.

January 11, 1908—Tuberculoopsonic index, 1.7; given 0.001 mg. tuberculin T. R.

February 8, 1908—Tuberculoopsonic index, 1.1; given 0.001 mg. tuberculin T. R.

February 22, 1908—Tuberculoopsonic index, 1.4; given 300 million *Staphylococcus aurei*.

February 29, 1908—Given 0.001 mg. tuberculin T. R.

March 14, 1908—Given 0.001 mg. tuberculin T. R.

Marked improvement, but still had a slight discharge. Will be put on treatment with autogenous vaccine.

CASE XIV.—A., age thirty years.

Family and personal history were negative.

Present illness: Patient had gonorrheal arthritis of both ankle joints and both knee joints.

Two injections at intervals of seven days caused a complete amelioration of the symptoms and a marked general improvement, so much so that the patient said he did not want any more treatment, and if he should have a relapse, he said he would return.

CASE XV.—Mr. G., male, age forty-two years. Diagnosis: Chronic gonorrhea.

Family and personal history were negative.

He was treated locally from time to time and persistently for the past six months with a negative result. All the various astringents and combinations of the same gave no result.

January 7, 1908—Given 50 million gonococci.

January 21, 1908—Marked improvement as regards the quantity of the discharge.

January 21, 1908—Given 50 million gonococci.

January 28, 1908—Discharge diminished from seven 50 million gonococci. When last seen the discharge was two to three drops at intervals of three to four days.

Discharge did not stop until a further treatment.

CASE XVI.—E. M., male, age twenty years.

Family history and previous medical history were negative.

Present illness: For the past year and a half patient suffered with a severe suppuration of the testis, accompanied with a purulent, bloody discharge, which was at times very profuse.

Several of these discharges were two or three inches in length, were frequently passed.

Diagnosis: Gonorrheal proctitis, (chronic), and gonorrheal proctitis.

February 4, 1908—Given 100 million gonococci injected into the arm.

The index improved gradually until it reached 1.1. The discharge became less in quantity, but did not stop.

March 7, 1908.—We have stopped giving stock vaccine and he will now be given autogenous vaccine.

CASE XVII.—Mr. M., age forty years.

Family history was negative.

Previous medical history was one of exposure and infection.

Present illness: Suffering for twenty years with a posterior urethritis, prostatic abscess, and gonorrheal arthritis. Had to use crutches for a long time and local treatment gave only temporary relief. Ohlmacher gave him two injections of gonococci, which was followed by immediate and decided improvement. Business changes compelled him to come to Philadelphia.

With treatments that were very irregular as to time (patient was a traveling salesman), the improvement was very steady, the joint symptoms especially were clearing up, so much so that he now travels to a considerable extent for a mercantile house. The urethral discharge was less than when we first saw him.

CASE XVIII.—H. S., age forty years, male.

Family and personal history were negative.

Contracted gonorrhea in July, 1907; was given the usual course of treatment for this condition for six months. When we finally saw the patient he had a marked posterior urethritis.

January 4, 1908.—Gonorrheal opsonic index was 1.1. He was given 50 million gonococci every seventh day, followed by a steady improvement, but no cure effected. Index, March 1, 1908, 1.5. A careful culture study of the case will now be instituted and the stock vaccine replaced by autogenous vaccine.

CASE XIX.—Mrs. S., age thirty-eight years.

Family and personal history and previous medical history were negative.

Present illness: Had suffered with pustular acne of the face and neck for twenty-three years, and had been treated almost constantly during that time. High frequency current, ultra violet rays, and x rays had all been given a thorough trial with a negative result.

February 1, 1908.—When the patient presented herself for treatment the pustules were very numerous and many of them one half inch in diameter, containing much pus. Upon this clinical evidence she was given an injection of 300 million *Staphylococci citrei*. This was repeated in seven days, after which every papule and pustule on the face and many on the neck disappeared, leaving a smooth, nonindurated surface. She has now had six treatments. The face is perfectly normal and not a single new lesion has appeared.

CASE XX.—Mr. G., age twenty-one years.

Family and personal history were negative.

Present illness: Had been afflicted with a pustular acne of the face for the past three years.

December 11, 1907.—Given 300 million *Staphylococci citrei*.

December 18, 1907.—Given 300 million *Staphylococci citrei*.

December 25, 1907.—Given 300 million *Staphylococci citrei*.

January 2, 1908.—Given 300 million *Staphylococci citrei*.

January 6, 1908.—Given 300 million *Staphylococci citrei*.

January 9, 1908.—Cure complete.

CASE XXI.—Mr. A., age twenty-four years.

Family and personal history were negative.

Present illness: Pustular acne of the face of six years' duration.

June 4, 1907.—*Staphylococci* index, 0.7; culture showed *staphylococci*. Given 10,000 million *staphylococci* (autogenous).

June 10, 1907.—Given 10,000 million *staphylococci*. Some improvement noted.

June 17, 1907.—Given 10,000 million *staphylococci* (autogenous).

June 24, 1907.—Given 10,000 million *staphylococci*. Result negative.

CASE XXII.—Mr. D., age twenty-two years.

Family and previous medical history were negative.

Present illness: For five years had had acne pustulosa of the face. Many dark, infiltrated areas were noted. Was given three injections at intervals of seven days of 300 million *Staphylococci citrei*. The condition rapidly cleared up and the induration greatly improved when the

patient was attacked with pleurisy. For a period of three weeks he was confined to the house. At the end of this time a few papules again appeared on the neck. The injection was repeated and no new lesions appeared up to the present time.

CASE XXIII.—G. K., male, age twenty years.

History was negative.

Present illness: Infection of right side of the face and neck following the opening of a pimple. Culture showed *Staphylococcus albus* and *aureus*.

November 21, 1907.—*Staphylococci* opsonic index, 0.8; given 400 million mixed *staphylococci*.

November 23, 1907.—*Staphylococci* opsonic index, 0.9.

December 7, 1907.—*Staphylococci* opsonic index, 1.3.

Complete recovery.

CASE XXIV.—A. M., female, age twelve years.

Family history was negative.

Present illness: Osteomyelitis with metastatic abscesses. Temperature on admission to hospital was 105° F. Average temperature was 105° F. to subnormal.

Two days after admission tibia was scraped and drained. Temperature became normal for a period of two days, then began to rise and remit again.

Eighteenth day.—Hæmoglobin, 70; white blood corpuscles, 26,000; red blood corpuscles, 3,250,000.

Thirty-fourth day.—Patient became delirious.

Thirty-sixth day.—We were asked to see the patient. We made a culture which showed a mixed infection of *Staphylococcus aureus* and *streptococcus*.

Thirty-seventh day.—Patient was given 6,000 million mixed *staphylococci* and *streptococci* (autogenous).

Thirty-eighth day.—Rise of temperature from 99° to 103° F.

Thirty-ninth day.—Patient much better, slept well and took nourishment better.

Forty-second day.—Mental condition very good; temperature again falling to normal.

Forty-fourth day.—Autogenous vaccine again given, 12,000 million mixed *staphylococci* and *streptococci*, followed by a rise of temperature from 98.8° to 106.6° F.

Fiftieth day.—Temperature normal and remaining so for ten days; improvement of all symptoms.

Sixty-first day.—Temperature subnormal, 96° F. Physical examination showed enlarged liver, probably amyloid. Temperature for seven days 96° to 97° F.

Sixty-ninth day.—Patient died.

CASE XXV.—H., male, age eighteen years.

Family and personal history were negative. Diagnosis: Erysipelas.

Present illness: Patient had been treated for five days for typhoid fever when the case was referred to us. The face was greatly swollen, red, and oedematous on both sides and extended into the scalp. Temperature, 101° F.

November 15, 1907.—Patient was given 50 million *streptococci*.

The temperature remained at 101° F. for twenty-four hours, then fell to normal. The patient insisted on leaving the hospital and going home. The improvement was very decided, but we have been unable to locate the patient, which necessitates the record of the case as "improved" instead of "cured."

CASE XXVI.—Mrs. B., age twenty-eight years.

Family history was negative.

Personal history: Had an attack of erysipelas when three years of age.

Present illness: On fifth day of her puerperium the patient had a chill and some fever, with abdominal tenderness over the uterine region. A pelvic examination revealed an enlarged, tender uterus, and she was sent to the hospital and a curettoment done. The day following the operation the patient was attacked with facial erysipelas.

January 15, 1908.—Patient was given 50 million *streptococci*.

The temperature, which was 102° F., fell to normal within twenty-four hours, and it was found to be unnecessary to repeat the injection. A quick recovery followed and no further rise in temperature was noted after the first injection.

CASE XXVII.—Mr. T., age sixty-two years.

Family and personal history were negative.

Present illness consisted in a sinus following an operation for ischioanal abscess.

A culture showed the predominance of the *Staphylococ-*

*cus aureus*, and mixed staphylococci vaccine injections every seven days for four weeks raised the index from 0.7 to 1.4.

Not much improvement followed; autogenous vaccine is now being administered with improvement.

CASE XXVIII.—D. G., age five years, male.

History was negative.

Present illness: General infection of the arm following a puncture wound.

November 21, 1907—Streptococcic index, 1.1.

November 23, 1907—Given 25 million streptococci; followed by complete recovery.

CASE XXIX.—C. R., female, age thirty-six years.

Family history was negative.

Previous medical history: Had had a difficult labor eleven years ago; the pelvis was justomino.

Present illness: Eighteen months ago began to show symptoms of cystitis. Had an operation done for repair of a tear resulting from the difficult labor referred to; at the same time the bladder was irrigated, which was continued for some weeks. This was followed by improvement for a short time.

We now saw her for the first time. A retroverted uterus was replaced and the bladder carefully explored with the cystoscope and washed out with solution of silver nitrate. No relief was noted from this or subsequent irrigations.

A culture from the urine showed the presence of colon bacilli.

May 1, 1907—Colonopsonic index, 0.7.

May 2, 1907—Given 40,000 million colon bacilli. (Autogenous).

May 3, 1907—Index, 0.5; severe reaction followed this injection; the arm around the point of injection was swollen and inflammatory in character; cleared up with wet dressings; no pus.

May 9, 1907—Index, 1.1. Given 5,000 million colon bacilli.

May 21, 1907—Given 10,000 million colon bacilli.

June 10, 1907—Given 10,000 million colon bacilli.

Symptoms completely cleared up. Patient has remained absolutely healthy to the present time, March 15, 1908.

CASE XXX.—D., age twenty-seven years. Typhoid fever. Admitted to the Samaritan Hospital April 17, 1907, the ninth day of the disease. Temperature, 103° F.

April 20, 1907—Given 1,000 million typhoid bacilli; followed by a severe reaction, prolonged chill, and a rise of temperature, from 101° to 103.6° F. Had no apparent effect on the course of the disease. Temperature reached normal on the 21st day of the disease.

3235 NORTH FIFTEENTH STREET.

2721 WEST LEHIGH AVENUE.

## THE TUBERCULIN INUNCTION:

*A Diagnostic Measure without Rupture of Continuity or the Skin.*

By ERNST MORO, M. D.,

Munich,

Privatdocent in the University of Munich.

I rub into the skin of the chest or abdomen, over an area of 4 cubic inches, a piece of the following ointment of the size of a pea for about half a minute, and permit the ointment to remain on the surface of the skin to spontaneously absorb. The effect of this inunction is observed on the following day or later.

The ointment is prescribed thus:

R Koch's old tuberculin.

Anhydrous wool fat.

The result is positive when small papules appear over the area of the inunction or in its immediate vicinity; negative when the skin shows no changes of any kind. With the positive reaction one often observes only a few very pale papules. Occasionally the papules are very numerous and red, and only exceptionally the skin in the region of the inunction is very much reddened and itches. The papules

usually disappear at the end of a week. Other local or general symptoms have not been observed.

A positive result obtained by this method is as conclusive for a present or previous tuberculous infection as is that obtained by the conjunctival reaction or cutaneous method of von Pirquet.

By comparing the effects of my method and that of von Pirquet upon a large number of patients, the following differences were seen: (1) In advanced cases of tuberculosis the skin loses earlier its reactionary power to the inunction. (2) In cases showing no clinical signs of tuberculosis the percentage of positive results is much smaller in the inunction method.

As opposed to the conjunctival and subcutaneous applications the inunction is entirely harmless. The patients never object to its use.

My investigations have been only upon children. In the Munich medical clinics of Professor Friedrich von Müller and Professor Josef von Bauer, however, the efficiency of my method has been proved on adults.

23 MOZARTSTRASSE.

## THE OPHTHALMIC TUBERCULIN TEST.

By A. L. BENEDICT, M. D.,

Buffalo.

So many thorough discussions of this method have recently appeared that I merely wish to record a few clinical data:

CASE I.—Tuberculous tibia, moderate conjunctivitis in each eye, reaction doubtful.

CASE II.—Acne, very marked, in chronic alcoholic, delayed and probably adventitious conjunctivitis in eye opposite to that into which the tuberculin was instilled.

CASE III.—Typhoid, sixteenth day, nearly nonfebrile, no reaction.

CASES IV to XII.—Miscellaneous cases, mainly surgical, no suspicion of tuberculosis, no reaction.

CASE XIII.—Young woman, tuberculous since 1905, bacilli and cavity in summer of 1906, treated with Smith lymph, diet, etc., lungs let alone, no fever for some time, good general health, some moisture in region of cavity which I can no longer detect, practically no sputum; very marked but not serious reaction.

CASE XIV.—Young woman said to have had weak lungs, been "threatened with phthisis," and advised to give up dusty work on that account. I had not been able to find any lesion. Reaction negative.

CASE XV.—Young woman with acute exudative pleurisy, without assignable cause, in November. Apparently complete recovery after tapping. Reaction doubtful.

Cases II and XV illustrate a possible fallacy which I have not happened to see mentioned, namely, the occurrence of an adventitious conjunctivitis from dust, coryza, etc. Such causes may act so as to simulate not only a positive reaction, but, by affecting the uninstilled eye, to vitiate the contrast and thus perhaps lead to the recording of a negative or doubtful result. I do not overlook the fact that the very circumstantial descriptions have been given of the appearances to be looked for, but it seems probable whether these are sufficiently characteristic to be distinguished from a conjunctivitis of ordinary cause, especially when the latter occurs coincidentally.

The patient in Case XV took cold on the day of the instillation. Thus, while there was slightly more redness in the instilled eye, it was impossible to say whether this was due to the tuberculin or to a greater degree of extreme catarrhus, such as

is very frequently noted. The nostril corresponding also discharged slightly more. This suggests the query as to whether tuberculin, in the case of positive reactions, produces a corresponding unilateral rhinitis and even as to whether we may not apply the test nasally. If, as some state, "idiopathic" pleurisy is always tuberculous, we should certainly expect a marked reaction in this case.

156 WEST CHIPPEWA STREET.

## THE OPHTHALMIC REACTION IN THE DIAGNOSIS OF TUBERCULOUS CONDITIONS.

*With Special Reference to the Lungs and Skin.*

By HENRY HUBBARD PELTON, A. M., M. D.,

New York,

Adjunct Assistant Attending Physician to Bellevue Hospital; Chief of the Medical Clinic, Presbyterian Hospital, Out Patient Department.

Since Calmette's original papers<sup>1</sup> the ophthalmic reaction to tuberculin has become too familiar to the profession to need full description here. It is sufficient to state that, in general, when a small amount of sterilized one-half to one per cent. solution of dry tuberculin in normal saline solution is instilled into the conjunctiva of a patient who is the subject of tuberculous disease a local reaction takes place. In most instances where this positive reaction is obtained within three to forty-eight hours after the instillation, the semilunar fold and caruncle become reddened and the conjunctiva becomes congested, the general appearance being that of an acute infectious conjunctivitis. The reaction reaches its height in from six to ten hours, and, as a rule, disappears in from eighteen to thirty-six hours. There may be slight lachrymation and the eyelids may be gummed together when the patient awakes in the morning, but the discomfort is very slight. The positive reaction varies in degree from a moderate congestion of the caruncle and conjunctiva to marked edema of these structures with fibrinopurulent secretion and photophobia. The local reaction is apparently accompanied by no constitutional disturbance nor is the local tuberculous process influenced in any degree. Diseases of the eye contraindicate the employment of the test. For a more detailed description of the types in which the reaction may manifest itself the reader is referred to the paper of Smithies and Walker.<sup>2</sup>

A number of instances in which untoward results have followed the use of the test have been reported. These have varied from persistent conjunctivitis<sup>3</sup> to interstitial keratitis<sup>4</sup>; one instance of destruction of the eye has also been reported.<sup>5</sup> In the writer's cases there were but two instances of marked conjunctivitis (cases xx and xxiii); these persisted for from ten days to two weeks; one case of persistent phlyctenular conjunctivitis has been observed in a patient who underwent the test in the wards of the Presbyterian Hospital.

In most of the patients reported in this paper a one per cent. solution of tuberculin was used, but

in a few a solution of one-half per cent. strength was employed. The amount instilled in each instance was 0.025 c.c. which was measured in a graduated throttle pipette, this instrument being sterilized by boiling before use. The technique employed in the instillations was that described by Baldwin.<sup>6</sup>

It has been stated that the tuberculin solutions are not stable but the one per cent. solution used by the writer remained potent for at least two months. When not in use it was kept tightly corked at an ordinary temperature. The tuberculin employed was furnished to the Presbyterian Hospital by the Rockefeller Institute of New York city.

When this study was undertaken it was intended to embrace only patients suffering from or suspected of being subjects of pulmonary tuberculosis, but owing to the kindness and interest of Dr. Jerome Kingsbury, class head in dermatology at the Presbyterian Hospital, Out Patient Department, a number of dermatological cases became available, and the results obtained in these are incorporated in this report. Most of the patients tested were selected from those applying for treatment at the Presbyterian Hospital, Out Patient Department, but two are from the writer's private practice, and several of the dermatological cases are from the service of Dr. Kingsbury at the New York Skin and Cancer Hospital. In recording the results obtained the following scheme<sup>7</sup>, which is practically that of Baldwin, has been adopted: 0, No difference in either conjunctiva. +, Slight difference, especially in caruncle. ++, Distinct redness of caruncle and palpebral conjunctiva. ++, Distinct redness of palpebral and bulbar conjunctiva with lachrymation and formation of fibrin. +++, Edema of lids and photophobia (chemosis).

CASE I.—L. B., female, fourteen years of age. Clinical diagnosis: Pulmonary tuberculosis (second stage). Bacilli found in sputum. On January 31, 1908, one half per cent. tuberculin in right eye. Result, ++.

CASE II.—A. H., female, thirty-six years of age. Clinical diagnosis: Probable pulmonary tuberculosis, incipient. No bacilli found in sputum. In this patient the physical signs were hardly sufficient to assure the diagnosis, and it is in such cases, in the writer's opinion, that the ophthalmic test will find its greatest field of use in the diagnosis of pulmonary tuberculosis. April 1, 1908, one per cent. tuberculin in right eye. Result, 0. April 13, 1908, one per cent. tuberculin in left eye. Result, +.

CASE III.—E. R., female, twenty-two years of age. Clinical diagnosis: Pulmonary tuberculosis, first stage. No bacilli found in sputum. January 31, 1908, one half per cent. tuberculin in right eye. Result, 0. March 27, 1908, one per cent. tuberculin in right eye. Result, +.

CASE IV.—B. F., female, thirty years of age. Clinical diagnosis: Pulmonary tuberculosis, second stage. Bacilli found in sputum. February 7, 1908, one half per cent. tuberculin in right eye. Result, +.

CASE V.—F. McP., male, sixty years of age. Clinical diagnosis: Pulmonary tuberculosis, third stage; Bacilli found in sputum. April 10, 1908, one per cent. tuberculin in right eye. Result, +.

CASE VI.—L. U., male, forty years of age. Clinical diagnosis: Pulmonary tuberculosis, third stage; Potts' Disease. No bacilli found in sputum. March 11, 1908, one per cent. tuberculin in right eye. Result, 0. March 25, 1908, one per cent. tuberculin in right eye. Result, +.

CASE VII.—J. F., male, forty-one years of age. Clinical diagnosis: Pulmonary tuberculosis, second stage. Bacilli found in sputum. March 29, 1908, one per cent. tuberculin in right eye. Result, +.

CASE VIII.—G. H., male, thirty-four years of age. Clinical diagnosis: Pulmonary tuberculosis, quiescent. This patient applied at the dispensary some two years ago in the second stage of the disease; bacilli were present in his sputum. He has done well under treatment and has gained twenty pounds. The signs of his old lesion are still demonstrable. February 10, 1908, one half per cent. tuberculin in right eye. Result, +.

CASE IX.—J. R., male, forty-four years of age. Clinical diagnosis: Pulmonary tuberculosis. The history of this patient is very similar to that of Case VIII. Bacilli were formerly present in his sputum, but have now disappeared. March 20, 1908, one per cent. tuberculin in right eye. Result, O. April 10, 1908, one per cent. tuberculin in right eye. Result, +.

CASE X.—C. J., female, twenty. Clinical diagnosis: Pulmonary tuberculosis, incipient. This patient has been under the writer's care at intervals for about four years. During the summer of 1907 she underwent an attack of pleurisy with serous effusion; this was treated by means of thoracocentesis. Recovery took place, but the clinical symptoms since her pleurisy led to the belief that there was a tuberculous lesion in the lungs, although no very definite signs could be demonstrated, nor were tubercle bacilli found in the sputum. It is in such patients that the ophthalmic test will prove extremely useful if further experience shows that it is reliable. March 7, 1908, one per cent. tuberculin in right eye. Result, +.

CASE XI.—M. O'B., male. Clinical diagnosis: Bronchiectasis; pulmonary tuberculosis, third stage. Bacilli found in sputum. February 7, 1908, one half per cent. tuberculin in right eye. Result, O. February 18, 1908, one per cent. tuberculin in right eye. Result, O. March 14, 1908, one per cent. tuberculin in left eye. Result, O. April 4, 1908, one per cent. tuberculin in right eye. Result, +.

CASE XII.—M. L. M., female, forty-one years of age. Clinical diagnosis: Pulmonary tuberculosis, first stage; surgical kidney. March 5, 1908, one per cent. tuberculin in right eye. Reaction, +. This patient was referred to the writer by Dr. George B. Campbell. Her family history was tuberculous, and she had been suffering from a bladder disorder for twelve years. The urine contained pus, and three times during the past three years a tumor appeared just above the left groin. Each time the tumor disappeared suddenly, without, however, any associated sudden increase in the flow of urine. Physical examination revealed the presence of a small tuberculous infiltration in the right lung and of two palpable kidneys, the left larger than the right and tender. A diagnosis of pulmonary tuberculosis and left pyonephrosis, possibly tuberculous, was made. No tubercle bacilli were found in the urine. The patient was sent to the Presbyterian Hospital, where the diagnosis of surgical kidney was confirmed by cystoscopy and ureteral catheterization, the pus from the affected kidney containing *Bacilli coli* in pure culture. Subsequently nephrectomy was performed by Dr. Ellsworth Eliot, Jr. The patient made an uneventful recovery.

CASE XIII.—J. C., male, twenty-five years of age. Clinical diagnosis: Cerebral syphilis (?); tuberculous brain lesion (?). February 24, 1908, one per cent. tuberculin in right eye. Reaction, O. This patient was seen at the Manhattan Eye and Ear Hospital by the courtesy of Dr. Frank J. Parker. The facts that the symptoms rapidly disappeared under the administration of potassium iodide in large doses and that the ophthalmic reaction was negative would seem to rule out tuberculosis as a factor in the aetiology.

CASE XIV.—Female, twenty years of age. Clinical diagnosis: Probable incipient pulmonary tuberculosis. February 17, 1908, one per cent. tuberculin in right eye. Reaction, O. April 21, 1908, one per cent. tuberculin in left eye. Result, O.

CASE XV.—J. J., female, sixteen years of age. Clinical diagnosis: (chiefly on history): Possible incipient pulmonary tuberculosis. No bacilli found in sputum. February 14, 1908, one per cent. tuberculin in right eye. Reaction, O. March 14, 1908, one per cent. tuberculin in left eye. Result, O.

CASE XVI.—K. K., female, thirty-six years of age. (Control test: Clinical diagnosis: Lupus erythematosus.) March 17, 1908, one per cent. tuberculin in right eye. Reaction, O. April 21, 1908, one per cent. tuberculin in left eye. Result, O.

CASE XVII.—W. N., male, thirty-seven years of age. (Control test: Clinical diagnosis: Acute postleptospiral

cinoma of stomach. March 9, 1908, one per cent. tuberculin in right eye. Reaction, O.

CASE XVIII.—L. M., female, thirty-five years of age. Clinical diagnosis: Necrotic granuloma (folliclicis). No evidence of other tuberculous lesion. April 13, 1908, one per cent. tuberculin in right eye. Reaction, +.

CASE XIX.—R. G., female, twenty-three years of age. Clinical diagnosis: Necrotic granuloma (folliclicis). This patient, several years ago, suffered from an attack of erythema induratum (Bazin) and now has enlarged cervical glands, which probably are tuberculous. April 17, 1908, one per cent. tuberculin in right eye. Reaction, +.

CASE XX.—H. H., female, twenty years of age. Clinical diagnosis: Necrotic granuloma (folliclicis). No evidence of other tuberculous lesion. April 13, 1908, one per cent. tuberculin in right eye. Reaction, +.

CASE XXI.—N. M., female, fifteen years of age. Clinical diagnosis: Lupus vulgaris. No evidence of other tuberculous lesion except slight dulness and diminution of the breath sounds at the apex of the right lung. April 13, 1908, one per cent. tuberculin in right eye. Reaction, +.

CASE XXII.—B. M., female, thirty-three years of age. Clinical diagnosis: Lupus vulgaris. No evidence of other tuberculous lesion. March 26, 1908, one per cent. tuberculin in right eye. Reaction, +.

CASE XXIII.—G. M., male, thirty-one years of age. Clinical diagnosis: Lupus vulgaris. No evidence of other tuberculous lesion. February 18, 1908, one per cent. tuberculin in right eye. Reaction, +.

CASE XXIV.—K. K., female, thirty-six years of age. Clinical diagnosis: Lupus erythematosus. No evidence of tuberculous lesion. February 28, 1908, one per cent. tuberculin in right eye. Reaction, O. April 20, 1908, one per cent. tuberculin in left eye. Reaction, O.

CASE XXV.—E. G., male, twenty-six years of age. Clinical diagnosis: Lepra. No evidence of any tuberculous lesion. April 17, 1908, one per cent. tuberculin in right eye. Reaction, O. April 23, 1908, one per cent. tuberculin in left eye. Reaction, O. This patient was tested as a matter of interest, since it is known that in leprosy injections of tuberculin under the skin may be followed by a constitutional reaction.

Since the ophthalmic test may be positive in typhoid fever it may be well to state that none of the patients who exhibited a positive reaction had suffered from a recent attack of this disease.

**Summary.** In summarizing the results it seems best to deal with the dermatological cases separately. Of the other patients, all those in whom the diagnosis was assured, either by the presence of distinct physical signs or by the demonstration of the presence of the tubercle bacillus in the sputum, a positive reaction was obtained, although in some instances two or more trials were necessary. The two patients (Cases XIV and XV) in whom a tentative diagnosis of pulmonary tuberculosis was made reacted negatively; the control cases (XVI and XVII) also gave negative results.

Of the dermatological cases, in all these, six in number, in whom the affection was one of tuberculous nature—for while necrotic granuloma is not of itself a tuberculous lesion according to the dermatologists, it seems to bear a constant relation to tuberculosis—an undoubted positive reaction was obtained, while, in the case of erythematous lupus (XXIV) the reaction was negative.

**Conclusions:** If one can deduce conclusions of value from the results obtained in an few cases it would seem that the following might be said:

The ophthalmic test is an aid of some value in the diagnosis of tuberculous conditions of the lungs, but in many instances is unnecessary since the diagnosis may be secured by the examination of the sputum and by physical examination of the chest. However, in incipient cases with equivocal signs the test may be of distinct assistance (provided

its results can be relied upon. Whether reliance is to be placed upon it or not further study of the reaction will show.

2. In lupus vulgaris and tuberculides of the type of necrotic granuloma (follicles) the ophthalmic reaction seems to afford a very material help in the diagnosis of the condition.

The writer wishes to express his sincere thanks to Dr. F. P. Kinnicut, attending physician to the Presbyterian Hospital; to Dr. E. F. DuBois, of the interne staff of the hospital; to Dr. F. J. Parker, ophthalmologist; and to Dr. Jerome Kingsbury, dermatologist to the dispensary, as well as to his other associates of the dispensary staff, whose aid and interest have made possible the writing of this paper.

## MERCURY AND TUBERCULOSIS.

BY WILLIAM F. BERNART, M. D.,  
Chicago, Ill.

The editorial in the May 22d issue of the *New York Medical Journal* on Mercury in the Treatment of Consumption, based upon the experiments of B. L. Wright, Surgeon, U. S. N., and published in the *U. S. Naval Medical Bulletin*, has assisted in advancing a topic of considerable interest, and magnitude. I say advancing, as the subject has been generally dealt with in articles upon the action of mercury, in which it is usually stated that this metal is contraindicated in certain wasting diseases, of which tuberculosis is one. It is barely possible that such deductions, in at least some varieties of tuberculous infections, were prompted by a faulty administration of the drug.

There is but little doubt that mercury administered so as to gain an intensive action without the production of toxic symptoms exerts a beneficial influence over some varieties of tuberculous infections; just what conditions are the most favorably influenced remain to be decided. It has been my practice for some years to use mercury intravenously for the routine treatment of syphilis, so possibly I can add a mite to an interesting subject. A survey of my statistics some months ago (preparatory to the publishing of an article on syphilis, not tuberculosis) showed that I had treated 422 syphilitics by the intravenous method, and had given 9,838 injections, of which 9,446 were of mercuric chloride, 327 of mercuric cyanide, thirty-two of sublimine (ethylenediamine mercury sulphate), and thirty-three of mercuric iodide. The average dose of mercuric chloride was 0.02 gramme ( $\frac{1}{2}$  grain).

Among the 327 patients treated with mercuric chloride were several with tuberculosis and from whom general observations were made. These observations at the time were not made for specific publication, as they apparently were foreign to my subject in view, but the rehabilitation of the topic of mercury in tuberculosis prompts this informal report.

Before citing the influence of mercury injections upon the tuberculous cases it might be of advantage to show that mercury, when given by injections, possesses certain actions exclusive of its antisypilitic ones; this especially applies to the mercuric chloride.

This drug when injected in full doses has a decided antithermic action in nearly all cases where the fever is the result of some germ invasion. Besides this, it also exerts what might be termed a sedative influence, that is, it decreases the nervous tension, or, as the patient expresses it, it makes him lazy and indolent. This latter action might be the result of a mild metallic poisoning. In view of this, it is not at all surprising that certain tuberculous patients at first seem to be favorably influenced by this method of treatment.

The general observations made on the syphilitic tuberculous patients of this series were as follows:

1. That the control of the active syphilis in many of the tuberculous patients seemed for the time to benefit the tuberculosis also.

2. That in patients with pulmonary tuberculosis, after the first control of the syphilis and if the treatment was continuously pushed, a few months would show a gradual aggravation of the tuberculosis.

3. That the genitourinary tuberculous patients, outside of the benefit to their syphilis, showed no improvement in their tuberculosis.

4. That two patients with tuberculous eye trouble were benefited, one markedly so and the other but moderately so. This is not surprising, as the intravenous injections of mercuric chloride exert a decided and beneficial influence over infections and ulcerations of the eye.

5. That the patients with pulmonary tuberculosis, evidently suffering from the absorption of septic materials, probably due to a secondary germ infection, were decidedly benefited up to a certain point, after which, if the mercurial treatment was continued, their retrogression was rapid.

Regarding the sending of tuberculous patients, as suggested editorially, to the various spas, such as Hot Springs, Ark., for the reason that they can probably tolerate larger doses of mercury there than elsewhere, I can only say that after five years of practice at that same resort I became imbued with the general impression in vogue, and this impression undoubtedly emanated from experience that, so far as the tuberculosis is concerned, syphilitic tuberculous patients do not do well under the treatment at that place. This impression may not be due to the use of mercury, but to the overdosing with the iodides, a habit nearly universally prevalent at the Springs.

42 MADISON STREET.

## PUERTO RICO AS A FIELD FOR RESEARCH IN TROPICAL MEDICINE.\*

BY BAILEY K. ASHFORD, M. D., U. S. Army,  
Washington, D. C.,

Honorary Member, Puerto Rico Anemia Commission.

(Under the Imprimatur of the Society of Tropical Medicine.)

There are a few remarks which may be made concerning certain diseases classed as "tropical" to be found in the island of Puerto Rico which may, perhaps, interest the members of this society in a nearby and very inviting field of study.

I was for some years in a position to see a large number of current dispensary cases as well as to follow up some special cases in the hospital. Prob-

\*Read at the fifth annual meeting of the American Society of Tropical Medicine, held in Baltimore, March 28, 1908.

ably about 15,000 were thus personally seen, and fully 20,000 more were observed by colleagues working similarly in other parts of the island. These patients represent fairly the average clinic among the Puerto Rican laboring class, numerically large, as it constitutes the vast majority of the inhabitants of the country.

The society will, perhaps, be able to reach some conclusion concerning the value of Puerto Rico as a point of observation of some, at least, of the affections more or less foreign to our temperate zone.

*Uncinariasis.*—This is without doubt the most serious of all diseases in Puerto Rico, not only in point of numbers infected, but also in morbidity and mortality. It is not probable that in any other country it is really the leading affection. Its characteristics are well known, and no extended comment is necessary, save to remind you that it is estimated that not far from 800,000 of its 1,000,000 of population harbored this parasite at the beginning of the American domination, and that from 5,000 to 7,000 died annually from its effects. Despite the approximate 150,000 to 175,000 persons treated by the Puerto Rico Anemia Commission it still remains the distinguishing feature of Puerto Rican pathology, although now clearly understood and properly treated by practically all insular physicians. Although what has been elucidated by divers authors is common knowledge, there is no point at which profound anemias and their effects can be better observed. Despite faithful attempts, no adequate explanation has yet been given of just how this anemia is brought about. Many believe that it is a hæmolytic due to some product of the worm. This remains to be established by actual proof, and constitutes a scientific problem of great interest which can possibly be best worked out in this island.

*Microfilaria nocturna.*—This parasite is commonly encountered. Twelve per cent. of the second battalion of the Puerto Rican provisional regiment of infantry, stationed at Cayey, were found to be hosts of this parasite, and while nearly all the infected were apparently healthy men, their military medical histories displayed from time to time the capacity of this worm of evil. Whether this is a fair proportion of infected among the civil population is problematical. Suffice it to say that filariasis was frequently seen among our patients in Ponce, and chyluria, varicose groin glands, lymph scrotum, and other manifestations were constantly in evidence. Many were also found who suffered no symptoms. Cases of elephantiasis were by no means in proportion to the number of persons in whose blood microfilariæ were circulating.

One of the most interesting phases of the disease is the so called "erisipela" or erysipelas. This is a most common condition and seems to bear relation to filarial disease, in most instances, when affecting a lower extremity without other apparent cause. It was our custom to suspect such cases of filarial infection, and a search through the blood at night was often rewarded by finding the elusive worm. This "erisipela" is, of course, a complication with the usual sharp reaction of a lymphangitis and is not at all fatal, as a rule, although I have

seen it result in death; it is apt to end in elephantoid swellings of the limbs, if not in elephantiasis.

As will be seen from the remarks on this, as well as on the succeeding diseases, we were unable to give our time to a thorough study of these cases as uncinariasis was claiming most of our attention. There seems to be, however, a decided tendency for lymphangitis of the lower extremity to recur again and again in filarial infections. Can there be a reduced resistance to the invasion of the streptococcus and other pyogenic organisms? Our experience with the affection would seem to indicate it. It is needless to say that filariasis could be made a most absorbing, perhaps very profitable study in the interest of the large number of persons of all stations of life who are victims of the disease, for it is not alone confined to the poor. It is certainly much more common in the mosquito plagued coast regions than in the highlands of the interior, as may be imagined, and is not rarely confounded with malaria if the indispensable microscope is not called into service. This is especially true in those cases where the chill, high fever, and sweat are all the symptoms to be elicited, a not uncommon picture in filariasis.

Other varieties of microfilariæ were not observed, although from reports from neighboring islands it is not unreasonable to suppose that they are to be found.

*Bilharziosis.*—This is not at all infrequent, the first announcement of the disease in Puerto Rico having been made by Gonzalez Martinez to the Puerto Rican Medical Association early in 1904. Thirty cases were disclosed in the routine examination of the feces of uncinaria patients by the commission, but these were not all that were seen by me. Others have made reports on bilharzia disease in the island, notably Gonzalez Martinez, of Mayaguez, who tells me that in 5 per cent. at least of the rural population of his district the eggs can be demonstrated in the feces. Great interest attaches to this affection because of its exclusive limitation to the rectal mucous membrane. It is due, almost certainly, to the *Schistosoma mansoni* of recent description and is not *Schistosoma hamatobium* as first believed.

Members of the commission repeatedly asserted their belief, based on the appearance of the ovum, that it was not identical with previously described schistosomata. Ova have never been found, to my knowledge, in the urine; the parasites were large, oval, and always provided with lateral spine. Apparently no symptoms are usually elicited, but that it can give rise to a serious affection is seen in the death of one of our patients, a child of twelve, in whom it was at least a contributory cause. During the long stay of this child in our field hospital, the infection was evidenced clinically by successive proctitis and prolapsus recti, and the autopsy revealed many adult worms in the splenic and portal veins. The worms and tissues were unfortunately damaged in preserving by an assistant. Examination showed that the parasite was *Schistosoma mansoni*.

The presence of the worm in Puerto Rico is believed by Stiles to consist in a continuous source to the island, a view borne out by the fact that cases of bilharziosis are apparently increasing in numbers.

At one point, Mayaguez, the infection seems to be deeply rooted in endemic form. Opportunities for infection are never lacking among a large proportion of the population, as the people go barefoot, and there are no features of successful invasion to alarm a patient, until extensive changes are wrought and widespread dissemination of the ova has been accomplished.

As a rule, the effects are simply those of the local manifestation which, in aggravated form, with bloody and mucous stools, tenesmus, and pain, sorely tax the patience and strength of the host. No high eosinophilia has been observed by us. Indeed we question the eosinophilia of bilharziosis, but a fair test of many cases has not as yet been presented, as it is so very difficult to find a patient suffering from the disease, who is not at the same time the host of *Necator americanus*, a potent cause, as is well known, of a eosinophilia, even, for a considerable period after expulsion of all worms.

*Ascaris lumbricoides*.—This is a very common parasite of man in the island and is mentioned merely because it is so extremely frequent.

*Oxyuris vermicularis* is common. In connection with this worm, we stumbled upon what may be a valuable point in its treatment: As is known, the use every day or two of rectal enemas of salt and water, infusion of quassia, etc., for four to six weeks is recommended to effect a cure, as the female resides in the cæcum and only goes to the rectum after her eggs have matured, where, of course, she would be reached by the remedies above mentioned. In one of our cases 418 oxyurides were expelled, all the patient harbored, by two doses of betanaphthol of two grammes each; the second dose was administered one week after the first. This is a simpler and prompter method of treatment than the old one.

*Strongyloides stercoralis* is not infrequent.

*Tricocephalus trichiuris* is very common, but, while rebellious to anthelmintics, large numbers have been expelled by thymol and beta naphthol, in spite of statements in medical literature, to the effect that they are insusceptible to its action. This worm may not usually cause anæmia, but we have seen cases in which it seemed to have done so. It occasions a moderate eosinophilia.

*Trichinelliasis* was never seen.

*Filaria medinensis* was not observed, and no evidence of its ever having been seen on the island can be obtained.

*Cestodes* are not at all frequent, and although *H. nana* was especially looked for it was not found.

*Trematodes* offer a fertile field for original work. Stiles reports in Osler's *Modern Medicine* upon a fasciola, sent him from one of the cases of the Anæmia Commission, and states that it is a new species. I have still another from another case found in Aibonito which is under consideration. *Paragonimus Westermanni* cannot be frequent if it exists in Puerto Rico. For several years I have searched for it, as have others, and as yet without result.

#### PROTOZOAN DISEASES.

*Amæbic dysentery* is not common, relatively speaking. Indirect testimony as to this statement

may be offered in the well known fact that abscess of the liver is exceedingly rare. I saw but one case while in Puerto Rico. A few cases of pathogenic amebæ were demonstrated in dysenteric stools.

*Trypanosomiasis* does not exist in the island.

*Trepanema pertenue* must exist, although I have not seen it personally. There is clear and undisputed evidence of epidemic yaws, occurring in at least two districts some twenty years ago. It was typical from the description given by many who witnessed the cases, and it is not unreasonable to suppose that it will come to the fore again.

All care and diligence has failed to reveal kala azar and, while the suspicious of some workers must be respected, I have to record that all evidence is as yet utterly insufficient to warrant serious attention. Of the hæmosporidia only the *plasmodia* claim attention. Statements concerning malaria in Puerto Rico must be accepted with great reserve.

Positive evidence can be offered for certain valleys and for some coast districts. A remarkable feature of such foci, as were uncovered by the Puerto Rico Anæmia Commission, is the limitation of separate species to separate districts topographically distinct. For instance, while working in Aibonito with a district of about 8,500 population, about 4,000 came under our care for uncinariasis. It soon developed that in the large tobacco plantations of the valley of the river Plata, there was a focus where practically all cases were quartans, on the other side of us in another punch bowl valley, tertian prevailed, while from the sugar plantations of Aguirre nearly all cases which reached us were estivoautumnal. Thus within a few miles, in any one of three directions, we could enter three distinct foci, each populated by mosquitoes, bearing in one *Plasmodium vivax*, in another *Plasmodium malariae*, and in a third *Plasmodium immutatum*. This curious condition may, and probably does, obtain in other parts of the island, but the well known fact that there is, as in the early days of Greece, comparatively little migration of peasantry from one to another natural division of land will in part explain this curious distribution.

#### BACILLARY DISEASES.

*Typhoid fever*, while not a tropical disease, is apparently influenced by its tropical habitat. It is very fatal, and Manson's statement that it is twice as fatal in India among Europeans, as in the home country, can be applied not only to continentals but to Puerto Ricans in the island under consideration. This disease is gradually becoming a cause of alarm, and while it existed sporadically before, its rapid strides since our occupation are causing universal comment. Recently I am informed that the large town of Caguas has been visited by a severe epidemic. One such epidemic was observed in Cayey, a mountain town of the interior, and one in Coamo; later a similar one invaded the town of Aibonito, where the commission was working, but it did not reach serious proportions as in the other towns mentioned. Our observation led us to the conclusion that these outbreaks were often by contact infection.

A rich opportunity for the application of antityphoid vaccines is here presented, at a critical period,

when such aid might be truly appreciated. It would be the only feasible way to put an end to what is already seemingly a serious condition, should the prophylactic value of the vaccine be established.

*Bacillary dysentery*.—At present the disease is not epidemic, nor was it during the existence of the Puerto Rico Anæmia Commission. We were informed that most severe epidemics are wont to fall upon the island at times. It seems to be the prevailing form of dysentery in Puerto Rico, and its character has been studied and reported upon by American investigators.

*Plague* has never been reported.

*Cholera* visited the island, during our own epidemic in this country.

*Leprosy* is not a common disease, but there is a colony at San Juan of perhaps fifty patients. I saw one case, suspected of this disease in Ponce by its health officer, in consultation with Dr. Joseph Goldberger, U. S. Public Health and Marine Hospital Service. This patient, whose nature was promptly revealed by scrapings from an incision into the anæsthetic lobe of the ear, was in hiding, and it is not improbable that there may be others of a similar nature, but such were not seen by any members of the commission. It may be of interest to know that all or nearly all cases are in native Puerto Ricans.

*Yellow Fever*.—Since the advent of the Americans, yellow fever, which, in the seven years preceding our arrival, gave an annual mortality of 161, has not been seen. *Stegomyia fasciata* are very abundant, however, and yet, in spite of this fact, there is much to confirm the general boast among the Puerto Ricans that the disease never really became endemic as in Cuba. Cases developed in certain towns open to commerce from that country and other infected posts, and usually in them only, but soon died out to be revived by fresh importations.

*Glanders*.—Several cases of glanders have been seen, and it has been not infrequent in horses, whose care is very poor.

*Tetanus* has been another serious question as a cause of infant mortality, but the responsibility for this state of affairs cannot be laid at the door of insular physicians. Dr. Francisco del Valle Atilas states, in an interesting thesis on the Puerto Rican peasant, in 1899: "... but of all diseases that an infant contracts shortly after birth, tetanus causes a higher mortality than any other. It can be said that the affection is endemic in Puerto Rico." I saw several true cases, and have heard of a large number of others, but the rate of 3.41 per cent. of the total mortality, given for the first seven months of our occupation of the island, and said to be about that for the ten years preceding, is certainly not due to the bacillus of tetanus. Many convulsions of infancy are wrongly attributed to it and so swell the reported mortality. It is, however, not at all uncommon even among adults.

*Tuberculosis* cannot be discussed here, but its ravages in towns are as great as its rarity among the people of the mountains.

#### OTHER DISEASES

*Beriberi* is not a disease of Puerto Rico. It has been described in the island, but the reasonable

doubt that uncinariasis was the true affection cannot be overcome, in the absence of examination of the faeces. The genuine danger of confounding certain cases of uncinariasis with beriberi is not to be lightly passed over. Of course, they are separated clinically in the vast majority of cases, but I have in mind now a case which would puzzle anyone without close study and, especially, in absence of a report on the examination of the faeces.

*Sprue* is not very rare; it occurs in foreigners to the soil and in some Puerto Ricans.

*Malta Fevers*.—Very careful search for Malta fever was made during several years but none was found.

*Pellagra*.—The writer has seen one case which appeared to be genuine pellagra.

*Heat stroke* is indeed rare, as Puerto Rico can hardly be considered a very hot country. This leads to the suggestion that the climatic effects of the tropics on our race be studied in this island. Even at high altitudes where it is cool and pleasant practically all of the time, "tropical neurasthenia" is in evidence. The nervous system certainly suffers in a manner not yet clearly worked out, where heat cannot be considered a potent factor.

I believe, that this climatic effect is not alone seen in strangers unaccustomed to this latitude. *Mal de pelea, ataques, mal de corazon* are popular names for a very common nervous manifestation which is really hysteria. This is the nearest approach to a true brain storm I have ever witnessed. It is frequently among some women of the poorer classes, and its name, "the fighting disease," is not belied, as anyone who has seen it can testify.

The subject is not exhausted, but nothing has been said about certain fevers which after some study do not fit into any classification, simply because they have probably not been sufficiently studied. There is room for some valuable original work, to clear up such as are still an enigma to many painstaking men in the island.

This rapid review of the tropical diseases of Puerto Rico will indicate the importance of this country as a centre for research. A few words may not be amiss concerning the facilities for such investigations.

In the past few years a great change has been noticed in the attitude of the people with regard to problems of hygiene. The eradication of smallpox and yellow fever, and the attack on the prevalent and dreaded anæmia, have had their effect in deepening respect for the advance of modern preventive medicine. There is truly a remarkable faith in all that tends to combat disease with scientific weapons, and this among the most lowly class. On the other hand physicians have been brought to a full realization of their power, when efficient means are taken to diagnose by methods which include judicious use of microscope and approved instruments of recent adoption, to treat cases, not at all inclined to be relegated to proper obscurity, and use reasonable drugs, which do little harm, and also the conscience with appropriate care of all symptoms. These physicians are generally graduates of foreign schools, and their general knowledge has been often acquired at some of the most

famous European centres. Many of the recent graduates come equipped from excellent schools, both here and abroad, and have well supplemented the conservatism of practitioners, whose experience is of greatest value, by advanced ideas of medical thought and technique. The Puerto Rican Medical Association is a body of whom the island has reason to feel satisfied, and their tolerance and their desire for investigation of the problems affecting the health of their country are marked and worthy of the highest respect.

In such an island, isolated from extraneous influence, no better opportunity can present itself to demonstrate how modern conceptions of communicable disease can influence the health of a tropical country; and it is all the more of importance, when America can point to such satisfactory results in one of her new territorial acquisitions, in a group of islands, famous for years as points from which our knowledge of tropical pathology has been greatly enriched. We are, as it were, in competition with other powerful nations in the Antilles and we must "make good."

Scientific working parties may gradually develop a valuable centre for research. Puerto Rico offers special advantages for the undertaking of such a labor. It is a small island, densely populated with about 260 inhabitants to the square mile; 90 per cent. of its population can be classed as rural; it has good roads; and is within four or five days of New York by good steamers; it has a most beautiful and varied picture of mountain, valley, and level coast, and comfortable accommodations, and the ever attractive environment of new customs and people.

Laboratory facilities are to be had, but there is no large laboratory. The board of health has been very generous in the past, and aids scientific work in every possible manner. Besides this several physicians have at heavy personal cost developed small laboratories.

It is hoped that interest in this island may be aroused among the scientific men of our country, and, through this society, may make an effort to draw up some organized plan for coming into closer touch with the workers in this promising field for research.

#### ACUTE SYPHILITIC NEPHRITIS.

*With Report of a Case.*

BY JOHN BALLAGI, M. D.,  
Homestead, Pa.

No part, organ, or tissue of the human body is exempt from the ravages of syphilis. So there is no reason to doubt the existence of syphilitic nephritis, acute or chronic, just as we grant the existence of scarlatinal, malarial, alcoholic, etc., nephritides. The difference is that the former seems to occur rather seldom. According to Bamberger's statistics, quoted by Fischer (1), out of fifty cases of nephritis in luetic persons, syphilis as an ætiological factor could be accepted by four only. Prager (2) complains that his cases are not convincing, because the patients were exposed to other causes too, first of all, to the effect of mercury. That is why so many

are inclined to place the responsibility on mercury and not on syphilis.

Newer textbooks on syphilology do not give much enlightenment about the question, either. I just cite, for example, that of the late Robert W. Taylor. He says, in his excellent textbook (3), under the heading Albuminuria and Ephemeral Nephritis: "There can no longer be a doubt that early and sometimes rather late in the secondary stage, a mild or more severe form of nephritis may occur. . . . It is a glomerulonephritis, comparable to that of scarlatina. Some authors claim that mercurial treatment causes the kidney changes, but we have no definite knowledge on the subject" (italics mine). Osler (4), talking of the ætiology of acute nephritides, enumerates scarlet fever, typhoid, etc., as direct possible causes. But regarding syphilis he says only: "Acute nephritis may be associated with syphilis." Leube does not mention syphilis at all.

An editorial of this journal (5) bearing the title The Dangerous Action of Mercury on the Kidneys is practically discussing the same question, namely, whether nephritides occurring together with lues are caused by the syphilitic virus or by mercury? Admitting that "there certainly exists a syphilitic nephritis in both the secondary and tertiary period," on the whole, the uncertain nature of this "syphilitic nephritis" is plainly expressed through the caution with which it is recommended to give mercury to syphilitic patients with albuminuria. The main points are also given how to distinguish and enable oneself to know when mercury is indicated and when it is dangerous. Among these diagnostic points I missed just one, but one which in many cases could do much more to enlighten the situation than anything else. That is a trustworthy history of the case. A patient with chronic nephritis, having acquired syphilis later, is hardly a fit subject to a protracted mercurial treatment. But when it is possible to decide with certainty that syphilitic infection occurred *before* the appearing of any symptoms of nephritis, and that the patient did not take any mercury at all, then we are justified to suspect the nephritis to be of luetic origin, and we would not make a mistake in introducing a mercurial treatment. When no history is obtainable, chemical analysis of the urine, saliva, blood, etc., may decide the question. Mercury can be detected in the organism months after it was incorporated, and with so much more certainty when recent mercurial poisoning—that is, mercurial nephritis—is present.

According to the same editorial, kidney changes due to syphilis or mercury may be slight. Other authors, too, speak simply of "syphilitic albuminuria." Plain albuminuria, I suppose, is not equal to nephritis. Plain albuminurias, due either to lues or mercury, may be more common and easily avoid our attention. Real syphilitic nephritis is rather seldom met with. Regarding these slight albuminurias, our knowledge is not sufficient at present to classify them either as luetic or mercurial. The kidneys are very sensitive to any toxic matter passing through them, and when they are exposed to several of them simultaneously, so much harder will it be to tell which is the guilty one.

Concerning mercury, I do not think its action on the kidneys is sufficiently cleared up. Mercurial poisoning (stomatitis) is a very common occurrence, so we ought to see more of its effects on the kidneys. But cases of mercurial nephritis are so rare as to be worth publishing. So does Wilson (6), reporting a case ending fatally after administering eighty-four grains of calomel in fourteen days. But his case is not instructive, the dose of mercury being far over the limit. Almost any kidney would be deranged when the patient was taking such enormous doses of any active drug. And what more, Wilson's patient was suffering with pericarditis and insufficiency of the mitral, aortic, and tricuspid valves, consequently with a very much impeded circulation and metabolism. Wilson's other cited cases would weigh more, too, if they were not examples of exceptional idiosyncrasy against mercury. What we need to know is whether regular doses of mercury are capable of exciting albuminuria or nephritis. As to my experience with syphilitic patients, I never had occasion to restrict or stop mercury on account of urinary troubles. Maybe some of my patients did have a slight albuminuria in the course of the disease, but the every day general practice is not the field where such cases can be easily detected if not accompanied by some special complaint or symptom.

The closing remarks made by Wilson I partly concur with. The first one is a good suggestion, that in every case when mercury is to be administered for a longer period, a careful uranalysis should be made. But when nephritis complicates an existing syphilis I am of a different opinion. I would "except those cases in which it is possible to trace the renal disability to a syphilitic infection." Then I think no one needs to be afraid to employ an energetic antisymphilitic cure with mercury, supposing that is otherwise indicated, too. What a good dose of mercury can do, the case I shall report clearly shows.

Much depends on the mode of administering and the preparations used. Internal administration and inunctions are more dangerous. Wilson and Heller prefer the injection of soluble salts, particularly the bichloride. So do I. The insoluble preparations—metallic mercury, mercury salicylate, calomel, etc.—are either too slowly working or their effect is apt to be cumulative. Gotthel (7) sets off as a great advantage of the insoluble salts the following: "By the injection of a dose of the insoluble compounds a medicinal depot, as it were, is established into the tissues." This sounds well, but is rather a disadvantage. We do not give drugs to remain in the body an incalculable and unlimited period. On the contrary, medicines, after having developed their specific action on the tissues, are expected to leave the organisms, the sooner the better. Winkler (8), of Stockholm, calls special attention to the danger of producing "depots" by injecting insoluble mercury in the tissues, and relates several cases from his practice, with very bad complications. He admits the relative harmlessness of the salicylate on account of its earlier elimination.

I would warn everybody against the injection of calomel or gray oil. In a paper read before the

Homestead Branch of the Allegheny County Medical Society in January, 1906, I reported a case from my own practice of a young woman who had eight such "medicinal depots" of calomel in her body. They did not trouble her until after the eighth injection, but then, all of a sudden, such toxic symptoms developed that all these depots had to be surgically removed to save her life. Fortunately, the injections were made in the muscles of the back. Since that time (it happened in 1894) I never used calomel for injections. With the corrosive (five per cent. solution) I never had any unpleasant experience.

The following case is very instructive in many respects. Its history is precise, the symptoms clear and distinct, the effect of the mercury so prompt and decisive that the whole might easily pass for an experiment in pharmacology:

CASE.—Michael G, thirty-five years old, a native of Hungary, mill worker, married, but living separated from his wife, she being in the old country. I used to know him for the last three years, attending to some minor accidents. He was of a healthy family, strongly built, broad shouldered, a man of temperate habits. The only sickness he had was smallpox when about three years old.

On March 5, 1906, he came to my office very sick, but with the sole complaint of an incessant cough and dyspnea about five or six days' standing. He was hardly able to walk. Upon examination, I found a general dropsy; the face puffed, lips cyanotic, moderate ascites, heavy anasarca of the under extremities and of the scrotum. The scrotal sac was as large as a child's head, the præputium hard and phimotic. Edema of both lungs with considerable dyspnea, and continuous cough, with thin, abundant sputum, mostly mucus. Percussion showed slight dullness on the bases, auscultation weak breath sounds, large and small moist râles. Heart sounds were feeble on account of the noisy râles, but clear. There was no detectable pleural effusion. Temperature was normal, pulse 100 and over, strong and full. Digestive organs were normal, upper limit of liver dullness was normal, spleen not palpable. He was passing very little urine lately and he could not pass any in my presence, but in a few hours he sent to my office about 40 cc. dirty brown looking fluid containing albumin, blood, epithelial, and blood casts. The daily amount did not reach more than about 300 cc.

On visiting him at his house the same evening I tried to get the previous history of his sickness. But he was not very communicative about it this time. Except that he noticed the swelling of his feet about eight days ago, he did not (or would not) remember anything. Anyhow, the uranalysis, together with the clinical symptoms, was more than enough to make the diagnosis of acute nephritis certain. I gave my orders accordingly: Rest in bed, milk diet, sweating procedures, and prescribed Hamman's James water in moderate quantities. To allay the distressing cough, I had to give a little opiate, in the form of Dover's powder, with quinine in small doses.

Before leaving, he asked me to look at and give medicine to some excoriations between the scrotal and perineal surfaces. He supposed they were caused by sweating and the continuous rubbing of the edematous skin. In fact, I myself expected to see a common erythema intertrigo. But instead of the reddened and chafed epidermis of erythema there were quite a number of moist, slightly elevated papules, some of them ulcerated, with a reddened areolar surface. Around the anus were quite a number of the same papules, some of them ulcerated, with a reddened areolar surface. I would have diagnosed this as a syphilitic eruption, but the finding of slightly enlarged glands in both groins gave some support to this and diagnosis.

On March 12, 1906, I visited Michael G. again. He was still in bed, but was able to get up and walk a few steps. The cough and dyspnea were still present, but not so severe. The face was still puffed, but the lips were no longer cyanotic. The ascites was still present, but not so marked. The edema of the under extremities and of the scrotum was still present, but not so marked. The scrotal sac was still as large as a child's head, but the præputium was no longer hard and phimotic. The edema of both lungs was still present, but not so marked. The auscultation was still weak, but the breath sounds were no longer so weak. The heart sounds were still feeble, but not so feeble. The temperature was still normal, but the pulse was no longer so strong and full. The digestive organs were still normal, but the upper limit of liver dullness was no longer normal. The spleen was still not palpable. He was still passing very little urine, but he was able to pass some in my presence. The daily amount was still about 300 cc.

Upon closer questioning he admitted to having indulged in extramarital coitus some seven to eight weeks before in a cheap dive. He never saw anything like a primary sore, but noticed a few weeks after the coitus a small hardening in the sulcus corone on the right side next to the frenulum. It did not hurt him, so he did not care much about it, so much the less because his prepuce was a little tight always and he was not able to push it back easily. I could not retract it either, but after compressing it and squeezing the serum out of the swollen prepuce the sclerosis still could be felt.

It was evident and plain enough that the patient was suffering, besides the acute parenchymatous nephritis, with active syphilis in the secondary stage. The question was, Did the syphilitic infection cause the nephritis, or was the presence of both merely accidental? Since the patient so forcibly and repeatedly asserted that the dropsy, urinary troubles, etc., came on rather suddenly and not more than eight days ago, since no other aetiological factor could be considered, I accepted the first alternative. Still, I hesitated a little to give mercury, in face of the very much lessened eliminative ability of the acutely diseased kidneys. I waited two days more, but seeing the patient's condition turning from bad to worse, I made up my mind and gave an injection of a five per cent. corrosive sublimate solution on March 8th. For local application to the ulcerations I used alcoholic solution of corrosive sublimate and dusting with boric acid. Frequent rinsing of the mouth, hot packs to stimulate sweating, restricted, mostly liquid diet, etc., were ordered also.

The result of the injections was indeed very satisfactory. The fourth day after the first injection, March 12th, the amount of urine was doubled, the oedematous skin became softer, the dyspnoea and cough much easier. The sixth day he passed nearly 1,500 c.c. urine; there was much less albumin in it, no blood, and very few casts. Oedema and dyspnoea almost disappeared. The eighth day, March 16th, I gave another injection, and in a few days the mucous patches began to dry up. Urine was normal, quantity and quality, on March 21st, and he felt so much improved that he went to work. This happened without my consent, though; knowing my customer, I told him again and again the necessity of a prolonged treatment, and particularly that the attained improvement would be lasting in case only when he was to receive at least six to eight injections. Notwithstanding this advice, he failed to appear for a third injection, and went away to Beaver Falls, where he was promised a more lucrative job. He did not stay very long. After three weeks, in April, he came back again, very much scared, noticing the swelling of his feet and new patches in his mouth. This time he had more common sense, and patiently went through one series of injections and stayed under my care till January, 1908, when he returned to the old country, to his wife. No luetic symptoms were visible then. During this time, from May, 1906, to January, 1907, he was kept on progressing doses of potassium iodide with intervals of two weeks every other month. January, 1907, I administered four injections again, and after them prescribed potassium iodide again, now in constant doses of a gramme daily. He never showed symptoms of renal trouble any more since May, 1906. Before he left, I instructed him to consult a reliable physician in the old country upon arriving there.

## RESULTS OBTAINED FROM USE OF DIPHTHERIA ANTITOXINE REFINED AND CONCENTRATED BY GIBSON'S METHOD.

By ROBERT E. WODEHOUSE, M. D.,  
New York.

Member of the Toronto Academy of Medicine, Former Medical Superintendent, Isolation Hospital, Toronto; Former House Surgeon to Hospital for Sick Children, Toronto, etc.

The experience which I have had in the use of diphtheria antitoxine, both prophylactic and therapeutic, prompts this brief note:

The prophylactic experience was gained chiefly while house surgeon in the Hospital for Sick Children, Toronto, and in the Lake Side Home for Little Children, Toronto Island. The board of trustees, at the suggestion of Dr. William Goldie, visiting physician in charge of infectious diseases, issued a standing order that each patient, when admitted to either institution, must receive 1,000 units of diphtheria antitoxine, and 500 units every two weeks thereafter so long as the child remained. This routine, practised in a service embracing nearly 175 children under fourteen years of age, brought out all the good and bad features associated with the injection of antitoxine. The marked idiosyncrasies of some of the patients and absolute non-tolerance of others was evident. The injections were discontinued in three cases, one a rheumatoid arthritic case and two tuberculous hip cases. The numerous forms of skin rashes and the frequency of their occurrence were constantly before us; also the terror some of the smaller patients had for the second and succeeding injections. The antitoxine used was of the ordinary, nonconcentrated, entire serum form, running 500 units to the c.c.

In the baby ward, to overcome the pain associated with the distending of the tissues due to the injection, I used an antitoxine of a potency of 1,000 units to c.c. Only 0.25 of a c.c. was required to give each baby the necessary injection of 250 units. This small dose could be administered with an ordinary hypodermatic needle, almost without pain. This was actually proven in two cases where the injections were given in the buttocks without the knowledge of the child, partially overcoming one of the objectionable features in connection with the administration of the antitoxine. The troublesome urticaria and also erythema, resembling scarlatina, and sometimes measles, were not materially changed.

Upon the completion of my services in these institutions I accepted the appointment of medical superintendent of the Isolation Hospital, Toronto, tendered to me by Dr. Charles Sheard, medical health officer. At this time a refined and concentrated antitoxine, prepared after Gibson's method, was offered in Toronto. The antitoxine was concentrated to a potency of 1,500 units to the c.c., and this at once appealed to me as highly advantageous where large therapeutic doses of 15,000 units and upward were necessary, as in the Isolation Hospital. It was suggested that the intensity and frequency of skin rashes and urticarias were very much re-

<sup>1</sup>Dr. Robert B. Gibson, assistant to William H. Park, M. D., director of the Research Laboratories of New York City Department of Health, developed the work of Atkinson and found a method of concentrating and refining diphtheria antitoxine serum by the elimination of the nonantitoxic substances. See *Journal of Biological Chemistry*, 1, No. 1, and 3, January, 1906.

duced by the use of this form of antitoxine. A sample consignment was forwarded and tried. The therapeutic effect was naturally equal to the old form of antitoxine, as a unit of antitoxine is an international standard. With Dr. Sheard's permission we procured a supply of this refined and concentrated antitoxine, altogether 1,560,000 units, exclusive of the primary sample.

The following table shows how this antitoxine was used in 345 cases:

109 mild cases received a total of 591,500 units, average 5,500 units;  
96 moderate cases received a total of 721,000 units, average 7,500 units;  
37 severe cases received a total of 409,000 units, average 11,000 units;  
25 mixed (scarlet fever and diphtheria) cases received a total of 120,000 units, average 4,800 units;  
18 negative swab cases received a total of 71,000 units, average 3,933 units.

In addition to this list, some poor patients not admitted to the hospital received antitoxine on application of the attending physician. (A commendable practice was instituted by Dr. Sheard of providing antitoxine to the poor from the Isolation Hospital, whenever requested by a physician. In all, over 2,000,000 units were used in five months, 440,000 units of this being made up of whole serum of different makes, testing about 500 units to 1 c.c. When a patient received antitoxine the time, amount, kind, and the name of the administrator were recorded, also any systemic effects or skin rashes following its injection.

Of the 345 patients observed in the hospital, only four receiving refined and concentrated antitoxine developed an urticaria covering a larger area than ten centimetres in diameter, surrounding the point of injection. In two the affected area remained confined to the thigh and buttock. In one case the abdomen and extremities were involved. In the fourth case, one of the three most marked cases I have seen, diphtheria developed in the third week of scarlet fever. The patient—nine years old, very fat, having an appearance of slight degeneracy and also a status lymphaticus condition—was attacked with general oedema, very marked about the eyes, lips, and face. Urticaria was extreme and very itchy. Urine was suppressed, temperature above 103° F., and myalgia and stiffness in the joints of the extremities marked. Catharsis and calcium lactate treatment were instituted on the suggestion of Dr. Wilson, a private physician in charge of the case. The condition persisted four days. In several cases painful myalgia developed. This was also present with some degree of severity in two patients who received no antitoxine and in other cases receiving ordinarily prepared antitoxine.

With these exceptions no symptoms traceable to the use of refined serum were found, erythema being entirely absent. In the same wards, ordinary serum (products of three different manufacturers, using other than Gibson method of concentration) being used at the request of visiting physicians on private patients, produced the usual ten to thirty per cent. of cases showing erythematous and urticarial rashes.

Upon further investigation, to satisfy myself as to the possibility of our results being due to an

extra good lot of serum produced from one horse, we obtained from Dr. Lederle, in whose laboratories the antitoxine was prepared, the following facts:

96 vials (5,000 units each), received September 21, 1907, were laboratory No. 40.  
60 vials (5,000 units each), received November 16, 1907, were laboratory Nos. 42, 40, 41, and 61.  
60 vials (5,000 units each), received November 16, 1907, were laboratory No. 61.  
96 vials (5,000 units each), received January 2, 1908, were laboratory No. 61.  
Laboratory No. 40 represented antitoxine obtained from Horse N.  
Laboratory No. 47 represented antitoxine obtained from Horses N and A (mixture).  
Laboratory No. 13 represented antitoxine obtained from Horse A.  
Laboratory No. 61 represented antitoxine obtained from Horse N (later bleeding).

This shows serum from two different horses; serum from two horses mixed; and serum from a second bleeding of the first horse, at an interval of some weeks.

This would lead one to believe, as Dr. William H. Park, of the Research Laboratories of the New York City Department of Health has found to be the case,<sup>3</sup> that the Gibson method of refinement and concentration is the constant factor in the production of the better results.

My reasons for asking Dr. Sheard's permission to continue the use of this serum refined and concentrated by the Gibson method are:

1. In therapeutic use, often 10,000 to 15,000 units of antitoxine are indicated for one injection. If concentrated to a potency of 1,500 units to 1 c.c., 10 c.c. only are necessary for latter dose, whereas in using the old form of antitoxine, with a potency of 500 units to 1 c.c., the tissues are necessarily distended three times as much by the injection of 30 c.c.

2. The much smaller sized syringe and needle necessary were very potent factors in dealing with neurasthenic, frightened patients, who always see every detail.

3. The systemic affections were markedly reduced.

4. In a hospital where both diphtheria and scarlet fever are treated, the early recognition and isolation of scarlet fever or measles, developing in the diphtheria ward, is most important. When refined and concentrated antitoxine has been used, there is no necessity of retaining patients with erythematous rashes under observation for several days, as we know these rashes rarely follow its use, whereas under the old methods, using the unrefined horse serum, with its accompanying rashes, the early diagnosis was always doubtful.

*After the Abdominal Operations.* The distressing thirst after abdominal operations, where fluid in mouth causes vomiting, is less relieved by subcutaneous infusions of normal salt solutions; or by the insertion of a tube into the rectum connected with a bag of water, standing about two above the level of the patient's hips, allowing the injection of water, until the fluid will no longer be absorbed, at the rectum to be 40. The patient may in this manner receive small quantities of water for hours. *Lancet*, *Journal of Surgery*.

## Our Readers' Discussions.

### A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at frequent intervals. So far as they have been decided upon, the further questions are as follows:

LXXV. How do you treat cholera infantum? (Closed June 15, 1908.)

LXXVI. How do you treat acute articular rheumatism? (Answers due not later than July 15, 1908.)

LXXVII. How do you treat varicose ulcer? (Answers due not later than August 15, 1908.)

Whoever answers one of these questions in the manner most satisfactory to the editors and their advisors will receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but not required) that the answers be short; if practicable, no one answer to contain more than six hundred words.

All persons will be entitled to compete for the prize, whether subscribers or not. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish. All papers contributed become the property of the JOURNAL.

The prize of \$25 for the best essay submitted in answer to question LXXIV has been awarded to Dr. Henry C. Becker, of New York, whose article appears below.

### PRIZE QUESTION NO. LXXIV.

#### THE TREATMENT OF SUNSTROKE.

BY HENRY C. BECKER, M. D.,  
New York.

In a consideration of the treatment of insolation we take cognizance of two forms, the *hyperpyrexial*, where the temperature is the important point at issue, and the other where an exhaustion or prostration is the important feature; the latter variety, known as *heat exhaustion*, may be mild, moderate, or severe.

In the *hyperpyrexial form* the vital point in the treatment is the rapid reduction of the temperature; the prognosis is fair in direct proportion to the rapidity with which the temperature is reduced, and in inverse proportion to the length of time it has endured. In an emergency place the patient in the coolest and shadiest place available, loosen the clothing, and dash cold water over head and body; with better facilities to hand place the patient in a bathtub of cold water, adding to it pieces of ice; the extremities and body should be constantly and vigorously rubbed while thus immersed. In those favorable cases where the temperature falls it is accompanied by an improvement in the pulse and respiration, and a clearing of the mind; it is well then to take the temperature per rectum every fifteen minutes, and remove the patient from the cold bath when the thermometer registers 102° F. The temperature often falls 2° every fifteen minutes, and may keep on falling even when the patient is removed from the bath; to obviate a subnormal temperature and a collapse, it is well to observe this rule. When the patient has been removed from the cold bath there may be a rebound of the temperature four or five hours after, particularly in those cases whose temperature has been above 106° F. This can be controlled by cold packs or cold sponging. Cold water enemas are in-

effectual unless ice cold, when they become too dangerous for use, the patient being liable to go into collapse. Antipyretics should not be used as a routine method, although in the tropics the hypodermatic use of quinine is highly spoken of. If there is much struggling or delirium a hypodermatic injection of one fourth grain of morphine may be given. The sudden shock from the cold water may produce a tonic muscular spasm including the diaphragm; in these cases five minims of amyl nitrite as an inhalation with an increase in the temperature of the water employed in bathing along with artificial respiration, if necessary, will tend to overcome the spasm; keep up the artificial respiration half an hour if need be.

There is a strong tendency to congestion and œdema of the lungs; this condition should be met by dry cupping and hypodermatic injections of atropine and strychnine. Strong, robust, plethoric individuals with full bounding pulses require one fiftieth of a grain of nitroglycerin; leeches to the temples and behind the ears are also helpful. After the reduction of the temperature the bowels should be emptied with a stimulating enema.

The after treatment consists in keeping the patient in bed for several days on a light and easily digestible diet; there is often a subsequent intermittent fever lasting several days; this is best treated by means of cold sponging and tablespoonful doses of spirits of milderorus given every four hours. For the headache small doses of acetphenetidin with citrated caffeine may be given. Special attention should be given to the bowel and kidney functions; any resulting sequelæ should receive appropriate treatment and care.

In the treatment of *heat exhaustion* stimulants are primarily indicated, and in severe cases, to insure their certain and prompt effect, they should be given hypodermatically.

The slightest manifestation as headache, vertigo, and faintness should be heeded, and the patient immediately removed to some cool and shady room or place. A teaspoonful of aromatic spirits of ammonia in a glass of cold water will suffice in the milder form of cases; if somewhat feverish cold sponging with alcohol and water is indicated. It is in the more pronounced and severer forms of heat exhaustion that heroic means are often necessary to save life; when there is respiratory failure strychnine, 1-30 to 1-15 gr. is to be injected, oxygen gas and artificial respiration may be required and resorted to; in acute heart failure camphor, 1 gr. dissolved in sweet almond oil, 6 m.; or a solution of citrated caffeine, 1 to 2 grs., injected; if pulse is soft and feeble digitalin, 1/200 gr., repeated in an hour if necessary; if pulse is full and bounding, 1/100 to 1/50 gr. nitroglycerin. For reflexly stimulating the nerve centres mustard paste or the douche may be employed.

The after treatment is rest in bed, with tonic and stimulating medicines and treatment of any resulting sequelæ.

*Prophylaxis.* This consists in the prevention of exposure to the direct rays of the sun, moderation in the amount of physical and mental work, the wearing of light and cool clothing during a protracted spell of hot and humid weather. The diet

should consist of little meat with plenty of vegetables and fruit; strong alcoholic liquors should be eschewed. Water externally and internally so that bowels, kidneys, and skin may be kept active, for as a general rule a patient who sweats does not suffer sunstroke.

112 WEST ONE HUNDRED AND FOURTH STREET.

*Dr. B. B. Scarlett, of Philadelphia, says:*

The treatment of sunstroke by the writer consists in the removal of the patient to a shady spot, the loosening of the clothes, the application of cold to the head, and the administration of a stimulant hypodermatically, if necessary. When conditions permit more radical treatment, the patient should be stripped, covered with a sheet, placed in a tub of ice water with an ice cap to the head, and the body gently rubbed with a large piece of ice. The bath should be discontinued, and the patient put to bed when the temperature reaches  $104^{\circ}$  F.; for beyond this point the temperature usually continues downward on its own accord; whereas, if the patient is kept in the tub until  $99^{\circ}$  or  $100^{\circ}$  F. is reached the temperature will invariably become subnormal. The ice cap should be kept to the head until the patient has completely recovered from the attack.

If doubt exists as to the physical ability of the patient to stand the tubbing, the body should be covered with a sheet, upon which are placed small pieces of ice, while quantities are laid loosely about the head. Enemata of ice water of about a quart should be given every ten or fifteen minutes until the axillary temperature reaches  $102^{\circ}$  F. These injections not only assist in reducing the temperature, but they supply to the body fluid that has been lost by excessive sweating. The dashing of ice water upon the patient from a distance of five or ten feet often hurries the return of consciousness.

In cases where the temperature is not extreme, I simply wrap the patient in a large muslin sheet wrung out of cold water, and cover all with a blanket. As soon as the sheet becomes warm, it is to be replaced by another that has meanwhile been cooling in the water. This is continued until the temperature reaches normal. The depression in temperature by this method is not a rapid one, but there is seldom, if ever, a secondary rise.

In extreme cases where everything else has failed to restore the patient to consciousness, the most efficacious stimulant is the pouring, from an elevation, of a fine stream of ice water upon the forehead. As this treatment is very radical, it is continued for only one or two minutes at a time. In conjunction, a full dose of the tincture of digitalis should be given hypodermatically, except in plethoric patients, with great arterial tension. In such cases venesection should be practiced and should be followed by smaller doses of digitalis. The patient should be put to bed and warmly covered when the temperature reaches  $104^{\circ}$  F.

The sudden removal of coverings in infancy should be treated by covering the body with hydrocortisone and administering more water liberally. In the severe form, a bath, the temperature of which is not below  $95^{\circ}$  F., should be used. At the same time friction should be vigorously applied to keep the peripheral arteries dilated.

In all cases stimulants should be administered when indicated. Whiskey should be given by the bowel except in those cases where the patient was under its influence at the onset of the attack. Hypodermatic injections of ether, followed by caffeine, should be given in cases of collapse. Camphor and nitroglycerin are also useful drugs in emergency. Convulsions should be relieved by inhalations of chloroform. Venesection should be resorted to in cases of convulsions and much cyanosis, and should be free and copious. The bleeding should be followed by injections of salt solution. This provides for the loss of fluid during the days of sweating, dilutes the waste products in the blood, and is especially beneficial where the blood is thick and tarry.

After the reduction of the temperature the treatment should consist of light diet, fresh air, perhaps an ice cap to the head, and the administration of stimulants, if necessary.

To prevent subsequent attacks the patient should be advised to avoid, on hot days, violent exercise, beverages containing alcohol, and excesses in the use of animal foods.

*Dr. Alexander Rovins, of New York, remarks:*

Prophylaxis being of utmost importance I make it a rule with the advent of hot weather to instruct those of my patients whose occupations expose them to great heat, whether artificial or that of the rays of the sun, such as bakers, laundrymen, workers in sugar refineries, foundries, and the like, as well as drivers, peddlers, etc., especially if they are addicted to alcohol, or inclined to be plethoric or obese,—to avoid excess of any kind, particularly as regards spirits, to dress lightly, not to overload the stomach, especially with solid food, not to overwork,—in a word to “take things easy”; in addition to this drink plenty of cool water so as to perspire freely, bathe frequently, or at least sponge yourself with cool water twice or three times a day. I impress it upon them that heat stroke is especially liable to attack them during the hot, damp days, or while they work in an atmosphere surcharged with moisture, and that as long as they keep on sweating more or less profusely the danger of being “struck” is practically reduced to a minimum. The moment perspiration ceases, and they begin to feel uneasy, slight or throbbing headache, dizziness, etc., to give up the work at once, and seek rest and shelter in a cool and airy place. In an hour or so they may cautiously resume and continue their work. These instructions are simple and easily remembered, and as I find from experience, usually willingly carried out.

When called to a case of sunstroke under some of your diagnoses, and in lack of space for a very discussion of the distinctive diagnosis between this and other conditions that may simulate it, I will only mention some of the latter as seen in a case of venereal disease. I think some of the symptoms and signs of the latter may be the same as noted above, the most common being headache, vomiting, epistaxis, and some also the difference in amount between heat stroke and heat exhaustion, as the treatment of the latter condition is quite different from that of the former. Upon a careful study of the diagnosis you enter upon the treatment of sun

case, and that promptly and vigorously in one of more or less decided severity, with two aims in view: 1. The reduction of the temperature, and that as quickly as possible before tissue changes consequent on prolonged high temperature have resulted; 2. the stimulation of the nervous centres that have been overwhelmed by the high temperature.

For a mild case it may be sufficient to remove the patient from the noxious surroundings to a cool, well ventilated, airy place, loosen his clothing, and allow him to rest in a recumbent posture for a few hours, when he may be allowed to go home to take a prolonged rest of two to three days, and then cautiously return to his occupation. An attack of this kind may be followed by no deleterious results; but in some cases there is established in the individual an intolerance of heat, and a predisposition to heat stroke; and it often becomes advisable to warn such patients against even slight exposures to heat.

In the severe cases with flushed, hot, and dry skin, with pulse rapid and full (or quick and jerkin), complete or semiconsciousness, stertorous, sighing breathing, congested face and neck with throbbing carotids, etc., energetic treatment is called for. Remove patient to a cool, airy place, strip him of his clothing, and place him into a bath or bathtub of cold water which may still further be cooled by adding some ice to it. While in bath rub him vigorously, as this tends to reduce the congestion of the internal organs, and drives the blood therefrom to the surface of the body. If a bath is not at hand, place the patient on a mattress covered with a mackintosh or a piece of oilcloth, and rub him all over his body with lumps of ice. Dash cold water over him; enemata of ice water tend to reduce the temperature very decidedly, and so does an ice pack (sheets wrung out in ice cold water). An ice bag or cloths wrung out in ice cold water should be placed on the patient's head all the time. While thus treated the patient's temperature should be taken at short intervals (preferably by the rectum), and the hydratic treatment should be desisted from as soon as the thermometer registers 101° F., otherwise there is the danger of the temperature running down to the subnormal, thus placing the patient in the imminent danger of collapse. The patient is now made as comfortable as possible, cathartics are administered, and, if necessary, he is catheterized. Subsequent rises of temperature are controlled either by cool spongings, or, if the condition of the heart permits it, by the cautious administration of antipyretics (acetphenetidin, antipyrine, quinine). Convulsions accompanying an attack are controlled by hypodermatic injections of morphine (gr.  $\frac{1}{4}$ ), and inhalations of chloroform; 30 grains of sodium bromide and 20 grains of chloral hydrate injected into the rectum are also good for convulsions. If the circulation shows any signs of failing, a hypodermatic injection of strychnine, digitalin, or Hoffmann's anodyne will brace it up. This is especially to be looked for after the reduction of temperature, when symptoms of collapse and exhaustion that demand energetic stimulation may make their appearance.

Recovery is conditioned on absolute rest, removal

of all disturbing influences, a light and nourishing diet, regulation of the bowels, etc. Convalescence demands close attention, as intracranial mischief is apt to manifest itself at this period. This may vary from secondary meningitis down to increased irritability of temper. In addition to medication removal to a cooler climate and the strict regulation of the mode of living may conduce to making the patient as comfortable as possible under the circumstances.

*Dr. Albert Kaufman, of Wilkes-Barre, Pa., writes:*

In treating a case of heat stroke or sunstroke, we must bear in mind that this malady manifests itself in two forms: (1) the asphyxial or apoplectical form in which there is heat exhaustion, this form is rather of a rare occurrence; and (2) the hyperpyrexial form, or thermic fever, which is the most common form. The treatment, therefore, will differ in the two forms accordingly.

When the patient has thermic fever, the reduction of the high temperature is a vital indication,—the temperature usually being from 108° F. to 112° F., at which temperature life may be destroyed. The patient should be immediately removed to a cool, well ventilated room; his clothing should be loosened or removed entirely if possible. Place him upon a cot or bed, which is covered with a rubber sheet, so that the water may drain into a pail or trough. Ice should be used freely; an ice cap should be placed immediately upon his head, and an ice cold bath (ice floating in a tub of water) administered. Rub the surface of the body with ice in order to bring the hot blood to the cooled skin. Douching with ice water is very good, or an ice pack may be used advantageously.

The temperature should be taken very frequently by the rectum in order to watch carefully that the temperature does not fall beyond 100° F. If you should find such a fall in temperature, you should recognize this as a signal for the cessation of the ice applications, and the application of heat instead of ice may be called for. Great care should be taken in such cases, as collapse may threaten. Should the latter show any sign of existing, it may call for cardiac and respiratory stimulants, such as strychnine, digitalin, alcohol, camphor, ether, atropine, and nitroglycerin, hypodermatically, and in some cases artificial respiration must be resorted to; also the use of oxygen gas by inhalation is valuable.

If the pulse is bounding, the face cyanotic, and the heart laboring, it shows that the right heart is much dilated and venesection is to be resorted to, but this is to be used for this condition only, for if used indiscriminately, it does great harm.

In many cases asphyxia is a very troublesome and yet a dangerous complication, and it may be so urgent upon the life as to necessitate bleeding the patient. If venesection is used, you may at the same time also use subcutaneous or intravenous injection of normal salt solution.

If the temperature should still remain high, the application of ice and of the cold bath may be resorted to. Mustard may be applied over the præcordium, and if the temperature should go down below 100° F., it may call for heat in the form of hot water bottles, which should be applied to the lower extremities.

If the temperature regains its normal condition, let the patient remain quietly in bed. Give him cracked ice by mouth to settle the irritability of his stomach. Open his bowels with small doses of calomel. Food should be given of the most nutritious form and which is easily digestible, such as milk, buttermilk, and some very light broths. Keep him in bed for a few days until you are sure that it is safe for him to resume his duties, as in many cases there are dangerous complications and sequelæ, which may prove fatal.

A case of ordinary heat exhaustion does not require much skilled treatment beyond the removal of the patient to a cool and shady place. Loosen all his clothing, and take his temperature by rectum, as the thermometer is a sure guide in such cases, and you will find that it may be below normal, in which case you will have to use heat instead of ice applications as in the case of thermic fever. In order to restore the bodily temperature in this case you place the patient in a bath at 105° F. to 110° F., or use hot water bottles or hot bricks or hot packs. Such a case may call for cardiac and respiratory stimulants, such as the inhalation of ammonia, amyl nitrite, aromatic spirit of ammonia, or spirit of nitroglycerin by the mouth or hypodermatically.

If the heart is laboring hard and cyanosis shows and collapse threatens, lower his head, apply heat to his lower extremities, and give him a hot bath if convenient, and cardiac and respiratory stimulants by the mouth, by hypodermatic injection, and by inhalation as in any other case of collapse. Strychnine and digitalin may be used for a short time to combat the neuromuscular weakness.

The patient should be kept quiet and remain in bed and given highly nutritious food, including milk and broths. Open his bowels with small doses of calomel, and keep him in bed for a couple of days until he feels able to resume his duties.

*Dr. Joseph W. Walsh, of Brooklyn, N. Y., remarks:*

The successful treatment of sunstroke depends upon our ability to lower the temperature. The basis of the treatment should be the use of the cold bath. Place the patient in a dry sheet and lift him into a tub of water at a temperature of 80° F. and adding ice freely to lower the temperature of the water to its lowest possible point, using at the same time friction on the arms, legs, body, and head upon which you should simultaneously pour water at a temperature of 60° F. Before subjecting the patient to this treatment it will be helpful to give him spiritus frumenti, one ounce, and tincture of digitalis, m xx, fifteen minutes before the bath. As a rule following the bath we get a lowering of the temperature, a reduction of the pulse and respiration, and a refreshing sleep. The bath should last thirty to forty five minutes, depending upon its effect, when the patient may be lifted from the bath to a blanket and gently dried. The bath should be given in a warm room in which there are no currents of air blowing upon the patient. Ice water enemas in addition are effective in many cases, and the ice cap is indicated in all cases of sunstroke. The temperature should be frequently taken by mouth or rectum, and the treatment regulated by

the temperature index. We must remember that this treatment is powerful and capable if used too long of doing harm. Croton oil, three minims, may be given early with good effect in these cases, and a free state of the bowels maintained by the use of salines for some days after the absence of the fever. Should convulsions occur give morphine sulphate, gr. 1/4 to gr. 1/2, with or without atropine sulphate, gr. 1/100, by hypodermatic injection. If convulsions persist anesthetize patient, using chloroform, and if necessary keep the patient under the anæsthetic while giving the bath and watch the rectal temperature while so doing. The use of drugs to reduce the temperature is unwise, especially the more depressing coal tar antipyretics. The bath may be repeated every four hours if necessary, but with the temperature only moderately high, 101° F. to 103° F., the ice or alcohol bath should be repeated every two and one half hours. This will result in favorable symptoms which are:—A reduction in surface heat, a stronger pulse, a lessened axillary and rectal temperature, an increased depth of respirations, and a return of the conscious state. For heart failure strychnine sulphate, gr. 1/32 to gr. 1/20, every half hour; tincture of digitalis, m xx to m xxx, every half hour or hour; sparteine sulphate, gr. 1/2, every hour, all to be most judiciously used, until cardiac reaction is produced.

With the appearance of sthenic, apoplectic symptoms following the reduction of temperature or a condition of asphyxia presenting,—venesection should be seriously considered.

The sequelæ of sunstroke are headache, vertigo, insomnia, epilepsy, mental enfeeblement, monoplegia, paraplegia, and hemiplegia; and they should all be treated symptomatically.

*(To be continued.)*

## Correspondence.

### LETTER FROM OTTAWA.

*The Annual Meeting of the Canadian Medical Association.—The Question of an Official Journal.—The Canadian Medical Protective Association.—The Entertainments.*

OTTAWA, JUNE 25, 1908.

The forty-first annual meeting of the Canadian Medical Association, the first under the new constitution, was held at the Capitol, in Ottawa, on the 9th, 10th, and 11th of June, under the presidency of Dr. F. Montizambert, of Ottawa, director general of public health, Dr. George Elliott, of Toronto, acting as general secretary. The meeting was a pronounced success. It was amply demonstrated that sectional meetings were satisfactory and that, barring a few alterations, the new constitution provided for facilitating the work of the meeting. The scientific programme was of the first order, while the entertainments proved that the Ottawa men were not going to be ostentatious, and so had presented a "capital" programme. Dr. Risen Russell, of London, England, delivered the address in medicine. It was illustrated with lantern demonstrations, and dwelt upon the reflexes. The Surgical Rights of the Public was the title of the address in surgery, delivered by Dr. John C. Munro, of Bos-

ton. Dr. John B. Deaver, of Philadelphia, read a very favorably received paper on gallstones and gallbladder surgery. There was held a very interesting "symposium" on peritonitis. This was opened by Dr. C. W. Duval, of Montreal, with a paper entitled *The Bacteriology of the Peritoneal Cavity, with Special Regard to Peritonitis*. Dr. J. T. Fotheringham, of Toronto, followed, with a paper on the diagnosis and general medical treatment of the disease, stating that the malady really had no medical treatment, and that as soon as a physician found a case developing he should hand the patient over to the surgeon. The surgical treatment was dealt with in papers by Dr. J. F. W. Ross, of Toronto, who advocated closure of the wound without drainage, and by Dr. Murray MacLaren, of St. John, N. B., Dr. L. C. Prevost, of Ottawa, and Dr. George E. Armstrong, of Montreal. The special committee on the establishment of an official journal reported favorably on the project and asked that the Finance Committee be instructed to go on with the project. The Finance Committee, appointed by the Executive Council, were Dr. J. F. Fotheringham, of Toronto, convener; Dr. F. N. G. Starr, of Toronto; Dr. R. W. Powell, of Ottawa; Dr. George E. Armstrong, of Montreal, and Dr. James Bell, of Montreal. A special committee to be known as the Milk Commission of the Canadian Medical Association was appointed, with Dr. C. J. Hastings, of Toronto, as chairman, with members in every province of the Dominion. Dr. A. T. Shillington, of Ottawa, was appointed chairman of the Committee on Medical Legislation; Dr. R. A. Reeve, of Toronto, chairman of the Committee on Medical Education; Dr. C. J. Hastings, of Toronto, chairman of the Committee on Public Health; Dr. H. B. Small, of Ottawa, chairman of the Committee on Amendments to the Constitution and By-laws; Dr. F. A. L. Lockhart, of Montreal, chairman of the Committee on Reports of Officers; and Dr. J. H. Elliott, of Toronto, chairman of the Committee on Necrology. On motion of Dr. H. A. Bruce, of Toronto, Dr. Risien Russell, of London, England, Dr. John C. Munro, of Boston, and Dr. John B. Deaver, of Philadelphia, were elected honorary members. Winnipeg was decided upon as the place of meeting in 1909, with Dr. R. J. Blanchard as president, the presidents of the provincial medical societies as the vice-presidents, and the secretaries of the provincial medical societies as the local secretaries, with the exception of the province of Quebec, which has no provincial medical society. For that province Dr. F. A. L. Lockhart, of Montreal, was elected vice-president and Dr. C. A. Peters local secretary. Dr. George Elliott, of Toronto, was reelected general secretary and Dr. H. B. Small, treasurer.

Dr. R. W. Powell, of Ottawa, the president, occupied the chair at the seventh annual meeting of the Canadian Medical Protective Association, which was held in Ottawa on the 9th of June. He reported that since the association was organized, in Winnipeg, in 1901, not a single case which they had undertaken to defend had been lost; that the fact, becoming known among the public at large, that the medical men of Canada had at their back

an organization of this character was acting as a deterring influence against causeless litigation, and that year by year there were fewer cases than in the previous year which they had to defend. During the seven years the association has accumulated nearly three thousand dollars. The fee for membership is three dollars. Dr. Powell was reelected president and Dr. J. Fenton Argue, of Ottawa, secretary. The new dean of the Medical Department of McGill University, Montreal, Dr. Francis J. Shepherd, was present, and on every hand was receiving congratulations. Dr. Roddick, the retiring dean, was also present.

The entertainments took the form of a reception at the Ottawa Golf Club on the evening of the first day, an excursion to Caledonia Springs on the afternoon of the second day, and a smoking concert on the evening of the third day, besides numerous private functions. Sir Wilfrid Laurier, Canada's Prime Minister, and the mayor of Ottawa delivered addresses of welcome.

### Therapeutic Notes.

**Solvent for Uric Acid.**—Fiessanger (*Journal de médecine de Paris*, May 9th) prescribes the following powder to be taken as directed:

R	Dried sodium phosphate,	
	Sodium sulphate, .....	āā 3ss;
	Sodium bicarbonate, .....	gr. xlv.

M.

Dissolve the mixed powder in a quart of boiling water, and take one wineglassful in the morning on an empty stomach; half a wineglassful at 11 o'clock a. m., at 4 o'clock p. m., and on retiring for the night.

**Carminative Mixture in Flatulent Dyspepsia.**—A. F. Plicque (*Le Bulletin médical*, May 16, 1908) advises the use of the following mixture for the relief of the spasms of pain accompanying flatulent dyspepsia:

R	Oil of anise, .....	gtt. xl;
	Tincture of valerian, .....	3i;
	Tincture of opium, .....	xlvj;
	Magnesium carbonate, .....	3i to 3iiss;
	Peppermint water, .....	3iiss.

M. et Sig.: One teaspoonful every hour, or every half hour, until relieved.

**Diabetic Coma.**—After the withdrawal of a certain amount of blood in diabetic coma of acidemia it is advisable to inject into the veins solutions that approximate normal blood plasma rather than either physiological saline solution or saline solution with a large amount of sodium bicarbonate. The following is Ringer's solution, which may be used for this purpose:

R	Sodium chloride, .....	gr. cxxxvj;
	Calcium chloride, .....	gr. iv;
	Potassium chloride, .....	gr. viiss;
	Sodium bicarbonate, .....	gr. iii.

M. Fiat chartula i.

Sig. To be added to a quart of distilled water.

This solution may be made into sterilized tablets and kept ready for use.—*Journal of the American Medical Association*.

NEW YORK, SATURDAY, JUNE 27, 1908

## THE MEDICAL SERVICE OF THE ARMY.

We would call the attention of our readers to the announcements which we publish in our department of Miscellany this week, under the heading of Army Medical Department Examinations, 1908. Copies of the circulars of information reached us when it was too late for their insertion in full in this issue. In view of the fact that formal applications for permission to undergo the preliminary examination for admission into the Medical Corps should be in the possession of the adjutant general of the army before July 1st, we hasten to publish the condensed statements in question, and shall give our readers further information in our next number.

An appointment as a medical officer of the army or navy has always been coveted by the young graduate, for there is no higher stamp of his merit. If until recently certain conditions of the service have operated to cause many promising and ambitious young physicians to refrain from seeking for this mark of distinction, to the great embarrassment of the service, it is evident that recent legislation has so remedied those deterrent features as to insure a more general determination among eligible men to take the examinations and enter upon a career in the army or navy. And yet, so large is the number of vacancies created by the new law in the Medical Corps of the Army, for several years to come all candidates who pass the examinations acceptably will be practically sure of succeeding in entering the corps, so the heightened attractiveness of the career need cause no competent man to fear

that increased competition will lessen his chances of success.

A notable feature of the recent action of Congress is the creation of the Medical Reserve Corps, such a body as the army has always stood in need of. Heretofore, whenever the emergency of war has made a rapid increase of the number of medical officers absolutely necessary, the personal preferences of civil officials and politicians have led to the appointment of many persons whose unfitness soon became manifest to everybody but themselves. The flower of our profession have now the opportunity of guarding against any further repetition of such an unfortunate state of things, and at the same time of letting their patriotism be known. Some sacrifices on their part will be needed when they are called upon for active service, but they are such sacrifices as every good citizen is ready to make, and, as a class, physicians have never been backward in endeavors to promote the public welfare at any cost to their personal interests. It will soon come to be recognized, we believe, that membership in the Medical Reserve Corps, even in times of peace, will be accounted noble by the people, for whoever stands ready to do a good deed when he is called upon is as meritorious as he who, having the opportunity, actually does it. We are very hopeful, therefore, of the personnel of the new corps, for we look to see it made up of the best men that the profession includes, men who have made their mark in civil life solely by their own fitness and the beauty of their lives—surely a legion of honor.

CHARITY ORGANIZATIONS TO JOIN IN  
RED CROSS WORK.

In the selection of Mr. Ernest P. Bicknell as national director of the American National Red Cross seems to have chosen wisely. His selection as director carries with it the adoption of the policies which Mr. Bicknell has earnestly and ably advocated. The essential idea of the reorganization of the work of the Red Cross Society as outlined by Mr. Bicknell is that all the organized charities in the United States are to be enrolled as auxiliaries to the Red Cross, each organ to be sending to the scene of need at the call of the society. This would give a nucleus of experienced workers whose effort would be much more efficient than those of persons not trained in charity organization work. Under this plan experienced investigators, visitors, nurses, organizers, and administrators, trained to work systematically and effectively, could be assembled at any point in the United States within a few hours, ready to give skilled assistance in the relief

of suffering from any great disaster and to handle and distribute supplies of any kind which might be needed.

The skeleton organization of the society as outlined by Mr. Bicknell provides for the appointment of local representatives in various sections who would at once assume charge of relief measures wherever the services of the society were required, and to this representative the assistants from the various auxiliary organizations will report as soon as they are notified that their services are required. The acts of the local representative will be subject to the approval of the emergency relief board and of the national director, who in cases of grave importance will proceed to the spot himself and assume immediate charge of the work. The plan as set forth by Mr. Bicknell is an excellent one and, as it is based on his experience in San Francisco, we have no doubt that it will prove eminently satisfactory in operation.

#### THE LIMITATIONS OF DISINFECTION.

We often hear grave doubts expressed concerning the value of disinfection of sick rooms after contagious diseases, and are told that results would be equally good if this were entirely omitted. Furthermore, bacteriologists teach us that practically all the tests of the efficacy of disinfection now in use are subject to wide error, and that no standard has yet been discovered by which to make comparative measurements. The difference between tests on naked germs and on germs in the presence of even three per cent. of some form of organic matter may exceed fifty per cent. Hewlett and Kenwood, therefore, prefer to obtain the carbolic acid coefficients of the particular disinfectants to be compared by adding varying dilutions of the disinfectants to a definite quantity of faeces, and, after half an hour's exposure, testing for the survival of *Bacillus coli communis*. At the Lister Institute carbolic acid and *Bacillus typhosus* are the standard chemical and germ employed for ordinary purposes. The organic matter is supplied in the form of a sterilized three per cent. emulsion of human faeces. This is made by drying faeces at 102° C. (215.6° F.), grinding in an agate mortar, suspending the powder in water, and then sterilizing in the autoclave. Blyth advocates the use of milk of a given composition in place of the faeces suspension.

So far as the advisability of disinfecting sick rooms is concerned, a discussion reproduced in a recent number of *Public Health* reflects the prevailing opinions in England. Kenwood is a thorough believer in such disinfection, and urges the frequent disinfection also of school rooms. If possible, these should be cleaned and disinfected at the end of each

week. Colonel Firth, who has had considerable experience with disinfection in the army, boldly advocates omitting disinfection of sick rooms entirely. Even after scarlet fever he makes it a practice not to disinfect the rooms, but disinfects by steam all personal clothing, and trusts to fresh air and soap and water to cleanse the room. Rideal believes this is going too far, and urges the value of disinfection, especially in killing tubercle germs. Defries believes that until we know the precise vehicle of infection in any given case it will be best to disinfect the rooms in order to be on the safe side. It certainly is not well to create a false sense of security by going through an elaborate disinfection and then omitting careful cleansing with soap and water. As a rule, however, the moral effect is just the reverse; the family is impressed with the importance of cleansing, ventilating, and renovating. In this moral effect a great many health officers see the most important rôle of the disinfection of sick rooms.

Several observers spoke of the use of disinfectants to kill vermin. Kenwood had made comparative tests with formaldehyde, chlorine, nitrous acid, and sulphurous acid, and found that fleas were killed only by exposure to the last named. The results with bedbugs were practically the same, so that, for the killing of such vermin, the old sulphur disinfection is to be preferred. In killing lice on the clothing of soldiers, Firth found that a three hours' exposure to formaldehyde produced the best results. The disinfection was carried out in a steam disinfectant with just sufficient steam inside to keep the air moist.

#### MASTURBATION AND ITS CONSEQUENCES.

But very few physicians, we fear, have formed a correct estimate of the influence of masturbation on the physical and mental health of those who practise it. The quacks, of course, depict its alleged direful effects in frightful terms, and, unfortunately, there are some of our textbooks that are not far behind them. The consequence is that many impressionable persons, conscious of having been more or less addicted to the practice in their youth, fall victims to tormenting remorse, accusing themselves of viciousness and of having brought upon themselves an endless succession of physical and mental abnormalities. They feel convinced that they are rapidly drifting into impotence or that they are doomed to end their days in a madhouse.

However clearly we may discern the fallaciousness of the teaching that has given rise to all this unnecessary misery, most of us, in our intercourse with the laity, hesitate to combat it, lest we should be misunderstood as in some way countenancing a

habit which is certainly degrading and is popularly reputed to be vicious and disastrous—so reputed in spite of the fact that it is generally known to be almost universal among young persons. Is it not wise, we are apt to argue, to let the popular impression alone for the sake of some modicum of wholesome effect which it may exert upon masturbators who are in danger of carrying the practice to excess? It must be conceded that the question is a delicate one; however, we believe that more good is likely to come from telling the truth than from refraining.

A remarkable contribution to the true statement of the case was made in our issue for October 9, 1897, in an article entitled *An Investigation Into the Effects of Masturbation*, by Dr. A. C. McClanahan, of Red Lodge, Montana. Dr. McClanahan gave brief accounts of the subsequent careers of a number of men known by him to have been masturbators in their youth, and the narration speaks pointedly in favor of the innocuousness of the habit. It is well worth our readers' while to turn back to the article. Quite recently, in the *Progrès médical* for June 6th, Dr. Maurice Royer has gone over the ground again, and he comes substantially to Dr. McClanahan's conclusions, though he admits that, when carried to excess, masturbation is injurious, but no more so, he implies, than excessive coitus. Incidentally, it is interesting to note that M. Royer, not believing in the syphilitic origin of *tabes dorsalis*, agrees with those who ascribe that affection to excessive indulgence in sexual intercourse. Its frequent occurrence in syphilitic subjects, he thinks, is but a coincidence, depending on the fact that libertines are particularly prone to contract syphilis. He thinks, also, that precocious masturbation, the form sometimes noticed in very young children, may create a *locus minoris resistentie* in the spinal cord and thus pave the way for *tabes*. Such children, as he remarks, are incapable of producing a "terminal spasm" and an ejaculation, but find satisfaction in a partial erection of the penis which they keep up by manipulations continued for hours at a time. It is this protracted sexual excitement, he thinks, which does the harm. Nobody can accuse these infants of viciousness; they generally learn the habit from their nurses' handling, carried out ignorantly or by design, for some unscrupulous nurses do not hesitate to paddy a pugnacious child by titillating its genitals.

As to the part supposed to be played by masturbation in the production of insanity, if all young masturbators are destined to end in an asylum, asks Dr. Royer, will it be possible to find enough *leopard* in them? Masturbation has figured prominently in the etiological table—published in asylum reports and occasionally, an alienist seems to think, that he has probed the etiology of a case to the bottom when he has elicited from an insane patient the admission

(sometimes unfounded) that he or she has been a masturbator. In many an asylum, it is true, we may see a poor inmate almost constantly executing movements which can only be masturbatory, but surely the revolting propensity may quite as well be the result as the cause of mental disease. We have no more right to afflict the friends of an insane person by saying that he or she masturbated himself or herself into insanity than we have to declare that a man drank himself crazy, whereas his insanity, though incipient and latent, may have urged him to drink.

## THE FRENCH MEDICAL MEETING IN QUEBEC.

As we have already noted in our news columns, the Association des médecins de langue française de l'Amérique du Nord will hold its fourth meeting in Quebec on July 20th, to continue until the 22d. The elaborate celebration of the tercentenary of the historic and picturesque old city is sure to attract a great number of physicians from various parts of Canada and the United States, including many whose native tongue is not French, and they will naturally be interested in the meeting. So great a concourse of visitors is expected, indeed, that the hotels are not making reservations of rooms on order. While this fact is proving decidedly embarrassing to the committee on quarters, they are able to announce that 400 rooms, with or without partial or complete board, have been placed at their disposal, at charges ranging from \$2 to \$5 a day. The secretary of the committee is Dr. Emile Nadeau. It appears to be decided, the committee say, that there will be a city of tents, with all the necessary conveniences, including running water, drainage, electric lights, service, police, and restaurants, which will also be open to physicians attending the meeting. The Canadian transportation companies have arranged for half rates, and a similar action has been taken by the railway companies of the eastern part of New England. It is altogether probable, therefore, that medical men who visit Quebec for the occasion will be able to make the trip comfortably and economically, and it seems to us that the association may count on a very large and satisfactory meeting.

## A CONSOLIDATION OF SCOTTISH JOURNALS

It is announced in the June number of the *Scottish Medical and Surgical Journal* that there will be no further issue of that journal, for it is to be consolidated with the *Edinburgh Medical Journal*. For the eleven years of its existence the journal has published two issues monthly and one

esteem for its excellence, and it cannot be doubted that the consolidation will give Edinburgh a journal of heightened usefulness and influence. It was consequent upon the acquirement of the *Edinburgh Medical Journal* by members of the profession. The new journal will be edited jointly by the senior editors of the constituent journals.

## JUSTICE TO THE CONVICT.

In *Charities and the Commons* for May 9th there appears a letter written by Dr. Beverley Robinson, who has long shown a most philanthropic interest in the inmates of our penal institutions. Dr. Robinson mentions two ways in which complaints by prisoners might be listened to without hindrance and with some chance of avail. The first one is by frequent visits by authorized persons at unexpected hours, and the other is by allowing prisoners to write to the State Prison Commission as often as once a month without the knowledge of the prison officials, or, at all events, without the letters being opened before they are mailed. When we remember that insanitary conditions often form the burden of complaints, it will be realized that the medical profession ought to cooperate with Dr. Robinson.

## News Items.

**Stray Dogs Condemned.**—In view of the occurrence of several cases of rabies recently, the Board of Health of the City of New York has adopted an ordinance providing for the destruction of all stray dogs.

**The Medical Department of the Temple University, Philadelphia,** held its commencement exercises on the evening of Wednesday, June 3d. The degree of doctor of medicine was awarded to eight candidates.

**The Antituberculosis League of New Orleans** has organized a branch league at Winnfield, La., with the following officers: President, Dr. J. J. Peters; vice president, Dr. I. E. Siess; secretary, Miss Georgia Prothro, and treasurer, Mr. S. G. Fittz.

**Jewish Hospital, Philadelphia, Home for Nurses.**—The corner stone for a home for nurses and a surgical ward, to be known as the Pennsylvania Building, was laid with appropriate ceremonies on the grounds of the Jewish Hospital, Philadelphia, on Tuesday, June 2d.

**Donation to the Syracuse, N. Y., Hospital for Women and Children.**—Mrs. Mead Belden has given \$5,000 to this institution, to endow a bed in the Holden pavilion for children. This gift in perpetuity is to be a memorial to Mrs. Belden's son, Edward Mead Belden.

**An Annex to Roosevelt Hospital.**—Plans have been filed for a two story pavilion which is to be erected as an addition to Roosevelt Hospital. The pavilion will be fitted as a pathological annex, with apparatus for microscopical work. It has been presented to the hospital by Mr. James W. McEune.

**Contagious Diseases in Chicago.**—The following cases of communicable diseases were reported to the Department of Health during the week ending June 13, 1908: Measles, 227; diphtheria, 94; scarlet fever, 67; whooping cough, 41; tuberculosis, 40; chickenpox, 17; typhoid fever, 9; diseases of minor importance, 4; total, 497.

**The Hartford Celtic Medical Research Society** is the name of an organization recently formed in Hartford, Conn., with the following officers for the first year: President, Dr. D. F. Sullivan; vice presidents, Dr. Edward J. Thurbert, and Dr. Thomas F. Welch; treasurer, Dr. P. R. McPartland; secretary, Dr. J. F. Rooney.

**The Northwestern Medical Association of Philadelphia** held a stated meeting on Friday evening, June 26th, which was the last meeting of the association until the second Friday in September. The principal feature of the programme was a paper by Dr. Moses Behrend on the Diagnosis and Treatment of the Enlarged Prostate Gland.

**Philadelphia County Medical Society.**—A meeting of the Central Branch of this society was held on the evening of June 24th. Dr. James W. Walk presented a communication on Avoidable Mistakes in Medical Testimony, and Dr. Henry Leffmann delivered an address on Naturalization and Socialization of Medical Education The Only Method of Suppressing Quackery and Illicit Practice.

**Tufts Medical College** held its fifty-second annual commencement exercises on June 17th. Two hundred and forty-seven degrees were conferred, which breaks all previous records. At the annual dinner of the alumni association Dr. Morton Prince delivered an address in which he made a plea for donations for laboratories and endowment to enable Tufts to take the lead in establishing a course in psychotherapeutics.

**Night Camps for the Tuberculous.**—Dr. Livingston Farrand, secretary of the National Association for the Prevention of Tuberculosis, says (*Charities and the Commons*, June 20, 1908) that night camps are needed for tuberculous patients who are still well enough to continue their work. These night camps should provide the patient with dinner, a place to sleep out of doors, and a good breakfast before going to work.

**Appointments at Cornell University, Ithaca, N. Y.**—Dr. Sutherland Simpson, of the University of Edinburgh, has been appointed professor of physiology, and Dr. Andrew Hunter, of Leeds University, has been appointed first professor of biochemistry. Dr. Dennie Hammond Udall, professor of veterinary medicine in Ohio State University, has been appointed acting professor of veterinary medicine, to succeed Dr. James Law.

**Tuberculosis Camps.**—The idea of tuberculosis day camps for patients suffering from tuberculosis, which originated in Germany, was first introduced into this country in Boston by the Boston Association for the Relief and Control of Tuberculosis, which established a camp on Parker Hill, maintaining it from May until November. The movement has spread rapidly throughout Massachusetts, and excellent results have been reported.

**The Associated Physicians of Long Island** held their summer meeting at the Penataquet Corinthian Yacht Club, Babylon, on Saturday, June 10th. About seventy-five members were present. Among those who presented papers were Dr. Louis Nott Lanehart, of Hempstead; Dr. Russell S. Fowler, of Brooklyn; Dr. Arthur H. Bogart, of Brooklyn; Dr. Archibald Murray, of Brooklyn; Dr. Walter Truslow, of Brooklyn, and Dr. Frederick Tilney, of Brooklyn.

**The Upper Cumberland Medical Society, Tennessee,** held its annual meeting recently in Sparta, Tenn. Officers for the ensuing year were elected as follows: President, Dr. B. S. Rhea, of Bon Air; first vice president, Dr. J. T. Moon, of Algood; second vice president, Dr. T. J. Potter, of Smithville; third vice president, Dr. W. M. Breeding, of Livingston; secretary, Dr. V. L. Lewis, of Crossville; treasurer, Dr. R. E. Lee Smith. The next annual meeting will be held in Cooksville.

**An Antituberculosis Society in Newfoundland.**—A society for the prevention of the spread of tuberculosis has been organized in the colony of Newfoundland, whose special province will be to instruct the general public as to the best methods of preventing the spread of this disease, which is the cause of a very large proportion of the deaths of the colony. The various missionary societies are taking an active part in the work, having provided trained nurses for settlements where the inhabitants agree to pay the expenses of the nurses.

**Dr. Meyer Director of the Henry Phipps Psychiatric Clinic.**—The trustees of Johns Hopkins Hospital and University have elected Dr. Adolph Meyer, of New York, professor of psychiatry and director of the Henry Phipps psychiatric clinic, which is to be erected and maintained out of the fund donated for that purpose by Mr. Henry Phipps, of Pittsburgh. Dr. Meyer will spend the summer abroad with the architect who is to erect the buildings making a study of similar institutions at Munich, Berlin, and Breslau, and will take up his residence in Baltimore in the fall of 1909. Dr. Meyer has served as director of the clinic at the Hospital for the Insane in Worcester, Mass., director of the pathological institute of the New York State Hospital on Ward's Island, since 1904 has been professor of psychiatry at the Medical Department of Cornell University, and is now president of the New York Psychiatric Society.

**Oregon State Medical Association.**—The thirty-fourth annual meeting of this association will be held in Portland on Wednesday, Thursday, and Friday, July 1st, 2d, and 3d. A splendid programme consisting of over twenty papers has been prepared, and ample arrangements have been made for the entertainment of the visiting members and their guests. The general sessions will be held in the Assembly Hall of the Commercial Club, and the meeting of the House of Delegates will also be held at this place. A public meeting under the auspices of the Oregon State Board of Health will be held on Friday afternoon. The officers of the association are as follows: President, Dr. R. C. Coffey, of Portland; first vice president, Dr. Nicholas Molitor, of La Grande; second vice president, Dr. J. H. Rosenberg, of Prineville; third vice president, Dr. A. C. Seeley, of Roseburg; treasurer, Dr. Edna Timms, of Portland; secretary, Dr. William House, of Portland.

**New Head for the Red Cross Society.**—Ernest P. Bicknell, who has been appointed national director of the American National Red Cross Society, served for five years as secretary of the Indiana State Board of Charities, during which time he brought about several important reforms, both in the charity work and in the penal system of the State, introducing the indeterminate sentence and the parole. Mr. Bicknell also had charge of the Chicago Bureau of Charities for some years, taking active part in the investigations of the County Hospital and serving as a member of the present commission charged with the building of a new Cook County Infirmary and Tuberculosis Hospital. Mr. Bicknell showed distinguished ability in work of relief at San Francisco, where he went to represent the Chicago Relief Committee, which contributed \$700,000 to the relief fund, and it was while there that he evolved the idea of making charity organizations generally auxiliary members of the American National Red Cross Society, with the view to giving a nucleus of trained relief workers who could be called upon for immediate service in case of emergencies. It is announced that this plan will at once be put into effect.

**The Health of the Canal Zone.**—During the month of April, 1908, the following deaths from transmissible diseases occurred in the Canal Zone: Typhoid fever, 1; zoster-autumnal malaria, 2; clinical malaria, 20; dysentery, 5; amoebic dysentery, 1; beriberi, 2; purulent infection and septicæmia, 4; tuberculosis of the lungs, 26; general tuberculosis, 3; cancer and other malignant tumors, 4; acute articular rheumatism, 1; elephantiasis, 1; tetanus, 3; bronchopneumonia, 3; pneumonia, 16; diarrhoea and enteritis, under two years of age, 15. The total deaths for the month numbered 104 in a population of 116,178, corresponding to an annual death rate of 20.04 in 1,000 of population. The health of the employees of the canal commission was exceptionally good. There were no deaths from typhoid fever among them, and only one death from malaria. In 1907 there were 816 cases of malaria treated in the various hospitals, with 10 deaths; in 1908 there were 407 cases of malaria treated, with no deaths. The decrease in the number of cases of malaria was accompanied by a decrease in the severity of the type of the disease. The sick rate among the employees made quite as good a showing as the death rate. In 1907 the rate was 21.52 in 1,000; in 1908 it was 17.09 in 1,000. Plague is present at Guayaquil and at La Guayra, but no case has been discovered on the isthmus. No case of yellow fever

## Pith of Current Literature.

### THE BOSTON MEDICAL AND SURGICAL JOURNAL

June 18, 1908.

1. An Account of Dr. Louis Daniel Beauperthuy, a Pioneer in Yellow Fever Research.  
By ARISTIDES AGRAMONTE.
2. Suture of the Patellar Tendon: Report of Three Cases.  
By CHARLES F. PAINTER.
3. Notes on X Light. Note 208. The Resistance of an X Light Tube Is not an Accurate Indication of the Degree of the Vacuum,  
By WILLIAM ROLLINS.
4. Modern Medicine and Surgery in the Orient,  
By J. EWING MEARS.

2. **Suture of the Patellar Tendon.**—Painter describes his method as follows: The incision is a straight one directly over the patellar tendon, beginning at the tibial tubercle and extending up over the lower half of the patella. The sheath of the patellar tendon is fully three quarters of an inch in breadth, and at its attachment to the patella is separated from the synovial membrane by quite a thick layer of subserous fat. In elderly patients this fat may be so atrophied that the synovial membrane is practically a part of the posterior surface of the patellar tendon. If the rupture has been of long standing there is likely to be considerable contraction of the divided tendon, and in these cases it is necessary to employ the method of Lange, devised for the purpose of transmitting the power of a muscle at a distance where there is no intervening tendon of sufficient length. In one case the writer used braided pedicle silk, bridging over the entire distance between the tibial tubercle and the patella. Four strands of this silk were placed parallel to each other, being attached above to the marginal cartilage of the patella by threading through holes drilled in the cartilage, and below they were quilted through the patellar tendon. A fascia was then closed over these sutures with interrupted catgut, and the skin united with a buried silkworm gut. In two cases where there had been but little retraction it was possible to approximate the cut ends of the tendon quite closely to the lower border of the patella. It was always necessary to drill holes in the margin of the patella. The leg was then put up in plaster of Paris in complete extension and was not again disturbed, except for the removal of the skin suture, until six weeks had elapsed. The plaster was then split and taken off each day to permit of passive motion. During the next two weeks the patients were allowed to bear weight on the leg, protected by the plaster. At the end of a month, or ten weeks after the operation, motion was possible to nearly a right angle, and walking was then permitted without the protection of any splint. Crutches were used for the first six weeks and then a cane for the next month. Protection by a flannel bandage was urged for two or three months after the omission of the plaster. The functional results have been entirely satisfactory. There has been a loss of not over 5 degrees of extension in any case, and this has not seemed to materially interfere with function. In one of his cases where Lange's method was employed one strand of the silk used to bridge over the hiatus worked its way to the surface, after being in place six months. This required a careful dissection in order to avoid the removal of the entire network. It also gave opportunity to obs-

serve the way in which a new tendon was being formed, fibrous tissue having enveloped these strands throughout their entire extent.

#### THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

June 20, 1908.

1. The Treatment by Rest, Seclusion, Etc., in Relation to Psychotherapy, By S. WEIR MITCHELL.
2. Cooperative Scientific Investigation. Address of the Chairman of the Section on Ophthalmology, By WILLIAM H. WILDER.
3. Autointoxication, By G. E. DE SCHWEINITZ and CHARLES A. FIFE.
4. Tonsillotomy in Children Under General Anesthesia—a Hospital Operation, By EDWARD PANCHON.
5. Marriage and Intermarriage of Tuberculous Subjects, By I. A. MCSWAIN.
6. Thymic Asthma, with Report of a Case of Thymectomy and Resection of Enlarged Thyroid in Child Twenty-three Days Old, By J. SCHWINN.
7. The Conjunctival Tuberculin Reaction, By CHARLES PATTON CLARK.

**5. Marriage and Intermarriage of Tuberculous Subjects.**—McSwain thinks the public should be informed by distributing circulars written in language that can be understood of the danger of intermarriage and marriage of tuberculous subjects. Public exhibitions have a large influence on the public mind; school and home training is important, and public lectures create interest as perhaps nothing else can. Physicians in their close contact with the home should certainly impress the young people of the danger of the marriage of consumptives and strongly oppose it. Then, some time in the future, when the beneficial effects of education are manifest and sanitary laws properly executed have curtailed the ravages of the disease, for the incorrigible ones who will not be governed by reason, the dignity and majesty of the law should be invoked. Thus can we teach them that it were better for a few to practise selfdenial than that many should suffer for their indulgence. Tuberculous subjects should be taught in the most impressive way that to marry and intermarry will inevitably bring much sorrow to the household, that they will but hasten themselves into untimely graves to leave behind them, perchance, a sickly posterity that will be liable to succumb to the disease. Let us instill high ideals in the minds of the young people. That their purposes in life should be to bless and elevate mankind, that the temporary joys of the marriage of diseased persons are soon to be overshadowed by thick clouds of sorrow and disappointment. Better endure the loneliness, and even the stigma, of single life than to behold the destructive sequel that follows in the wake of marriage in such cases.

**6. Thymic Asthma.**—Schwinn states that in well developed cases of thymic asthma we find the symptoms of a stenosis of the air tract somewhere between the larynx and the bifurcation of the trachea; inspiratory and expiratory stridor, as a more or less audible whistling respiration; retraction of the supraclavicular, infraclavicular, and intercostal spaces during inspiration; inspiratory dilation of the nostrils, and more or less cyanosis and restlessness. Most any time these symptoms may assume a most dangerous character, the respiration becoming extremely labored, the patient becoming blue or almost black. Consciousness is lost, convulsion may

set in, and, with a rapid, weak pulse, death may follow in the course of a few minutes. Potts reports four cases where children died with the symptoms of suffocation within two minutes after the insertion of a tongue depressor. A child may show very slight symptoms of difficult respiration, and suddenly in the midst of a crying spell or during an exciting play become cyanosed and perish with symptoms of suffocation. Inspection and palpation are as a rule negative in thymic enlargement, except where the gland is quite large and forms a visible and palpable swelling in the suprasternal notch. Percussion often brings out an abnormal dullness over the upper part of the sternum, while auscultation may show diminished breathing and abnormal tracheal sounds. The voice is generally unchanged, except that it may be weak. The fact that in a case of obstruction to respiration the usual intubation gives no relief, while the intubation with the use of a long tube removes the stenotic symptoms, would point to the thymus as the cause of the obstruction. Chevalier Jackson was enabled, by the use of a bronchoscopic tube introduced by tracheotomy, to see directly the narrow slit to which the trachea was reduced by the pressure of the enlarged gland; but of all the diagnostic means the radiogram is the most trustworthy. The enlarged gland throws a shadow different from that of the normal gland in that it reaches farther to the side of the vertebræ and merges into the shadow of the heart in a convex line instead of in a rather straight line. The condition being such that a child with a large thymus may suffocate at any moment, it is very plain that surgery, and prompt surgery at that, is the only rational procedure. The medical treatment may bring down a syphilitic enlargement in time, but it surely will not reduce a simple hypertrophy far enough to keep the patient safe until this reduction is accomplished. Some authors advise us to keep a child of this kind quiet, see that it does not throw the head back, keep it from crying and excitement, keep away infectious diseases, etc. All of this is very nice, but who can watch an otherwise healthy child day and night for years in its every movement? Operation with the view of removing the offending organ seems to the author the only treatment to be thought of, and in the few cases where this was carried out the results certainly have been all that could be expected. But there is still that class of cases left in which there are no symptoms whatever, until suddenly and without warning a child is seized with a suffocating attack and expires before help can be had. In a considerably greater number of cases of sudden death in children than we imagine at present the thymus is in all probability in blame. In cases of this kind we are utterly in the dark until after the catastrophe, and the only way to prevent such deaths would be a systematic radiographic examination of children. The operation should be performed as soon as a diagnosis is made, the radiographic method being the most reliable of our diagnostic means. A tracheotomy should be provided for in every case, but avoided if possible on account of the danger of infecting the mediastinum. The upper chest aperture should be temporarily enlarged by the splitting of the sternum, if during the operation the thymus is increasing at all. In the future it will be possible to

avoid tracheotomy in a number of cases. General anaesthesia should be used, as it is very difficult to operate upon a struggling child.

#### MEDICAL RECORD.

June 20, 1908.

1. Milk Free Fluid Diet, and Rectal Irrigations in Typhoid Fever—A Further Report, By A. SEIBERT.
2. A Milk Free Diet in Typhoid Fever, By CYRUS J. STRONG.
3. Remarks on Milk Free Fluid Diet and Rectal Irrigations in Typhoid Fever, By ROBERT C. KEMP.
4. Clinical Charts of a Case of Quartan Malarial Fever Observed in West Africa, with Commentary, By F. CREIGHTON WELLMAN.
5. The Relation of Tuberculous Cows to Tuberculosis in Children, By WILLIAM LELAND STOWELL.
6. The Treatment of Diseases Due to Respiratory Catarrh, By WILLIAM MARTIN RICHARDS.
7. The Injurious Habits and Practices of Childhood; Their Detection and Correction, By KARL H. GOLDSTONE.

**1, 2, 3. Milk Free Fluid Diet, and Rectal Irrigations in Typhoid Fever.**—Seibert has used plain warm water in irrigating the colon in typhoid fever. He observes the following rules: If nausea is present on admission, the stomach is washed out. Then two doses of calomel, each containing two grains, are given within two hours. Rectal irrigations with three pints of warm water are begun at once. In severe cases every three, in milder ones every six, and in mild cases every twelve hours. Bowel hemorrhage, appendicitis, and perforations are the only contraindications. During the first day of treatment nothing but cold water is given. From the second day on, one half pint of strained rice, oatmeal, or barley soup, containing the extract of half a pound of meat and the yoke of a fresh egg, well spiced, are given every three hours, five times daily. During the night cold water alone is offered. During the first three days of treatment the patients are not urged to swallow all of their soup, but are persuaded to drink cold water every hour by day and by night. From the fourth day on, strained pea, lentil, potato, and tomato soup, with rice, are added to the menu. The desire for more food, coming in uncomplicated cases not seldom on the fifth or sixth day, is met by giving the soups thickly made. The lower the fever and the more marked the hunger, the thicker the soup. To very hungry patients two or three zwiebacks are given with their soup at the end of the first week. Orange juice is given in water three times daily. Egg albumen is not given, on account of the possibility of forming toxins. Before each meal fifteen to twenty-five drops of hydrochloric acid are given in one half ounce of water. Alcohol is given only to topers. Cold baths are never employed, even in hyperpyrexia. Opium is used only in bowel hemorrhage. During complicating pneumonia sixty to one hundred and twenty drops of 20 per cent. camphorated oil are injected hypodermatically, twice daily. No other medication is used. The results of this plan of treatment have been the following: Nausea, headache, delirium, insomnia, tympanites, and diarrhea disappeared in most cases after two or three days, and did not recur later on. In uncomplicated cases the temperature began to drop after twenty-four to forty-eight hours daily by  $\frac{1}{2}$  to  $1^{\circ}$  F., and reached  $99^{\circ}$  F. in the rectum on the morning of the ninth, tenth, eleventh, or twelfth day of treatment,

irrespective of the duration of the attack before admission. In a smaller number of cases this occurred within the first week of treatment. In cases admitted with complications (like pneumonia, nephritis, and phlebitis) the intestinal symptoms (tympanites and diarrhoea), as well as those of systemic infection of the nervous system (delirium, headache, and insomnia), usually disappeared as readily as in uncomplicated cases, while the temperature, the pulse rate, and the respirations remained at the height characteristic of the local processes. The complications disappeared more readily than under the former milk diet. Later complications very seldom developed in cases admitted without complications. The author thinks that it abbreviates the attack and ameliorates the symptoms by the constant reduction of infectious material; it prevents complications, and it reduces the mortality.—Strong has treated seventeen cases with the milk free diet, and speaks very favorably of it.—Kemp is also in favor of Seibert's method. His only modification of this method is in cases of complicating nephritis of active type, where beef broths are omitted; but the strained farinaceous gruels are kept up, and occasionally he uses malted milk made up with hot water. Moreover, he has been employing of late in his gastrointestinal cases a sterilized milk albumin product containing glycerophosphoric acid, which is soluble in water and has been demonstrated by Ewald to have considerable nutritive value and to be readily absorbed in typhoid fever. In such cases the author believes it would be of considerable value. Strong remarks that the use of rectal irrigations is one of the most important features in the treatment of typhoid fever. He has generally employed the short recurrent tube and normal saline solution. The only contraindications are hemorrhage and peritonitis. By the irrigations the small intestine is emptied out into the large intestine, and this in turn cleared out; absorption from accumulation in the rectum is prevented, and hence toxæmia is lessened and the temperature is reduced; gas, if present, is removed from the bowel; the large intestine is kept clean, and elimination of the toxins, through the diuretic action of the injections on the kidneys, is promoted.

**5. The Relation of Tuberculous Cows to Tuberculosis in Children.**—Stowell says that fresh, clean milk, when obtainable, is wholesome and more readily digested than when pasteurized. The danger of tuberculous infection from milk must be very slight, for, in tracing the history of the children and the diagnosis on admission to the institution, there is no evidence of tuberculosis developing more often among those having the farm milk than among those in other wards having the pasteurized supply from the city. Less than 10 per cent. of the mortality was due to tuberculosis, and that, according to the United States Census of 1900, is the ratio for the nation. We cannot deny the presence of a tuberculous dairy and the presence of tuberculous children; but a careful analysis fails to show that one depended on the other.

**7. The Injurious Habits and Practices of Childhood.**—Among other injurious habits, Goldstone mentions the pacifier. He believes it to be one of the most pernicious and harmful habits of infancy. It is found among all classes of people.

The good influence that it is supposed to exert—imaginary, as can be seen—is to quiet the child, stop its crying, take the place of feeding, and allay the symptoms of teething (?). The pacifier can be said to quiet the child only in the same sense as body sucking and masturbation quiet or rather satisfy the child, but only to be replaced by the reaction of a mental explosion, the result of high nervous tension. It takes the place of feeding only if one were to consider swallowing of dirt and germs as feeding. The sucking of the pacifier produces in infants (1) the formation of adenoids by causing a congestion of the postpharyngeal wall, and consequent hypertrophy of the lymphoid tissue situated between the two Eustachian tubes and known as the pharyngeal tonsil; if adenoids are already present, they increase in size and extent for the very same reasons. (2) Deformities of the mouth and palate by the presence of adenoids, whose growth it incites, and by the repeated twisting and distorting caused in sucking. Children who are subject to the habit have a high arched palate, diseased and deformed teeth, and thickened lips. (3) Colic and flatulence, by the sucking in of air. (4) Ulcerative stomatitis and sprue, by the sucking of dirty particles that always collect on the pacifier. (5) Hypertrophied tonsils, due to congestion as mentioned in adenoids.

9. Plastic Resection of the Breast and its Bearing on the Preliminary Incision of Breast Tumors, By C. H. WHITEFORD.

1. **Cerebral Influenza.**—Saundby discusses the chief clinical features of cerebral influenza and the nature of the morbid processes to which it is related. After citing a number of illustrative cases, he takes up the pathology of the disease, and summarizes the post mortem findings as follows:—In some cases there is only congestion, in others meningitis of the vertex or base, in others again acute hemorrhagic encephalitis, associated in certain instances with hæmorrhage or red softening. Bacteriological examination either reveals no organism, or streptococci, Pfeiffer's bacilli, or pneumococci. It is not improbable that the meningococcus may cause some of the cases, for there is evidence to show that the effect of the influenza poison is to cause into activity any latent organisms and to diminish constitutional resistance to their attacks. So that there may be recognized a series of cases of purely influenzal origin, and, secondly, one in which influenza forms merely the soil where other disease germs find the conditions favorable to their development. True cerebral influenza may cause first, a state of cere-

bral intoxication which passes off without doing serious damage. Next there are cases in which the poison causes intense and fatal congestion with minute meningeal hæmorrhages. Beyond these the disease passes on to inflammation of the meninges, and lastly we have acute hæmorrhagic encephalitis with hæmorrhage or red softening. The symptoms of cerebral influenza are these: Usually after a short period, ranging from one to four days, during which the patient shows signs only of catarrh (and this may be wanting in some cases), he is seized with intense headache, with or without vomiting, or neuralgia or an epileptic or apoplectic fit or aphasia, or there may be facial paralysis, monoplegia, or hemiplegia, for the cerebral symptoms may be ushered in by any one of these symptoms. There may be a preliminary period of restlessness, with or without delirium; in others stupor or unconsciousness develops gradually or suddenly. There is usually fever, varying in amount. The muscles are often rigid; stiffness of the neck, opisthotonos, as especially contraction of the masseters and trismus, have been frequently noted. There may be twitchings of the limbs, or clonic spasms of the head or extremities, disturbances of vision, inequality or irregularity of the pupils, paralysis of the sphincters, and *tâche cérébrale*. The reflexes are generally preserved, and Kerig's sign is never mentioned as having been present. Optic neuritis is occasionally seen. Albuminuria is of infrequent occurrence. Cheyne-Stokes breathing sometimes is present. The prognosis should always be guarded, but not hopeless. The gravest condition appears to be complete coma, general relaxation of the limbs, rising temperature, and Cheyne-Stokes breathing. The presence of ear trouble, of organic disease of other organs, of arteriosclerosis, or advanced age are bad features, while youth, previous good health, and a sound constitution afford a basis for hope. The duration of the fatal cases varies from two to fourteen days; usually it is about a week. As regards treatment, we are to a large extent powerless. If the patient can take medicine by the mouth, small doses of quinine should be given. The diet should consist of milk, beaten up eggs, and weak coffee with milk; if there is inability to swallow, rectal feeding should be tried, and, if the sphincters are relaxed, subcutaneous injections of salt solution should be given.

2. **Hemiplegia and Unilateral Optic Atrophy.**

Williamson reports a series of cases of a peculiar combination of symptoms—optic atrophy on one side, with hemiplegia (or hemiparesis) on the opposite side. Such symptoms could be produced by an obstruction (thrombosis) of the internal carotid and middle cerebral, with occlusion of the central artery of the retina by thrombosis or embolism.

9. **Preliminary Incision of Breast Tumors.**

Whiteford's conclusions are as follows: 1. Every breast tumor should be incised prior to its removal. The surgeon who, in performing a radical operation for supposed malignant disease of the breast, neglects the elementary procedure of incising the tumor as a means of either confirming or disproving the diagnosis, runs the risk of finding himself in the unfavorable position of having performed a needless or some equally expensive operation for a simple tumor such as an adenoma or fibroadenoma. 2. The explor-

tory incision should not be made through the skin which overlies the tumor. An incision made into the tumor through the overlying skin, in the event of the tumor proving nonmalignant and needing only local removal, results to a certainty in a scar and probably in a depression. This scar, or scar plus depression, if situated in the upper half of the breast, interferes with the wearing of a low necked dress. 3. For exploration of, and, if innocent, for removal of, tumors situated in the upper hemisphere of the breast the incision and method of Collins-Warren should be employed, because, in the event of the tumor proving innocent and needing simply local removal, this method prevents a disfigurement which, to a sensitive patient, is distressing, and, surgically, is unnecessary.

1. **Myoma of the Uterus.**—Martin, in the first of the Ingleby lectures, discusses certain of the dangers connected with myoma of the uterus. Hæmorrhage from the uterus is the commonest symptom of myoma and is present in the great majority of instances. It varies much in different cases. The nearer the tumor to the cavity of the uterus, the more severe the flooding. Thus in the subserous growths it is slight, in the interstitial it is profuse, and in the submucous and polypi it is excessive. In some cases there is constant dribbling of watery blood stained fluid. It is rare for a patient to actually bleed to death from myoma. There usually develops a condition of marked chronic anæmia, which is the chief cause of the brown atrophy and fatty degeneration of the heart muscle, which occurs in many cases of neglected fibroid. It is also the main factor in producing thrombosis and phlebitis of the veins of the pelvis and lower limbs, and secondary embolism of the pulmonary artery. Uncomplicated myomata do not, as a rule, give rise to much pain—never anything approaching the agonies of cancer. Most patients complain only of discomfort and uneasiness. But other complicating lesions, such as adherent and inflamed ovaries and tubes, may cause severe pain. The pressure symptoms are numerous and may call for surgical treatment. Among them may be mentioned constipation, hæmorrhoids, varicose veins of the legs and vulva, neuralgia, sciatica, and even retroflexion or complete

prolapse of the uterus. But the more serious and distressing group of symptoms are those due to pressure on the urinary organs. Retention of urine, either sudden or of gradual onset, is quite common. It is generally due to a fibroid on the posterior wall of the uterus, retroverting the uterus, and pushing the cervix forwards against the pubes. Cystitis seldom occurs as a result of myoma, except by infection through a dirty catheter. Pressure on the uterus is most apt to develop where the tumor is developing in the broad ligament. Disease of the uterine appendages frequently complicates myoma. Myomata are peculiarly liable to various kinds of degeneration, secondary changes being found in about twenty per cent. of the cases. They may be divided into three groups: (1) Nonmalignant degenerations without necrosis, occurring in about fourteen per cent. of myomata; (2) nonmalignant degenerations with necrosis, occurring in about four per cent.; and (3) malignant degenerations and complications, also occurring in about four per cent. There are three modes by which a "natural" cure of a myoma may take place: 1. A submucous fibroid may necrose or slough away, or it may be extended through the cervix as a polypus and drop off. The risks are of course much greater than the most formidable of the modern operations for fibroids. 2. A myoma may participate in the involution of the puerperium and disappear. This is very uncertain and is more apparent than real. 3. A natural cure may occur by the absorption and disappearance of a fibroid at the menopause. At one time this was looked on as a certainty, but as a matter of fact the presence of a fibroid delays the natural change of life, and instead of the hæmorrhages ceasing at forty-five they may go on until the patient is well over fifty. Further, it is just at this period of life that the most serious forms of degeneration are apt to occur. Considering the safety and the certainty of cure offered by modern surgical operation, we are not now justified in advising a patient with a troublesome fibroid to wait for the menopause.

2. **The Suprarenal Capsules.**—Schäfer, in the second of the Oliver-Sharpey lectures, sums up the results of his observations as follows: There is little doubt but that the suprarenal capsules are related in some way to metabolic changes in the tissues and organs. This is indicated by the symptoms of Addison's disease. Some of these symptoms can be referred to absence of medullary secretion. But others, such as the wasting and the malnutrition expressed by the abnormal pigmentation of the skin and mucous membrane, cannot be referred to the medulla, and are probably the result of disease of the cortex. In assuming that the cortex of the organ subserves through its internal secretion certain functions connected with metabolism, there is an analogy to the pituitary body. In this we have an instance of a small ductless gland, partly epithelionervous and partly purely epithelial in structure and origin, the two parts having different functions, though bound up together into a single organ. Of the two parts, the nervous part, as in the suprarenals, produces a substance or substances known as "hormones," which influence the circulatory organs and certain externally secreting glands—in the case of the suprarenals it is the salivary glands, in that of

the pituitary it is the kidneys which are specially stimulated. The purely epithelial part of the pituitary, however, is closely connected with the growth and nutrition of certain of the connective tissues, and especially of the bones, hyperplasia of the organ being accompanied by symptoms of gigantism and acromegaly. So that there is some justification for inferring that the cortex of the suprarenals may yield a hormone which influences the growth and nutrition of certain tissues and organs—it may be that the integumentary tissues and the generative organs—with the relative development of which it is manifestly correlated—are directly under its influence.

6. Ethyl Chloride as a General Anesthetic in Minor Surgery.  
By E. M. BLACKWELL.

1. **Antityphoid Inoculation in the British Army.**—Leishman observes that question of the inoculation of large bodies of soldiers, at a few days notice, on the outbreak of war appears to be one for the grave consideration of all who are responsible for the health of the troops. The objections and difficulties of such a proceeding are obvious and should be anticipated and, if possible, avoided. In modern warfare little time is given for preparation, and the moment of mobilization is not the moment for the carrying out of an operation which may result in the incapacitating of the soldier for twenty-four or forty-eight hours, to say nothing of the possible dangers of a negative phase. Compulsory inoculation, in time of peace, renewed perhaps from time to time, appears to be the ideal to be aimed at; but before this could be carried out, it would be necessary to have the protective value of the inoculations proved beyond doubt and universally conceded. However hopeful some of us may be as to the future, it cannot be said that that moment has yet arrived.

4. **Classification of the Effects of the Sun's Rays and of Artificial Heat.**—Corbusier classifies attacks from the sun's rays and from artificial heat thus: 1. *Syndrome insolationis*—that pathological condition in which the actinic rays are the predominant factor, characterized by violent headache, vomiting; dryness of mucous membranes; very high temperature; rapid pulse; intense thirst; regular and intermittent; cyanosis; intensely hot skin; first moist then dry, deep or stertorous breathing; absence of normal and other reflexes; sallow sallow tendinum and convulsions; unconsciousness; contracted or irregular pupils; scanty urine; coma or sudden death. Dr. Warthin, Professor of Pathology at the University of Michigan, studies the pathological findings in cases affected by the ultra-violet rays to be chiefly exudative, accompanied with marked hyperemia and scattered hemorrhages through the cortex. These findings account for

many of the symptoms just mentioned and particularly distinguish this disease from the effects of heat alone. These symptoms may occur while the patient is in the sun or may not manifest themselves until many hours after exposure. 2. *Sunstroke* (suntraumatism)—cases due chiefly to sun heat but in which the actinic effect may play some part; characterized by sudden fainting and quick recovery; or else mental and physical fatigue; thirst; headache; vertigo; confusion; photophobia; pain in the limbs; injected cornea; skin moist and cool; perhaps nausea and vomiting; rapid, shallow respiration, never stertorous; small, compressible pulse; normal or subnormal temperature; pupils normal or dilated; no complete loss of consciousness; reflexes present; perhaps irritable bladder; more rapid recovery than in *siriasis*. These cases occur when the subject has been exposed to the sun, particularly while undergoing physical exertion. This condition is often a precursor to a more severe attack developing into true *siriasis*. 3. *Heat exhaustion* (heat stroke)—effects of artificial heat alone; characterized by symptoms quite similar to those just mentioned; headache; vertigo; moist, cool skin; shallow respirations; small pulse; subnormal temperature, being characteristic.

10. Remarks on an Artificial Synovial Fluid.  
By ROBERT J. MOORE.

3. **Cases of Isochymia Simulating Gallstone Disease.**—Einhorn reports three such cases; from these it can be seen how the benign isochymia simulates gallstone disease. The author gives the distinctive diagnosis in the following way: in benign isochymia the attack does not come abruptly, it usually lasts a week or more. Pain in upper abdomen is diffuse, intense, but not colicky; manageable without the use of morphine. There is vomiting of large quantities of food, containing usually food from the previous day. The brim of the gallbladder is enlarged, tense, and tender. The stomach is usually much dilated; peristaltic restlessness is at times visible. A sensation of fullness is felt in the lower right abdomen above the umbilicus, but no definite focal point is felt. The liver is not enlarged; there is no jaundice; no vomiting of bile. The attack usually terminates in a few days. The attack is usually recurrent and may be followed by a permanent

abdomen is usually more to right side over liver and radiating to right shoulder, very intense, frequently necessitating relief by morphine. Vomiting is not usually present; if present the vomit contains the last meal but no food from the day before; the vomiting usually is without much influence on the attack. The stomach is usually not especially dilated. Gastric peristalsis not visible. Examination of stomach in fasting condition shows that the organ is empty or contains only a small amount of gastric juice with or without bile. The liver is usually enlarged, both upward and downward. Icterus is present at times, fever is usually present. The attack is more frequent in women.

8. **Trachoma.**—Carhart observes that the surgical treatment of trachoma is the most effective way of combating the disease. Expression is safe and effective, it shortens the duration of treatment in a marked degree. The operation can be performed under cocaine, but in severe cases and in intractable children ether and gas are preferable. Adhesions in the lids should be separated with the probe daily until the tissues of the lids have healed. The reaction caused by the operation yields readily to ice cloths applied to the lids, and the resulting traumatic conjunctivitis can be controlled in a few days with a silver salt. The after treatment is most important to attain complete cure and to prevent recurrence, and should continue some weeks.

#### THE JOURNAL OF NERVOUS AND MENTAL DISEASE

June, 1908.

1. Presidential Address: The Mental State in Chorea and Choreiform Affections, By CHARLES W. BURR.
2. The Symptom Complex of Occlusion of the Posterior Inferior Cerebellar Artery: Two Cases with Necropsy, By WILLIAM G. SPILLER.

1. **The Mental State in Chorea and Choreiform Affections.**—Burr says that it is often stated and has been put in many textbooks that everyone suffering from Sydenham's chorea presents mental symptoms. This is true in so far that patients suffering from even mild attacks show peevishness, fretfulness, some loss of the power of fixed attention, and increased selfishness, but it is not true that every case presents mental symptoms of such moment as to raise doubt of the patient's sanity. The majority of the patients are entirely sane throughout the course of the disease. The severity of the mental symptoms varies greatly in different cases, and a series can be made showing each case a little more severe than the preceding and a little less severe than the succeeding one. Patients in whom the motor disturbance is very slight rarely if ever present serious mental symptoms, but the converse is not true, for even though the motor symptoms are very severe, the mental upset may be relatively slight. He has never seen a patient with so called paralytic chorea, in whom severe or permanent mental symptoms occurred. Though there are no sharp lines dividing the cases they may be separated, so far as the mental symptoms are concerned, into the following groups: First (and this includes a large majority), patients in whom there is peevishness, fretfulness, some loss of the power of fixing the attention, and a slight loss of the moral sense shown by disobedience and selfishness. Second, those

showing in addition to the above symptoms night terrors and transitory visual, auditory, or other hallucinations. Third, those with distinct delirium, wild or mild, accompanied with fever. Fourth, and this group is very small when we remember how common chorea is, those showing stupor or rather stupidity and an acute dementia which may follow the condition described under three or appear without any preceding mental symptoms at all severe, and which is usually accompanied with trouble in articulation not caused by choreic movements of the lips and tongue but the result of mental hebeteude. Fever is usually present for a time at least. Patients of the first and second groups almost always recover mentally and physically; those of the third group frequently die, and those of the fourth usually either die or, recovering from the chorea, remain demented. Though the chorea of childhood is an acute disease lasting only a few months, sometimes we see patients whose symptoms are at the beginning indistinguishable from chorea but who continue ill for several years or indeed for life without intermission. In these chronic cases severe mental degradation does not always follow, but frequently there are marked and permanent mental and emotional disturbances. Sometimes the movements cease entirely without mental improvement. They may be classed as instances of the chorea of degenerates. Though Sydenham's chorea is ordinarily a disease of childhood and adolescence, cases occasionally occur even in the aged. More frequently, however, than true chorea in old people is the appearance of localized choreic movements caused by focal brain disease. Thus before or after an attack of apoplexy there may be in the paralyzed part or the part later paralyzed choreic jerking. These when typical differ from athetoid movements, but sometimes it is hard to decide which to call them. The lesion is usually immediately behind or in front of the motor tract in the internal capsule or else involves the optic thalamus. Sometimes the movements become general.

#### ZENTRALBLATT FÜR CHIRURGIE.

May 2, 1908.

1. The History of Ether Anesthesia, By M. HIRSCH.
2. A New Method for the Diagnosis and Treatment of Fistulae, By E. G. BECK.

2. **Treatment of Fistulae.**—Beck has found that by the injection into a sinus or fistula of a liquid paste of bismuth and petrolatum every part of the sinus will become distinctly visible under the Röntgen ray. The best results are achieved if stereoscopic pictures are taken. Operative intervention becomes certain and positive in its results. By the use of a second paste, the sinus or fistula often heals without further treatment. The formula of the "diagnostic paste" is:

Bismuth subnitrate, ..... 1 ounce;  
White petrolatum, ..... 2 ounces.

The formula of the paste for treatment is:

Bismuth subnitrate, ..... 1 ounce;  
White petrolatum, ..... 2 ounces;  
Soft paraffin, .....  $\frac{1}{16}$  of an ounce;  
Iodine, .....  $\frac{1}{16}$  of an ounce.

1. The Temporary Opening of Both Upper Jaws (Kocher), By J. C. REINHARDT.

2. The Treatment of Bony Ankylosis of the Elbow Joint by the Transplantation of an Entire Joint,

By P. BUCHMANN.

**2. Transplantation of Joints.**—Buchmann, in two cases of bony ankylosis of the elbow joint, resected the joint and transplanted the first metatarsophalangeal joint, which he selected on account of its powers of extension and flexion with practically no lateral movement. He concludes that joints can be transplanted as easily as the long bones. The resection of the elbow joint must be quite broad between the head of the radius and the condyles of the humerus. Suture of the bone is unnecessary. The motions of the new joint are painless to as great an extent as the contracted muscles permit. No bad results to the foot follow the extirpation of the first metatarsophalangeal joint. In the two cases operated on, the results were good.

#### ZENTRALBLATT FÜR INNERE MEDIZIN

May 9, 1908.

- I. The Treatment of Infectious Meningitis,

By V. ARNOLD.

**1. Treatment of Meningitis.**—Arnold concludes a lengthy paper as follows: In the treatment of continuous vomiting in protracted cases of meningitis, he found that the administration of hydrochloric acid was exceedingly beneficial, while the giving of morphine usually caused the vomiting to increase, as it brings about a stagnation of the gastric contents and delays the emptying of the stomach. In several cases of the infectious type of meningitis, the epidermatic employment of guaiac brought about a diminution of the meningeal symptoms in a few days and in a short time apparently cured the disease.

1. New Modification in the Operative Treatment of Some Rectovaginal Fistulae, By D. VON OTT.

2. Spirochæta Pallida in Congenital Syphilis,

By C. GROUVEN.

3. Diagnosis of Embryonal Ovarian Teratoma from Anal Discharges, By F. UNTERBERGER.

4. Antithyreoidin (Möbius) in Osteomalacia,

By R. HOFFMANN.

5. Fatal Gangrenous Appendicitis in Pregnancy,

By F. FROMM.

**2. Spirochæta Pallida.**—Grouven has had positive results in the examination of the organs, mucous and skin lesions, and ascitic fluid in nineteen infants suffering from congenital syphilis. He found the organisms in the peniculus lesions of the hand, in papules on the cheeks and scrotum, in rhagades at the angle of the mouth, in the liver and lungs, and in sections of most of the internal organs.

**4. Antithyreoidin in Osteomalacia.**—Hoffmann draws attention to the many similar features existing in Graves's disease and osteomalacia. Starting from this premise, he gave a patient suffering from the latter disease injections of Möbius's antithyreoidin serum with almost magical results. Up to the present time the patient has remained well. The author says that if intravenous injections are not considered judicious, intramuscular injections of Möbius's serum or of an artificial preparation may be given, Meltzer having shown that the intramuscular method is equally efficacious with the intravenous.

## Proceedings of Societies.

### AMERICAN GYNÆCOLOGICAL SOCIETY.

*Thirty-third Annual Meeting, Held in Philadelphia on May 26 and 28, 1908.*

The President, Dr. J. MONTGOMERY BALDY, of Philadelphia, in the Chair.

### IMMEDIATE *versus* DEFERRED OPERATION FOR INTRA-ABDOMINAL HÆMORRHAGE DUE TO TUBAL GESTATION.

Dr. FLORIAN KRUG, of New York, remarked that the truth was usually to be found in the moot points of surgical practice, as in other matters, in the middle course, when opinions were diametrically opposed to each other. This was also true with reference to all that might relate to the welfare of the patient in such cases. From this proposition it followed that in a given case of ectopic gestation we could not say that an operation might be almost indefinitely deferred, nor, on the other hand, should we assert magisterially that a patient should be subjected to an immediate operation in every case, even though the diagnosis had been established beyond any reasonable doubt. The severity of the shock was not always proportionate to the quantity of blood lost. In fact, there was only a small percentage of cases in which death actually occurred from hæmorrhage. Not infrequently the injury which might be due to hæmorrhage was intensified by curetting, by forcible palpation of the abdominal wall and by other unjustifiable violence. In general it might be remarked that, if a case had resulted fatally, it might be due to the fact, either that suitable surgical aid had been wanting, that it had been ineffective, however skilful, or that it was ineffective because proper preparations had not been made.

Dr. F. F. SIMPSON, of Pittsburgh, remarked that the usual experience in these cases was that the first hæmorrhage was seldom alarming. It was at this time that a diagnosis should be made, followed by an operation as expeditiously as circumstances would permit, under favorable elective conditions. The teaching that rupture occurred infrequently with the primary hæmorrhage was harmful from the fact that those who were inexperienced were apt, on account of such teaching, to minimize the danger of the situation until a second or third hæmorrhage had brought the patient almost to death's door. With a patient in such a condition, there was of course little vitality remaining to sustain a severe or prolonged operation.

Hæmorrhage from rupture should rarely be fatal if the treatment was prompt and fairly intelligent. Such treatment was followed by low mortality, and such a result should be expected with a reasonable degree of confidence if precautions suitable to the situation were not overlooked.

Dr. H. N. AINSWORTH, of New York, believed that there was great variation in the quantity of blood which was effused within the peritoneal cavity. In the large majority of cases it was not sufficient to be a direct menace to the patient's life. The question of operation should be governed by the circumstances in each individual case, and the operation should be immediate or deferred, as the condition of

the patient demanded. In the cataclysmic cases in which the outpouring of blood was sudden and colossal, the abdominal cavity would quickly become filled with blood, and death from anæmia would be threatened. In addition, there was the unfavorable influence of pressure upon the diaphragm, with resulting compression of the heart and lungs. Notwithstanding the condition of shock in such cases, an immediate operation was absolutely imperative, and if the operation was reinforced by the intravenous infusion of saline solution, suitably administered, an impending fatal result might occasionally be averted. In cases of this character the hæmorrhage and shock could not be considered as contraindicating the operation any more than the secondary hæmorrhage which might have followed any serious surgical procedure. The indication was for action of the most prompt and intelligent nature.

Dr. E. E. MONTGOMERY, of Philadelphia, observed that hæmorrhage might result from rupture of the tube, from perforation of its wall by the development of the chorionic villi, or by partial detachment of the fetal sac, with hæmorrhage into the peritoneal cavity through the abdominal end of the tube, with hæmorrhage into the uterus, or retention of the blood within the tube. Or the fetus and its sac might escape intact into the abdomen in the well known condition of tubal abortion. In all these conditions hæmorrhage was an essential factor, but it did not follow that a fatal result would ensue even if an operation was not performed. In the cases which were treated with electricity a generation ago, and in which the diagnosis was not made until after rupture had taken place, it was supposed that the clot which had formed underwent absorption as the result of the electrical current. It was not improbable that the same result would have taken place if the electricity had been omitted. The formation of the clot was Nature's method of relieving the situation, the diminished arterial tension being a further assistant to this conclusion. In cases which did not receive surgical attention, and in which a clot did not form, death necessarily resulted from excessive loss of blood, and coroners' physicians in large cities had reported many cases of this character. It was just as important in the cases of severe hæmorrhage to ligate the bleeding vessel securely as it was in cases in which the hæmorrhage was upon the surface or in any other portion of the body. Stimulants must not be used in such cases unless the bleeding vessel had been secured, as increase of cardiac and arterial tension would be followed by recurrence of the bleeding.

Dr. C. C. FREDERICK, of Buffalo, considered that the necessity for an immediate operation was rarely present. The diagnosis in the majority of cases of tubal hæmorrhage was made days or weeks after the primary rupture, and in only a minority of the cases was the loss of blood really dangerous to life. In most of the cases the bleeding stopped after a short time, but recurred, with manifestations of shock, at more or less frequent intervals. Examination of the hæmoglobin index at frequent intervals and red blood counts were the most effective measures for determining whether the bleeding was progressive. If the manifestations of shock continued and the examination of the blood showed progressive anæmia,

an immediate operation should be performed, the circulation being stimulated with normal salt solution, adrenalin, etc. If the hæmorrhage had ceased, it would be safe to wait, the patient being stimulated in the meantime and effectively prepared for a suitable operation.

Dr. GEORGE T. HARRISON, of New York, believed that the general surgical principle to ligate any vessel which was sufficiently large to cause free hæmorrhage when divided should obtain in this condition. Even though the patient was in profound collapse, it would be necessary to operate, for if this was not done the chance might be forever lost. The dangers which were associated with delay were also of such magnitude that we were never safe in exposing a patient to such chances.

Dr. EGBERT H. GRANDIN, of New York, was of the opinion that this condition was surpassed in malignancy only by carcinoma. The longer one waited the more dangerous it was likely to become. It was illogical as well as unsafe to wait and see whether hæmorrhage would or would not recur. If, however, the patient was in collapse, it was probable that active hæmorrhage had ceased, in which case it was well to wait until she rallied and then operate at once, and always by the abdominal route. It was not advisable to stimulate the patient until after the abdomen had been opened and the bleeding arrested. Intravenous injection of saline solution, while it might stimulate the patient, would also increase the blood pressure and thereby increase the danger of hæmorrhage. The longer the delay after hæmorrhage had ceased the greater the risk of severe complications, and consequently the higher the mortality rate. In the cases in which hæmatocœle had formed, it was permissible to operate by vaginal incision and remove the clots. The abdomen might then be opened if the condition of the patient would warrant it, and the injured broad ligament excised.

Dr. W. P. MANTON, of Detroit, advised that in every case the condition of the patient and the surroundings and facilities for an operation be carefully considered. No fixed rule could be laid down, each case being governed by the conditions present. Judgment fortified by experience was imperative in every case before attempting to interfere surgically.

Dr. A. LAPHORN SMITH, of Monreal, had had an experience of forty-one cases, with two deaths. He believed that no case was too desperate for an attempt to relieve it by surgical measures. He believed that the diagnosis of tubal gestation could in some instances be made before rupture had taken place. Even if the patient was unconscious from loss of blood, it was proper to operate without waiting for rallying, for that might mean a renewal of the hæmorrhage. It was far preferable to open the abdomen, tie the bleeding vessel, and replace the lost blood with normal salt solution.

Dr. B. F. BAER, of Philadelphia, accepted the surgical principle that it was always imperative to secure a bleeding vessel wherever located. This rule was entirely applicable in the hæmorrhage from a ruptured tubal gestation sac. If a patient was in profound collapse, there might be a doubt as to whether bleeding was still in progress, and in such a case it might be wise to devote a few hours to the application of restorative measures.

Dr. HERMAN J. BOLDT, of New York, thought that much would depend upon the judgment of the physician in the management of each individual case. It was very important to distinguish between the primary and the secondary hæmorrhage in the choice of the procedure to be followed. As a rule, the sooner an operation was performed in a case of tubal abortion the better, remembering, however, that it was generally regarded as unsafe to inflict additional injury while a patient was still suffering from shock. If the patient was improving, he thought it better to wait and carefully observe the situation. If there was any evidence of renewed hæmorrhage an operation should be performed at once and concluded as quickly as possible. In these extreme cases intravenous injections of saline solution should be given, and a tourniquet used upon the lower extremities. Saline solution should also be poured into the peritoneal cavity, and no time lost in trying to find the embryo. The patient should be operated upon at her home, if possible, to avoid the danger of transportation. If a patient was rallying, it did not mean that the necessity for an operation was passed. The only cases in which postponement was permissible were those in which an hæmatocele had manifestly formed. In general, if symptoms of hæmorrhage were present, it was wise to operate at once.

Dr. A. MARTIN, of Berlin, Germany, thought that the bleeding in this condition should be treated on surgical principles, dilatory tactics being entirely inadmissible. Whether the operation should be done immediately at the patient's home or after removal to a hospital would be governed by the condition of the patient at the moment she was seen. The abdominal route was to be preferred for the operation.

Dr. SETH C. GORDON, of Portland, Me., had performed his first operation in 1887, twelve hours after rupture had occurred, and the patient recovered. He had operated by the vaginal route, but thought the abdominal route preferable. If the symptoms in a given case were ameliorating, he was disposed to wait, keeping the patient under careful observation. Shock and hæmorrhage in these cases he considered synonymous.

Dr. E. C. CUSHING, of Boston, recognized that there were some cases in which severe symptoms were wanting. The diagnosis in such cases was dependent upon the presence of an hæmatocele. If severe symptoms were absent, temporizing was allowable, and some cases would do well if nothing at all was done. Recent experiments had shown that the hypodermatic injection of rabbit's serum might be very effective in cases in which the hæmorrhage had been profuse.

Dr. HENRY RORR, of Cleveland, advocated more conservatism in the treatment of this disease. Even if one was satisfied that the diagnosis of internal hæmorrhage was correct, an operation could frequently be deferred. This was certainly desirable in cases in which shock was present. In many instances the hæmorrhage was not of a dangerous character.

Dr. WESLEY M. BORR, of Washington, thought that every case of this condition was a surgical one and required surgical treatment. This was emphasized by the difficulties and complications. Even if

the hæmorrhage ceased, the possibility of its recurrence must be remembered.

Dr. ANDREW F. CURRIER, of Mt. Vernon, N. Y., thought any further statement could only be a repetition of what had already been said, pro or con. Men usually grew conservative as they became older, but he felt that for this condition the radical position was the proper one. Being a surgical condition, it demanded surgical treatment. The diagnosis of internal hæmorrhage being made in any case, we were bound to know the cause and remove it if possible. The abdominal route seemed to him the only safe one. His only experience with the vaginal route had been in cases in which an ineffectual attempt had been made by others to relieve the situation by that procedure, greatly increasing the difficulties and complications which already existed.

Dr. H. EHRENFEST, of St. Louis, expressed his preference for an immediate operation in all cases in which the diagnosis was clear.

Dr. F. PFANNENSTIEL, of Kiel, Germany, thought this condition should be treated in accordance with the general surgical law and with as little delay as possible. As soon as the diagnosis was made, preparations for an operation should be begun and the patient placed under conditions which would most conduce to her recovery.

Dr. BROOKS H. WELLS, of New York, believed in an immediate operation if possible, otherwise with the slightest amount of delay.

Dr. J. TABER JOHNSON, of Washington, supposed that this was a settled question and could only regard its reopening as a step backward. If this society gave out an uncertain note, its effect would be disconcerting upon the profession at large. He did not think an argument upon a matter of this kind could be based upon experiments upon dogs. As to unruptured tubal gestation sacs, the diagnosis was difficult, but could be made, and he believed that when it had been made an operation should be performed at once. A waiting policy was too often fatal. One could never predict the complications which might arise. It was unwise to assume that hæmorrhage had ceased. Even if it had ceased, an hæmatocele was by no means a desirable condition.

Dr. GARDINER, of Montreal, admitted that he was of the number who had formerly made use of electricity for this condition, and as he then believed, with good results. We should not forget those who had done the pioneer work leading up to the present situation. He was free to say that he leaned to the conservative side of this question. The rule was a safe one that we should be guided by the circumstances which were present in each particular case.

**The Heart in Shock.**—Dr. E. ROISE, of Grand Rapids, Mich., stated that it was generally conceded that the danger in connection with shock arose from the very low blood pressure, which was supposed to be due to vasomotor paralysis. This was the theory of Cole, but his conclusion was erroneous. Howell thought that the low blood pressure in cardiac shock was due to an adrenergic exhaustion. Henderson thought that it was due to deficiencies of carbon dioxide in the blood, and that when death occurred suddenly in shock the heart was tetanically contracted. The author had demonstrated experi-

mentally that the heart in a state of shock was in tonic contraction, varying in degree with the degree of the shock, the veins being filled and the arteries in spasm. Veratrum, when given in such cases, irritated the peripheral nerves and caused toxic symptoms. Adrenalin, when introduced into a vein, relaxed the heart and so relieved the overfilled veins. The dogs upon which these experiments were performed were partially anesthetized with chlorotone, no ether being given.

**Pernicious Anæmia of Pregnancy.**—Dr. P. FINDLEY, of Omaha, stated that this rare disease was first described in 1842, then at intervals until 1871, when five cases were carefully reported, all of which ended fatally. Most of them were well prior to pregnancy; abortion occurred in some of the cases, but all the women who went to term died shortly afterward. No explanation had been found for its occurrence during that period. It was usually announced by hæmorrhage and shock during the second half of pregnancy. Some of its symptoms were constipation, vertigo, loss of reflexes, and diminution in the red cells. There was no diminution in the hæmoglobin, and the lymphocytes were not increased in number. At the autopsy the organs were all found to be anæmic, with hæmorrhage into their tissues. In some of the cases there was improvement for a time, and labor sometimes came normally, but the child usually died *in utero* and the mother a few hours or days after delivery. The diagnosis was made by the examination of the blood.

Dr. R. C. NORRIS, of Philadelphia, had seen but one case in 3,000 labors. In this case the blood did not clot and persistently oozed through the uterine packing. Death occurred after forty-eight hours. Adrenalin was administered, but without benefit.

**Suggestions in Teaching Gynæcology, with the Demonstration of Special (Mechanical) Charts as an Aid in this Work.**—Dr. J. A. SAMPSON, of Albany, N. Y., observed that three phases in the study of any of the clinical branches of medicine naturally suggested themselves: 1. The study of each disease as a science, including its ætiology, the anatomical changes in its different stages, and the elucidation of its symptomatology. 2. The classification of symptoms and the study of their various causes, with the modes of distinction. 3. The art or technique of the clinical branch of medicine, including the taking of histories, physical examination, diagnosis, and treatment, also practical experience gained in dispensaries, hospital wards, and the private practice of instructors. The student should attempt to solve the problems associated with each disease from his knowledge of the normal anatomy and physiology, rather than by memorizing data obtained from lectures or textbooks. In the solution of such problems questions were asked, and the students' answers were corrected when necessary and supplemented by information which they could not be expected to reason out. Various apparatuses might be employed, including drawings, models, or specimens obtained by operation or at autopsy, according to the requirements of the given lesson. Medical charts had been found of great value in this work by the author, and a large number were ex-

hibited graphically depicting the various pelvic organs and their functions.

Dr. MARTIN was in favor of all methods of teaching which brought out the subject matter with vividness. He had been accustomed to have his students make sketches of that which they found by clinical examination, and this habit was often continued with great value through their professional life. He had always found the touch clinics, which were not so common in this country as in Europe, of the greatest value to students. He called attention to his manikin, made from the human pelvis and provided with various anatomical preparations, as a useful means of teaching the anatomical portion of gynæcology.

Dr. J. RIDDLE GOFFE, of New York, was of the opinion that correct principles of teaching had been brought forward by Dr. Sampson. The important point for the student was to obtain an indelible mental picture of the organs and tissues which he might be examining. As aids in acquiring information the manikin, the chart, and the blackboard were all useful.

Dr. MIER, of Philadelphia, described the method of clinical instruction at Jefferson College and referred in particular to the half hour before each gynæcological operation, which was devoted to examination of the patient to be operated upon by a suitable number of students.

**Hospital Gynæcology.**—Dr. ROBERT L. DICKINSON, of Brooklyn, spoke of the gynæcological service as a separate department in a hospital, and believed that in every hospital of any considerable size this distinction should be made. The obstetric cases and the cases of pelvic disease should in such hospitals be entirely under the care of one who was distinctly a gynæcologist. The list of diseases should include all the urinary bladder diseases and those of the rectum as they occurred in women. Gynæcological patients should be isolated as far as possible, and unnecessary exposure and examinations avoided. The hospital internes should be allowed the greatest amount of practical work consistent with the efficiency of the service. The best results would be obtained when the chief of the hospital internes was paid for his services and his position made more or less permanent. The ordinary hospital histories were too complicated and deficient in system. The written history should be simple, though comprehensive, its object being an aid to treatment, not a scientific dissertation upon the given disease. Hospital regulations should all be in print, clearly displayed, and rigidly adhered to without exception.

**The Surgical Treatment of Prolapse of the Uterus and Bladder.**—Dr. J. S. STONE, of Washington, remarked that the first to develop the principles upon which this treatment was based was Simon. It was also associated with the principles enunciated by Tait in his flap splitting method. Hadra, too, had devised a method by which the vagina was dissected and attached at about the level of the os internum. The influence of Sænger in this field had also been very important, and the same was true of Stoltz and Mackenrodt. The work of Sims, Emmet, and Martin had been significant in

the evolution of the problem. An operation for cystocele was seldom complete without a simultaneous operation on the perineum. It was seldom necessary to amputate the portio vaginalis. The older methods of operating by removing strips of tissue from the anterior wall were entirely inefficient. The entire relations of the vagina to the prolapsed uterus must be changed and brought back as nearly as possible to the normal. In extreme cases it would be necessary to open the peritoneum, bring forward the broad ligaments, and attach them to the anterior wall of the uterus.

Dr. PFANNENSTIEL emphasized the great importance of this method of treatment and described by means of drawings the method which he was accustomed to use. He did not favor the methods in which the round ligaments were instrumental in relieving the prolapsus, believing that the support which they gave was insufficient.

Dr. GOFFE believed that the organs of the pelvis were sustained by ligaments, the same as other viscera, and that any method for relieving prolapsus must take into account this fundamental principle. In the relief of cystocele it would therefore be essential to operate directly upon the ligaments by which the uterus and bladder were sustained. Thus, the round and uterosacral ligaments should be shortened and the bladder then hung by three sutures to the top of the uterus. Of course the pelvic floor was also to be reconstructed.

Dr. MARTIN described the evolution of his work upon this problem during the past thirty years. The recent suggestions, including Pfannenstiel's, relating to the support of the bladder, were very important; also the method by which the uterus was brought forward and secured under the bladder. In order to get a permanent result in this condition, all the organs in the pelvis must be corrected. Treatment in some cases must be continued six or seven years. A point which was often overlooked was the proper treatment of the general nutrition. If the tissues were all in bad condition, permanent results from operations could hardly be expected. In very aged women who suffered with this condition the uterus and annexa should all be removed.

Dr. CHARLES P. NOBLE, of Philadelphia, stated that the condition of cystocele was but a small part of the problem involved in prolapsus as stated by Martin. Only by very free detachment of the bladder and uterus from their surroundings could effectual repair be accomplished. The problem was a complex one in almost every case and demanded a series of procedures.

**Endometritis Exfoliativa.**—Dr. H. EHRENFEST, of St. Louis, stated that this condition had been carefully studied and described by Lingelmann. The membrane which was discharged was quite different from a decidua, and was not at all influenced by section or mummifying abortion. It occurred only with menstruation and must be regarded as an epithelial relief hematoma containing many blood cells. The exfoliation of the membrane was partial and it contained much glandular and interglandular tissue. It was merely an exaggeration of the normal menstrual membrane. The separation of the membrane was accomplished by the effusion of blood beneath it and by the contraction of the uterus. There was no inflammatory process, but

there was a rich development of spongy interglandular material.

**Operations for the Relief of Pelvic Disease in Insane Women.**—Dr. L. BROWN reported the operations which he had performed during the past five years at the Manhattan State Hospital. The existing pathological conditions alone were considered, the mental condition being disregarded. The character of the mental condition in the majority of cases was unfavorable to recovery. It was believed that such patients had a right to relief when they were the subjects of pelvic disease. The class of patients in which there was stimulus to mental recovery had that type of insanity which was known as "manie depressive." The best results were obtained in cases in which the mental disturbance had not become a fixed habit. The character of the operation did not appear to bear any relation to the resulting mental improvement. Thirty-two patients showed great improvement mentally after the performance of an operation and were ultimately cured. The mental improvement following the operation was believed to be due to improvement in the physical condition.

Dr. W. P. MANTON, of Detroit, had worked in the field covered by the paper for twenty years, and was still an investigator. The good results which had been obtained were not due to the operation alone, that being but a single factor. It must be admitted that in many of the cases the improvement had been only temporary.

Dr. DICKINSON reported three cases of nymphomania which had been cured after the performance of hysterectomy and ovariectomy.

(To be continued.)

## Letters to the Editors.

### THE "JUNGLE PLANT."

BAKERTOWN, PA., June 1, 1908.

To the Editors:

Referring to the notes of Dr. Silkworth, page 1032 of the *Journal*, on the "jungle plant" (*Commobretum sundiacum*), it will be of service to know if in any of the six reported cures the subjects relapsed to their former condition in the near future.

This new opium cure is not yet two years old, but it has been used very extensively throughout Malaysia, among Chinese, Malays, and others, in some instances with apparently very gratifying results. Thousands are reported to have been cured, with many relapses.

How much the drug helps toward a cure can hardly be definitely determined at present. It is probable that the process of roasting deprives the plant of much of its medicinal value, and the burnt residue may act only as an astringent, relieving the sufferer of his violent diarrhoea, while the burnt opium, coupled with the determination to quit its use, really effects a cure.

Here is a good field for investigation. The cost of 1500 pounds (14 pounds of the dried leaves only, one or two dollars apiece in India, Ceylon, Malacca, and the Malay States).

W. J. KENNEDY.

## New Inventions.

### A NEW PLIABLE SUBMUCOUS ELEVATOR.

By HUGH BURKE BLACKWELL, M. D.,  
New York.

The instrument here illustrated is eight inches long and silver plated throughout. It is composed of a solid steel, octagonal handle, tapering at the sides towards the extremities. Attached to each end of the handle, or middle piece, is a partially hardened copper blade, one blade being used as a sharp elevator, the other as a dull one.

The blades of the instrument are pliable and may be bent at any angle according to the degree of septal deviation, and yet they possess a sufficient amount of rigidity to hold that angle while the operator elevates the mucoperichondrium beyond the point of deviation.

In shape the blades of the instrument resemble those of the Killian elevator, but differ in being pliable and somewhat heavier. The silver plating

Pliable Submucous Elevator.

prevents the formation of cracks in the smooth surface of the blades, and in no way interferes with its proper sterilization. It is made by George Tiemann & Co.

The value of the instrument in diminishing the danger of perforations is at once apparent, especially while elevating the mucoperichondrium and mucoperiosteum immediately behind a sharp angle of deviation.

The blades of the elevator can be readily bent to conform with the surface of any deviated septum, and yet retain rigidity sufficient to hold the curve imparted to them by the hand of the operator, while he elevates the mucoperichondrium or mucoperiosteum. Its continued use slightly increases the rigidity of the blades.

I have used the instrument in operating on the past thirty-one cases of submucous resection of the septum, and have found it to be of practical value in my hands.

## Book Notices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

*Medical Gynecology.* By HOWARD A. KELLY, A. B., M. D., LL. D., F. R. C. S. (Hon. Edinb.), Professor of Gynecological Surgery in the Johns Hopkins University and Gynecologist to the Johns Hopkins Hospital, Baltimore, etc. With One Hundred and Sixty-three Illustrations. New York and London: D. Appleton & Co., 1908. Pp. xiv+662.

Dr. Kelly treats extensively of aetiology in this work, and we think he is to be commended for doing so, for not all the diseases peculiar to women are to be traced to parturition, gonorrhoea, or traumatism. In particular, we would direct attention to the chapter on acute infectious diseases as causes of pelvic disease, beginning on page 247. Deserved prominence

is accorded also to the eliciting and recording of case histories and to the details of diagnosis. The author is for the most part very clear in his statements, but the following sentence (page 303) seems rather defective: "The cervix in such cases is at a much lower point in the vagina than is normal, in fact that conditions seem almost reversed." We fancy that that is not what he meant to write.

In the matter of displacements of the uterus, we think that an unnecessary distinction is made between descensus and prolapse, and we regret to see that Dr. Kelly has such a poor opinion of the use of pessaries. There are many signs that a reaction has set in in their favor, but we must add that in our judgment most of the pessaries in use are exceedingly faulty. A remarkable feature of the book is its inclusion of an extensive essay on syphilis, covering more than fifty pages.

We find some verbal peculiarities that rather grate on us—for example, "deferinitis" (page 334) and "col tapiroides" (page 343). In the latter instance one is at a loss to know whether the author is using a Latin adjective to qualify a French noun, or whether both words are French, one in the singular and the other in the plural. These are small matters, but they appear to us to be blemishes all the same.

From the mechanical point of view, the volume has the excellent feature of lying open without the necessity of manual intervention, but we think the page is too wide (the lines too long) to be read easily. The paper, the print, and many of the illustrations are fine.

*Elements of Water Bacteriology.* With Special Reference to Sanitary Water Analysis. By SAMUEL CATE Prescott, Assistant Professor of Industrial Biology, and CHARLES EDWARD AMORY WINSLOW, Assistant Professor of Sanitary Biology, in the Massachusetts Institute of Technology. Second Edition, Rewritten. First Thousand. New York: John Wiley & Sons, 1908. Pp. xii+258 (Price, \$1.50.)

As the authors truly state, the most direct, accurate, and practical method of water examination at the disposal of the sanitarian is a bacteriological test. In this new edition they have included the advances that have been made in the past four years that bear on the practical investigation of sanitary questions connected with water supply, and notable additions have been made to the chapters on self purification, on the isolation of the typhoid bacillus, on the interpretation of the colon bacillus test, and on the significance of intestinal bacteria other than the *Bacillus coli*. A chapter has been added on the bacteriology of sewage and sewage effluents. The book is terse, practical, and of value to all health officers, sanitarians, and physicians engaged in practice in localities in which they must make their own examinations.

*A Manual of Venereal Diseases.* By the Officers of the Royal Army Medical Corps. Introduction by Sir ALFRED KEOGH, K. C. B., Director General of the Army Medical Service; History, Statistics, Invaliding, etc., by Lieut. Colonel C. H. MELVILLE, R. A. M. C., Secretary to the Advisory Board; Clinical Pathology and Bacteriology, by Colonel LEISHMAN, R. A. M. C.; Clinical Course and Treatment, by Major C. E. POLLOCK, R. A. M. C. London: Henry Frowde (Oxford University Press) and Hodder & Stoughton, 1907. Pp. x+282.

This little volume summarizes the chief features of the report of the subcommittee of the Army Medical

Advisory Board on the treatment of venereal diseases in the British Army. The original report is too bulky and contains too many details to be useful to the average medical officer. The essential points in the diagnosis and treatment of venereal affections have therefore been included in the present work. In the introduction, by Sir Alfred Keogh, emphasis is laid on the need of administrative control and of personal prophylaxis in the prevention of venereal diseases in the army. In speaking of prophylaxis, Lieutenant Colonel Melville does not mention such measures as the use of prophylactic injections, inunctions, etc., but mentions the disciplinary measures which are suggested as the best preventives of venereal infection among soldiers. In this he is, we think, on the wrong tack, for, while discipline may keep some men continent, it will not have much effect on most enlisted men, and will lead only to the concealment of their maladies.

The methods of examining secretions for the *Spirochaeta pallida* are briefly described by Leishman in a very interesting and practical chapter, in which there is also included a short sketch of the Wassermann serum reaction in syphilis. In the section on diagnosis Major Pollock gives a practical table of "values" of the different symptoms and manifestations. The values are arranged in order according to the number of "points" (as in bridge playing). The chapter on treatment includes the methods used in the British Army, with numerous tables and schemes for the treatment of men through the entire course of the disease. Mercurial cream is the favorite preparation for injections. The diagnosis and treatment of gonorrhoea and of soft chancre occupy very brief chapters at the end of the volume. There are a number of tables of statistics of venereal diseases in the British Army, a list of authorities consulted, and a formulary, together with forms, etc., for recording cases and keeping statistical returns for the use of the Advisory Board.

The book will prove useful to army surgeons as a guide to diagnosis and treatment, and might form the basis of a similar work for our own army and navy, modified to suit the methods in vogue in this country.

*Untersuchungen zur Kenntnis der psychomotorischen Bewegungsstörungen bei Geisteskranken.* Von Dr. KARL KESSEL, Assistenzarzt der Klinik für Nerven und Geistes-Erkrankheiten zu Halle a. S. Leipzig: Dr. Werner Klinkhardt, 1908. Pp. viii+171. (Price, M. 6.)

It is a pleasure to review this small book, for one finds in it, as it were, the spirit of the dead master to whom the author has dedicated it, Wernicke. An attempt is here made to analyze the disturbances in the motor functions in mental disorders in terms of the cerebral mechanisms. Psychomotor acinesia as seen in mutism, psychomotor apraxia, and psychomotor aphasia and tonic and hypotonic muscular symptoms are discussed in the light of mixed disturbances based on factors of modified innervation as influenced by psychical factors. External observations of psychomotor disturbances, of muscular coordination, show them to be conditioned by a type of altered innervation which, however, vary from similar modifications which have a basis in lesions of the sensorimotor areas, such as motor paralysis and ataxias, and in the cortical and transcortical apraxias and aphasias. Such modifications are in-

terpreted by the author as probably conditioned by disorder in the connections of the frontal lobes and the cerebellum, either in the terminal stations of such connections, in the coordinating fibre tracts themselves, or in the intermediate ganglia. In organic disorders of these structures, tonic muscular tension, prolonged contractural states, and hypotonia may also occur.

So far as the psychomotor symptoms of mental disease are concerned, the author predicts the probability that the disease process does not involve exclusively, or only in small degree, the cerebellofrontal system itself in its frontal portions, but that involvement takes place between the frontal and other brain areas in their transcortical connections. Two types of such transcortical disturbances are conceivable. Either a dissociation may take place between the cerebellofrontal system and the sensorimotor system of the central lobe, or there results a cutting off of the compound, complex motor apparatus of the sensorimotor and cerebellofrontal systems from its relations to other portions of the brain. In view of the wide diffusion of the mental disturbances, it is impossible to decide as to the more important of these two conceptions. In this modified manner we find Wernicke's sejunction hypothesis again made prominent. The monograph offers interesting hypotheses and is worthy of the attention of psychiatrists.

*La Diathèse urique.* Par HENRI LABBÉ, chef de laboratoire à la Faculté de médecine de Paris. Paris: J. B. Baillière et Fils, 1908. Pp. 95.

The author presents a review of the recent discoveries in physiology and biological chemistry which have added to our knowledge of the production and excretion of uric acid. He shows the latter in the purin group and its close relationship with xanthin, hypoxanthin, and caffeine. The agents that have an action on uric acid are classed as precipitants, that is, those that prevent its solution, and the solvents, that is, those that facilitate the acid's solution and excretion. Among the first are cold, acids, some metals and their salts, and the many substances that increase acidity or form insoluble compounds with uric acid. The solvents include sodium salicylate, piperazine, lyceol, aspirin, urotropin, and thymic acid.

The dietetic factors that augment or lessen uric acid formation are described, and the author believes that a dietary free from meats and those vegetables that contain purin will give the most favorable results in those who have migraine, gravel, or other uric acid disease.

*Die Entzündung, eine monographische Skizze aus dem Gebiet der pathologischen Physiologie.* Von Dr. KARL KROHN, gewöhnlicher Professor und Vorstand des Instituts für experimentelle Pathologie an der Universität zu Göttingen. Leipzig: Verlag v. K. K. Fischer, Universitäts- und Landhandlung, 1908. Pp. 100. (Price, M. 1.00.)

This "Festschrift" was written for the celebration of the anniversary of the University of Göttingen. The preface is signed "September, 1907"; and the essay is finally published in 1908.

The author gives us a short historical review of the development of our knowledge of inflammation, in which he places Cohnheim's name very rightly in the foreground. This is followed by a description

of the principal symptoms of inflammation, a review of the leading theories, such as have been expounded by Cohnheim, Stricker, von Recklinghausen, Weigert and Ziegler, Marchand, Metchnikoff, and others. The succeeding chapters deal with the causes and effects of inflammation, the physiological and pathological action of the blood, the leucocytes, etc., during inflammation, and the physical laws which influence inflammation, resorption, etc. Chapter X reviews our present knowledge of inflammation.

*Sul processo di riparazione delle perdite di sostanza nelle cartilagini e pericondrio.* Per il Prof. Dott. GIULIO ANZILOTTI, aiuto e libero di patologia chirurgica. Pisa: Orsolini-Frosperi, 1907. Pp. 38.

This experimental research upon the process of repair going on in cartilage, beginning in the perichondrium, demonstrates the proliferation of cartilage cells. Active caryocinesis goes on in those cells around the new cartilaginous "centres" which constitute the reparative material. Proliferation was noted especially in the groups of cells immediately underlying the perichondrium, but also in the deeper layers and in cartilaginous fragments adhering to the wounded perichondrium. The matrix also proliferates by hypertrophy of its fibrillar components, and thus the multiplying cartilage cells are gradually separated from one another. The author has not observed the transformation of connective tissue into cartilage directly, but in some instances fibrocartilage was first formed. And he has not found any ossification or calcification in the process of repair in cartilage. He emphasizes the low resistance of cartilage against traumatism and infection and its slow tendency to repair. These facts should teach the surgeon to remove diseased or necrotic cartilage widely to secure the best conditions for a reparative process.

*Morfologia delle arterie dell'estremità addominale.* G. SALVI. Parte I. Origine e significato delle arterie che vanno all'estremità (selaci, anibi, rettili, uccelli). Supplemento agli studi Sassaresi, anno v, 1907, sez. II. Sassari: G. Dessi, 1907. Pp. 53.

Salvi publishes in this pamphlet the result of ten years of study on the comparative anatomy of the arteries of the lower extremity at the Anatomical Institute of Sassari. The work does not offer anything of special interest to practising physicians, and consists of an analysis of the structure of the arteries of the lower limbs in reptiles, amphibia, etc.

#### Miscellany.

**Army Medical Department Examinations, 1908.**—The act of April 23, 1908, reorganizing the Medical Corps of the Army, gives an increase in that corps of six colonels, twelve lieutenant colonels, forty-five majors, and sixty captains or first lieutenants, and establishes a Medical Reserve Corps as an adjunct to the Medical Corps. Under this recent act, the lieutenants of the Medical Corps are promoted to the rank of captain after three years' service instead of five, and the increase in the higher grades insures promotion at a reasonable rate all through an officer's military career. Furthermore, applicants who are found qualified in the preliminary examination are appointed first lieutenants of the Medical Reserve Corps and ordered to the Army Medical School, in Washington, D. C., for eight months' instruction.

#### THE MEDICAL CORPS.

A preliminary examination for appointment in the Medical Corps will be held on August 3, 1908, and formal applications should be in possession of the War Department prior to July 1st. The applicant must be a citizen of the United States, between twenty-two and thirty years of age, a graduate of a medical school legally authorized to confer the degree of doctor of medicine, of good moral character and habits, and have had at least one year's hospital training or its equivalent in practice. The examination will be held concurrently throughout the country at points where boards can conveniently be assembled, and due consideration will be given to the localities from which applications are received, in order to lessen the traveling expenses of applicants as much as possible. The examination in subjects of general preliminary education may be omitted in the case of applicants holding diplomas from reputable literary or scientific colleges, normal schools, or high schools, or in that of graduates of medical schools which require an entrance examination satisfactory to the faculty of the Army Medical School. The large number of vacancies created in the Medical Corps by recent legislation makes it certain that all successful candidates will be recommended for a commission for several years to come.

#### THE MEDICAL RESERVE CORPS.

It is desired to obtain and maintain a list of qualified medical men all over the country who are willing to serve as medical officers in time of emergency, and to such men the President is authorized to issue commissions as first lieutenants, Medical Reserve Corps. It is recognized that it will be necessary to place only a limited number of these officers on the active list in time of peace, and it is hoped

that young medical men throughout the country and medical officers of the militia of the various States may be sufficiently interested to secure positions on the Medical Reserve Corps list. An applicant must be between twenty-two and forty-five years of age, a citizen of the United States, a graduate of a reputable medical school legally authorized to confer the degree of doctor of medicine, and have qualified to practice medicine in the State in which he resides. Examinations will be held in the near future and will embrace the practical medical subjects. Full information concerning the Medical Corps and the Medical Reserve Corps may be procured upon application to the surgeon general, U. S. Army, Washington, D. C.

**The Production of Deciduomata.**—Loeb points out a certain analogy which exists between these artificially produced deciduomata and a variety of multiple tumors that are limited to certain organs, as, for instance, multiple fibroneuromata, enchondromata, symmetric lipomata, or adenomata of the intestinal mucosa; they might be called multiple systemic tumors. The deciduomata represent a type of new formations which he designated "transitory tumors." If the substance were secreted by the ovaries continuously, instead of intermittently, the tumors would lose their transitory character and would become permanent new growths. In the case of the systemic tumors and of the deciduomata we have to deal with multiple benign tumors of a more or less transitory character affecting one organ or one tissue. We know that the origin of the deciduomata depends on two sets of conditions: (a) That a predisposing chemical substance be produced by a certain organ; and (b) that such a substance having been produced, indifferent stimuli, for instance, traumatism, are sufficient to produce the tumors. Clinical observation makes it likely that certain tumors, as, for instance, sarcomata, have at times been caused by traumatism. Experimentally, attempts to produce tumors through traumatism or through long continued irritation have never been successful. It may be suggested that such attempts could have been successful only if the necessary "preparatory" substance had been secreted prior to the action of the indifferent stimuli. Loeb states that he has found the definite cause for the formation of deciduoma, and he remarks that it is very desirable to emphasize certain similarities between the deciduoma and various other tumors in order to indicate the possible presence of predisposing "preparing" substances, as the unknown cause of certain tumors. Given such a "preparing" substance, otherwise indifferent stimuli would be sufficient to excite the potential proliferative energy of the tissues. The fact that the deciduomata degenerate as soon as the "preparing" substance ceases to be active is no valid reason for denying the designation "tumor" to these new formations. In order to indicate the ephemeral character of such new formations they may be called "transitory tumors." Even carcinomata may retrogress spontaneously. The presence of "preparing" substance can only explain the formation of a "transitory tumor," or, at the best, of a tumor that grows indefinitely in the same individual in which it originated, but it cannot explain the growth of a tumor which can be transplanted into many other individ-

als in which such a "growth" substance is not likely to be present. In order to explain on such a basis the inoculability of tumors we should have to assume the hereditary transmission of an increased energy of growth to the following generations of tumor cells, which thus would be able to continue to proliferate without the further presence of the growth substance in the inoculated animal. The possibility of such a transmission into later generations has not yet been established. Until such a proof has been given we must assume that transplantable tumors carry with them in the tumor cells or in their direct neighborhood the stimulus which enables them to proliferate in a new host. But it is quite possible that a nontransplantable tumor which originated through the action of a "preparing" substance may grow very rapidly and be, therefore, malignant. Transplantable tumors, on the other hand, do not need to be very malignant. The degree of inoculability and energy of tumor growth are two distinct properties which do not need to be associated in the same tumor. But the transplantability of tumors depends, in all probability, not only on the presence of a permanent stimulus in or near the tumor cells, but on some other factors, as yet unknown. The presence or absence of such secondary factors might determine the inoculability or noninoculability of a tumor, even if the essential cause in the tumor formation was the same in both cases.—*Journal of the American Medical Association*.

**The Survival of Typhoid Bacilli in Soil.**—As far back as 1889 it was shown by Grancher and Deschamps that from soil inoculated with a bouillon emulsion of typhoid bacilli the living organisms could be recovered after a period of five and a half months. Robertson, by the frequent addition of culture medium, was able to keep them alive in the soil for ten months. More recently, Lorrain Smith tried inoculating soil with an aqueous emulsion of the organisms, and found that, lacking the presence of the artificial culture medium, they lived a much shorter period. In his experiments twenty-one days proved the longest period that they were shown to exist. W. Mair has recently conducted some investigations which bear on this subject, although the object of his study was primarily to determine the effect on the soil as a habitat for certain organisms of sterilizing it by steam under pressure. The earth which he utilized was taken at a depth of three or four inches below the sod from the grounds of Queen's College, Belfast. It was inoculated with aqueous emulsions of the organisms and was kept under conditions of temperature, light, and moisture as closely simulating its natural surroundings as possible. Under these conditions, the living typhoid was shown to be present in a living state after eighty days, though there was no evidence that it was capable of multiplying and causing a secondary infection. The *Bacillus coli* communis was found after much longer periods. Some of his samples of soil were shown to be rendered much less suitable to the growth of the typhoid previously inoculated in an autoclave. This he attributed to the development of some heat-resistant forms. Of course different soils vary greatly in their suitability for the growth of various organisms, but the fact that it is possible

for the typhoid bacillus to live for eighty days in any soil under normal conditions is suggestive of the extent of the danger from certain methods of sewage disposal.—*Journal of the American Medical Association.*

## Official News.

### Public Health and Marine Hospital Service Health Reports:

The following cases of smallpox, yellow fever, cholera, and plague have been reported to the surgeon general, United States Public Health and Marine Hospital Service, during the week ending June 19, 1908:

Smallpox—United States.			
Places.	Date.	Cases.	Deaths.
Alabama—Mobile	May 23-30	1	1
California—Los Angeles	May 23-30	1	1
California—San Francisco	May 23-30	15	1
Illinois—Chicago	May 23-30	1	1
Illinois—Springfield	May 23-June 4	3	3
Indiana—Indianapolis	May 18-June 7	17	17
Indiana—Fort Wayne	May 23-June 6	1	1
Indiana—Terre Haute	May 10-June 6	1	1
Iowa—Ottawa	May 10-June 6	1	1
Kansas—Kansas City	May 30-June 6	5	5
Kentucky—Covington	May 30-June 6	1	1
Michigan—Grand Rapids	May 30-June 6	1	1
Michigan—Kalamazoo	May 30-June 6	2	2
Michigan—Saginaw	May 30-June 6	1	1
Minnesota—Winona	May 30-June 6	4	4
Missouri—Kansas City	May 23-June 6	10	10
Missouri—St. Joseph	May 23-30	8	8
Missouri—St. Louis	May 30-June 6	1	1
Nebraska—South Carolina	May 22-29	2	2
New York—Binghamton	June 1-8	1	1
New York—Niagara Falls	May 30-June 6	1	1
Ohio—Cincinnati	May 23-29	7	7
Ohio—Dayton	May 30-June 6	2	2
Tennessee—Knoxville	May 30-June 6	2	2
Washington—Tacoma	May 23-30	2	2
Wisconsin—La Crosse	May 30-June 6	1	1
Wisconsin—Milwaukee	May 23-30	6	6
Wisconsin—Racine	May 23-30	2	2

#### Smallpox—Foreign.

Arabia—Aden	April 27-May 18	10	10
Brazil—Rio de Janeiro	May 3-19	141	50
Canada—Halifax	May 31-June 6	6	1
Cape Colony—East London	May 18-25	1	1
Equador—Guayaquil	May 6-16	1	2
Egypt—Cairo	May 13-20	11	3
France—Paris	May 16-23	3	3

India—Rangoon	April 25-May 2	7	7
India—Smyrna	April 14-May 2	7	7
India—Suez	May 17-24	2	2
India—Tientsin	May 17-24	19	19
Straits Settlements—Singapore	April 25-May 2	39	1
Turkey—Bagdad	April 28-May 2	29	3
Turkey—Smyrna	April 14-May 2	7	7

### Army Intelligence:

Official list of changes in the stations and duties of officers of the Medical Corps of the United States Army for the week ending June 20, 1908:

LEWIS, W. F., Major. Left Fort Sill, Okla., for duty at Leon Springs, Texas.

MURPHY, P. B., Captain. Granted leave of absence for two months in the United States.

PERLEY, H. O., Lieutenant Colonel. Relieved from duty in the Philippines Division; will sail for the United States on October 15, 1908.

STONE, J. H., Major. Relieved from duty with the Army of Cuban Pacification; will sail on June 22, 1908, for Newport News, Va.

TRUBY, A. E., Captain. Ordered to accompany one-half of Co. B. H. S. from San Francisco, Cal., to Murray, Washington, for camp duty.

WHALEY, A. M., Captain. Granted leave of absence for three months, on completion of the manœuvres; left Jackson Barracks, La., for his proper station. Fort Sam Houston, Texas.

### Navy Intelligence:

Official list of changes in the stations and duties of officers of the Medical Corps of the United States Navy for the week ending May 16, 1908:

ALLEN, D. G., Assistant Surgeon. Appointed an assistant surgeon from June 15, 1908.

ENGLANDER, S., Pharmacist. Retired from the active service on June 15, 1908, on completion of thirty years' service, in accordance with a provision of the naval appropriation of May 13, 1908.

FARWELL, W. G., Passed Assistant Surgeon. Detached from the Lancaster and ordered to duty with Marines at Camp Elliott, Isthmian Canal Zone.

HAYWOOD, A. B., Assistant Surgeon. Detached from the naval recruiting station, Chicago, Ill., and ordered to duty with Marines at Camp Elliott, Isthmian Canal Zone.

KERR, W. M., Acting Assistant Surgeon. Appointed an acting assistant surgeon from June 12, 1908.

MAYERS, G. M., Passed Assistant Surgeon. Ordered to the Naval Medical School Hospital, Washington, D. C., for treatment.

MINK, O. J., Passed Assistant Surgeon. Detached from the Naval Medical School, Washington, D. C., and ordered to the naval recruiting station, Chicago, Ill.

SMITH, G. W., Assistant Surgeon. Appointed an assistant surgeon from June 15, 1908.

SNYDER, J. J., Passed Assistant Surgeon. Ordered to the New Hampshire.

THOMAS, G. C., Assistant Surgeon. Appointed an assistant surgeon from June 15, 1908.

WHITESIDE, L. C., Assistant Surgeon. Appointed an assistant surgeon from June 15, 1908.

ZIEGLER, J. C., Acting Assistant Surgeon. Detached from the Naval Hospital, Portsmouth, N. J., and ordered to the Naval Hospital, Pensacola, Fla.

## Births, Marriages, and Deaths.

### Married.

CHEETHAM—ROBINSON.—In Cleveland, on Thursday, June 18th, Dr. Arthur M. Cheetham and Miss Agnes May Robinson.

DOUGHERTY—MERKLE.—In Philadelphia, on Wednesday, June 17th, Dr. Clarence C. Dougherty and Miss Florence Lillian Merkle.

GILL—DUNHAM.—In Alloway, New Jersey, on Tuesday, June 16th, Dr. Walter W. Gill, of Westfield, New Jersey, and Miss Mary Claire Dunham.

MCCALLUM—THOMAS.—In Philadelphia, on Monday, June 15th, Dr. Chester A. McCallum, of Erie, Pennsylvania, and Miss Helen Ramsey Thomas.

### Died.

BARROWS.—In Hackensack, New Jersey, on Thursday, June 7th, Dr. Arthur A. Barrows, aged sixty-eight years.

BUSH.—In Warren, Pennsylvania, on Saturday, June 13th, Dr. John Bush, of Wahoo, Nebraska, aged fifty-two years.

CARLETON.—In Waterloo, New York, on Friday, June 19th, Dr. John F. Carleton, aged sixty-four years.

CORRY.—In Cadillac, Michigan, on Wednesday, May 27th, Dr. Winfield S. Corry, aged thirty-one years.

HURLEY.—In Norwood, Massachusetts, on Sunday, May 31st, Dr. Daniel M. Hurley, aged forty-four years.

KUNSTLICH.—In Passaic, New Jersey, on Sunday, June 21st, Dr. Alexander A. Kunstlich, aged sixty-four years.
